If the key function is expensive, it is possible to avoid repeated function calls by searching a list of precomputed keys to find the index of a record:

```

>>> data = [('red', 5), ('blue', 1), ('yellow', 8), ('black', 0)]
>>> data.sort(key=lambda r: r[1])           # Or use operator module
>>> keys = [r[1] for r in data]             # Precompute a list of keys
>>> data[bisect_left(keys, 0)]
('black', 0)
>>> data[bisect_left(keys, 1)]
('blue', 1)
>>> data[bisect_left(keys, 5)]
('red', 5)
>>> data[bisect_left(keys, 8)]
('yellow', 8)

```

('yellow', 8)

# array — Efficient arrays of numeric values

---

This module defines an object type which can compactly represent an array of basic values: characters, integers, floating point numbers. Arrays are sequence types and behave very much like lists, except that the type of objects stored in them is constrained. The type is specified at object creation time by using a *type code*, which is a single character. The following type codes are defined:

## ~~Multiple type codes~~ **Multiple type codes in bytes**

~~signed char~~

~~unsigned char~~

~~Unicode character~~

~~signed short~~

~~unsigned short~~

~~signed int~~

~~unsigned int~~

~~signed long~~

~~unsigned long~~

~~signed long long~~

~~unsigned long long~~

~~float~~

~~double~~

Notes:

1. It can be 16 bits or 32 bits depending on the platform.

*Changed in version 3.9:* `array('u')` now uses `wchar_t` as C type instead of deprecated `Py_UNICODE`. This change doesn't affect its behavior because `Py_UNICODE` is alias of `wchar_t` since Python 3.3.

*Deprecated since version 3.3, will be removed in version 4.0.*

The actual representation of values is determined by the machine architecture (strictly speaking, by the C implementation). The actual size can be accessed through the `array.itemsize` attribute.

The module defines the following item:

`array.typecodes`

A string with all available type codes.

The module defines the following type:

`class array.array(typecode[, initializer])`

A new array whose items are restricted by *typecode*, and initialized from the optional *initializer* value, which must be a list, a [bytes-like object](#), or iterable over elements of the appropriate type.

If given a list or string, the initializer is passed to the new array's `fromlist()`, `frombytes()`, or `fromunicode()` method (see below) to add initial items to the array. Otherwise, the iterable initializer is passed to the `extend()` method.

Array objects support the ordinary sequence operations of indexing, slicing, concatenation, and multiplication. When using slice assignment, the assigned value must be an array object with the same type code; in all other cases, `TypeError` is raised. Array objects also implement the buffer interface, and may be used wherever [bytes-like objects](#) are supported.

Raises an [auditing event](#) `array.__new__` with arguments `typecode`, `initializer`.

`typecode`

The typecode character used to create the array.

`itemsize`

The length in bytes of one array item in the internal

representation.

`append(x)`

Append a new item with value `x` to the end of the array.

`buffer_info()`

Return a tuple `(address, length)` giving the current memory address and the length in elements of the buffer used to hold array's contents. The size of the memory buffer in bytes can be computed as `array.buffer_info()[1] * array.itemsize`. This is occasionally useful when working with low-level (and inherently unsafe) I/O interfaces that require memory addresses, such as certain `ioctl()` operations. The returned numbers are valid as long as the array exists and no length-changing operations are applied to it.

### Note

When using array objects from code written in C or C++ (the only way to effectively make use of this information), it makes more sense to use the buffer interface supported by array objects. This method is maintained for backward compatibility and should be avoided in new code. The buffer interface is documented in [Buffer Protocol](#).

`byteswap()`

“Byteswap” all items of the array. This is only supported for values which are 1, 2, 4, or 8 bytes in size; for other types of values, `RuntimeError` is raised. It is useful when reading data from a file written on a machine with a different byte order.

`count(x)`

Return the number of occurrences of *x* in the array.

`extend(iterable)`

Append items from *iterable* to the end of the array. If *iterable* is another array, it must have *exactly* the same type code; if not, **TypeError** will be raised. If *iterable* is not an array, it must be iterable and its elements must be the right type to be appended to the array.

`frombytes(s)`

Appends items from the string, interpreting the string as an array of machine values (as if it had been read from a file using the `fromfile()` method).

*New in version 3.2:* `fromstring()` is renamed to `frombytes()` for clarity.

`fromfile(f, n)`

Read *n* items (as machine values) from the [file object](#) *f* and append them to the end of the array. If less than *n* items are available, **EOFError** is raised, but the items that were available are still inserted into the array.

`fromlist(list)`

Append items from the list. This is equivalent to `for x in list: a.append(x)` except that if there is a type error, the array is unchanged.

`fromunicode(s)`

Extends this array with data from the given unicode string. The array must be a type `'u'` array; otherwise a **ValueError** is raised. Use `array.frombytes(unicodestring.encode(enc))` to append Unicode data to an array of some other type.

`index(x[, start[, stop]])`

Return the smallest *i* such that *i* is the index of the first

occurrence of  $x$  in the array. The optional arguments *start* and *stop* can be specified to search for  $x$  within a subsection of the array. Raise **ValueError** if  $x$  is not found.

*Changed in version 3.10:* Added optional *start* and *stop* parameters.

`insert(i, x)`

Insert a new item with value  $x$  in the array before position  $i$ . Negative values are treated as being relative to the end of the array.

`pop([i])`

Removes the item with the index  $i$  from the array and returns it. The optional argument defaults to `-1`, so that by default the last item is removed and returned.

`remove(x)`

Remove the first occurrence of  $x$  from the array.

`reverse()`

Reverse the order of the items in the array.

`tobytes()`

Convert the array to an array of machine values and return the bytes representation (the same sequence of bytes that would be written to a file by the `tofile()` method.)

*New in version 3.2:* `tostring()` is renamed to `tobytes()` for clarity.

`tofile(f)`

Write all items (as machine values) to the **file object**  $f$ .

`tolist()`

Convert the array to an ordinary list with the same items.

`tounicode()`

Convert the array to a unicode string. The array must be a type 'u' array; otherwise a **ValueError** is raised. Use `array.tobytes().decode(enc)` to obtain a unicode string from an array of some other type.

When an array object is printed or converted to a string, it is represented as `array(typecode, initializer)`. The *initializer* is omitted if the array is empty, otherwise it is a string if the *typecode* is 'u', otherwise it is a list of numbers. The string is guaranteed to be able to be converted back to an array with the same type and value using `eval()`, so long as the **array** class has been imported using `from array import array`. Examples:

```
array('l')
array('u', 'hello \u2641')
array('l', [1, 2, 3, 4, 5])
array('d', [1.0, 2.0, 3.14])
```

# weakref — Weak references

**Source code:** [Lib/weakref.py](https://github.com/python/cpython/tree/3.11/Lib/weakref.py) [https://github.com/python/cpython/tree/3.11/Lib/weakref.py]

---

The **weakref** module allows the Python programmer to create *weak references* to objects.

In the following, the term *referent* means the object which is referred to by a weak reference.

A weak reference to an object is not enough to keep the object alive: when the only remaining references to a referent are weak references, **garbage collection** is free to destroy the referent and reuse its memory for something else. However, until the object is actually destroyed the weak reference may return the object even if there are no strong references to it.

A primary use for weak references is to implement caches or mappings holding large objects, where it's desired that a large object not be kept alive solely because it appears in a cache or mapping.

For example, if you have a number of large binary image objects, you may wish to associate a name with each. If you used a Python dictionary to map names to images, or images to names, the image objects would remain alive just because they appeared as values or keys in the dictionaries. The **WeakKeyDictionary** and **WeakValueDictionary** classes supplied by the **weakref** module are an alternative, using weak references to construct mappings that don't keep objects alive solely because they appear in the mapping objects. If, for example, an image object is a value in a **WeakValueDictionary**, then when the last remaining references to that image object are the weak references held by weak mappings, garbage collection can reclaim the object, and its corresponding entries in weak mappings are simply deleted.

`WeakKeyDictionary` and `WeakValueDictionary` use weak references in their implementation, setting up callback functions on the weak references that notify the weak dictionaries when a key or value has been reclaimed by garbage collection. `WeakSet` implements the `set` interface, but keeps weak references to its elements, just like a `WeakKeyDictionary` does.

`finalize` provides a straight forward way to register a cleanup function to be called when an object is garbage collected. This is simpler to use than setting up a callback function on a raw weak reference, since the module automatically ensures that the finalizer remains alive until the object is collected.

Most programs should find that using one of these weak container types or `finalize` is all they need – it's not usually necessary to create your own weak references directly. The low-level machinery is exposed by the `weakref` module for the benefit of advanced uses.

Not all objects can be weakly referenced. Objects which support weak references include class instances, functions written in Python (but not in C), instance methods, sets, frozensets, some `file objects`, `generators`, type objects, sockets, arrays, dequeues, regular expression pattern objects, and code objects.

*Changed in version 3.2:* Added support for `thread.lock`, `threading.Lock`, and code objects.

Several built-in types such as `list` and `dict` do not directly support weak references but can add support through subclassing:

```
class Dict(dict):  
    pass
```

```
obj = Dict(red=1, green=2, blue=3)    # this object is weakly
```

**CPython implementation detail:** Other built-in types such as `tuple` and `int` do not support weak references even when subclassed.

Extension types can easily be made to support weak references; see

## Weak Reference Support.

When `__slots__` are defined for a given type, weak reference support is disabled unless a `'__weakref__'` string is also present in the sequence of strings in the `__slots__` declaration. See [\\_slots\\_ documentation](#) for details.

`class weakref.ref(object[, callback])`

Return a weak reference to *object*. The original object can be retrieved by calling the reference object if the referent is still alive; if the referent is no longer alive, calling the reference object will cause **None** to be returned. If *callback* is provided and not **None**, and the returned weakref object is still alive, the callback will be called when the object is about to be finalized; the weak reference object will be passed as the only parameter to the callback; the referent will no longer be available.

It is allowable for many weak references to be constructed for the same object. Callbacks registered for each weak reference will be called from the most recently registered callback to the oldest registered callback.

Exceptions raised by the callback will be noted on the standard error output, but cannot be propagated; they are handled in exactly the same way as exceptions raised from an object's `__del__()` method.

Weak references are **hashable** if the *object* is hashable. They will maintain their hash value even after the *object* was deleted. If `hash()` is called the first time only after the *object* was deleted, the call will raise **TypeError**.

Weak references support tests for equality, but not ordering. If the referents are still alive, two references have the same equality relationship as their referents (regardless of the *callback*). If either referent has been deleted, the references are equal only if the reference objects are the same object.

This is a subclassable type rather than a factory function.

`_callback_`

This read-only attribute returns the callback currently associated to the weakref. If there is no callback or if the referent of the weakref is no longer alive then this attribute will have value `None`.

*Changed in version 3.4:* Added the `__callback__` attribute.

`weakref.proxy(object[, callback])`

Return a proxy to *object* which uses a weak reference. This supports use of the proxy in most contexts instead of requiring the explicit dereferencing used with weak reference objects. The returned object will have a type of either `ProxyType` or `CallableProxyType`, depending on whether *object* is callable. Proxy objects are not `hashable` regardless of the referent; this avoids a number of problems related to their fundamentally mutable nature, and prevents their use as dictionary keys. *callback* is the same as the parameter of the same name to the `ref()` function.

Accessing an attribute of the proxy object after the referent is garbage collected raises `ReferenceError`.

*Changed in version 3.8:* Extended the operator support on proxy objects to include the matrix multiplication operators `@` and `@=`.

`weakref.getweakrefcount(object)`

Return the number of weak references and proxies which refer to *object*.

`weakref.getweakrefs(object)`

Return a list of all weak reference and proxy objects which refer to *object*.

`class weakref.WeakKeyDictionary([dict])`

Mapping class that references keys weakly. Entries in the

dictionary will be discarded when there is no longer a strong reference to the key. This can be used to associate additional data with an object owned by other parts of an application without adding attributes to those objects. This can be especially useful with objects that override attribute accesses.

Note that when a key with equal value to an existing key (but not equal identity) is inserted into the dictionary, it replaces the value but does not replace the existing key. Due to this, when the reference to the original key is deleted, it also deletes the entry in the dictionary:

```
>>> class T(str): pass
...
>>> k1, k2 = T(), T()
>>> d = weakref.WeakKeyDictionary()
>>> d[k1] = 1      # d = {k1: 1}
>>> d[k2] = 2      # d = {k1: 2}
>>> del k1         # d = {}
```

A workaround would be to remove the key prior to reassignment:

```
>>> class T(str): pass
...
>>> k1, k2 = T(), T()
>>> d = weakref.WeakKeyDictionary()
>>> d[k1] = 1      # d = {k1: 1}
>>> del d[k1]
>>> d[k2] = 2      # d = {k2: 2}
>>> del k1         # d = {k2: 2}
```

*Changed in version 3.9:* Added support for `|` and `|=` operators, specified in [PEP 584](https://peps.python.org/pep-0584/) [https://peps.python.org/pep-0584/].

**WeakKeyDictionary** objects have an additional method that exposes the internal references directly. The references are not guaranteed to be “live” at the time they are used, so the result of calling the references needs to be checked before being used. This

can be used to avoid creating references that will cause the garbage collector to keep the keys around longer than needed.

`WeakKeyDictionary.keyrefs()`

Return an iterable of the weak references to the keys.

`class weakref.WeakValueDictionary([dict])`

Mapping class that references values weakly. Entries in the dictionary will be discarded when no strong reference to the value exists any more.

*Changed in version 3.9:* Added support for `|` and `|=` operators, as specified in [PEP 584](https://peps.python.org/pep-0584/) [https://peps.python.org/pep-0584/].

**WeakValueDictionary** objects have an additional method that has the same issues as the **keyrefs()** method of **WeakKeyDictionary** objects.

`WeakValueDictionary.valuerefs()`

Return an iterable of the weak references to the values.

`class weakref.WeakSet([elements])`

Set class that keeps weak references to its elements. An element will be discarded when no strong reference to it exists any more.

`class weakref.WeakMethod(method[, callback])`

A custom **ref** subclass which simulates a weak reference to a bound method (i.e., a method defined on a class and looked up on an instance). Since a bound method is ephemeral, a standard weak reference cannot keep hold of it.

**WeakMethod** has special code to recreate the bound method until either the object or the original function dies:

```
>>> class C:
...     def method(self):
...         print("method called!")
```

```

...
>>> c = C()
>>> r = weakref.ref(c.method)
>>> r()
>>> r = weakref.WeakMethod(c.method)
>>> r()
<bound method C.method of <__main__.C object at 0x7
>>> r() ()
method called!
>>> del c
>>> gc.collect()
0
>>> r()
>>>

```

*callback* is the same as the parameter of the same name to the `ref()` function.

*New in version 3.4.*

`class weakref.finalize(obj, func, /, *args, **kwargs)`

Return a callable finalizer object which will be called when *obj* is garbage collected. Unlike an ordinary weak reference, a finalizer will always survive until the reference object is collected, greatly simplifying lifecycle management.

A finalizer is considered *alive* until it is called (either explicitly or at garbage collection), and after that it is *dead*. Calling a live finalizer returns the result of evaluating `func(*arg, **kwargs)`, whereas calling a dead finalizer returns `None`.

Exceptions raised by finalizer callbacks during garbage collection will be shown on the standard error output, but cannot be propagated. They are handled in the same way as exceptions raised from an object's `__del__()` method or a weak reference's callback.

When the program exits, each remaining live finalizer is called unless its `atexit` attribute has been set to false. They

are called in reverse order of creation.

A finalizer will never invoke its callback during the later part of the [interpreter shutdown](#) when module globals are liable to have been replaced by **None**.

`_call_()`

If *self* is alive then mark it as dead and return the result of calling `func(*args, **kwargs)`. If *self* is dead then return **None**.

`detach()`

If *self* is alive then mark it as dead and return the tuple `(obj, func, args, kwargs)`. If *self* is dead then return **None**.

`peek()`

If *self* is alive then return the tuple `(obj, func, args, kwargs)`. If *self* is dead then return **None**.

`alive`

Property which is true if the finalizer is alive, false otherwise.

`atexit`

A writable boolean property which by default is true. When the program exits, it calls all remaining live finalizers for which **atexit** is true. They are called in reverse order of creation.

## Note

It is important to ensure that *func*, *args* and *kwargs* do not own any references to *obj*, either directly or indirectly, since otherwise *obj* will never be garbage collected. In particular, *func* should not be a bound method of *obj*.

*New in version 3.4.*

`weakref.ReferenceType`

The type object for weak references objects.

`weakref.ProxyType`

The type object for proxies of objects which are not callable.

`weakref.CallableProxyType`

The type object for proxies of callable objects.

`weakref.ProxyTypes`

Sequence containing all the type objects for proxies. This can make it simpler to test if an object is a proxy without being dependent on naming both proxy types.

### See also

**PEP 205** [<https://peps.python.org/pep-0205/>] - **Weak References**

The proposal and rationale for this feature, including links to earlier implementations and information about similar features in other languages.

## Weak Reference Objects

Weak reference objects have no methods and no attributes besides `ref.__callback__`. A weak reference object allows the referent to be obtained, if it still exists, by calling it:

```
>>> import weakref
>>> class Object:
...     pass
...
>>> o = Object()
>>> r = weakref.ref(o)
>>> o2 = r()
>>> o is o2
True
```

If the referent no longer exists, calling the reference object returns **None**:

```
>>> del o, o2
>>> print(r())
None
```

Testing that a weak reference object is still live should be done using the expression `ref()` is not `None`. Normally, application code that needs to use a reference object should follow this pattern:

```
# r is a weak reference object
o = r()
if o is None:
    # referent has been garbage collected
    print("Object has been deallocated; can't frobnicate")
else:
    print("Object is still live!")
    o.do_something_useful()
```

Using a separate test for “liveness” creates race conditions in threaded applications; another thread can cause a weak reference to become invalidated before the weak reference is called; the idiom shown above is safe in threaded applications as well as single-threaded applications.

Specialized versions of **ref** objects can be created through subclassing. This is used in the implementation of the **WeakValueDictionary** to reduce the memory overhead for each entry in the mapping. This may be most useful to associate additional information with a reference, but could also be used to insert additional processing on calls to retrieve the referent.

This example shows how a subclass of **ref** can be used to store additional information about an object and affect the value that’s returned when the referent is accessed:

```
import weakref

class ExtendedRef(weakref.ref):
```

```

def __init__(self, ob, callback=None, /, **annotations):
    super().__init__(ob, callback)
    self.__counter = 0
    for k, v in annotations.items():
        setattr(self, k, v)

def __call__(self):
    """Return a pair containing the referent and the
    times the reference has been called.
    """
    ob = super().__call__()
    if ob is not None:
        self.__counter += 1
        ob = (ob, self.__counter)
    return ob

```

## Example

This simple example shows how an application can use object IDs to retrieve objects that it has seen before. The IDs of the objects can then be used in other data structures without forcing the objects to remain alive, but the objects can still be retrieved by ID if they do.

```

import weakref

_id2obj_dict = weakref.WeakValueDictionary()

def remember(obj):
    oid = id(obj)
    _id2obj_dict[oid] = obj
    return oid

def id2obj(oid):
    return _id2obj_dict[oid]

```

## Finalizer Objects

The main benefit of using **finalize** is that it makes it simple to

register a callback without needing to preserve the returned finalizer object. For instance

```
>>> import weakref
>>> class Object:
...     pass
...
>>> kenny = Object()
>>> weakref.finalize(kenny, print, "You killed Kenny!")
<finalize object at ...; for 'Object' at ...>
>>> del kenny
You killed Kenny!
```

The finalizer can be called directly as well. However the finalizer will invoke the callback at most once.

```
>>> def callback(x, y, z):
...     print("CALLBACK")
...     return x + y + z
...
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> assert f.alive
>>> assert f() == 6
CALLBACK
>>> assert not f.alive
>>> f()                                # callback not called because
>>> del obj                             # callback not called because
```

You can unregister a finalizer using its `detach()` method. This kills the finalizer and returns the arguments passed to the constructor when it was created.

```
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> f.detach()
(<...Object object ...>, <function callback ...>, (1, 2))
>>> newobj, func, args, kwargs = _
>>> assert not f.alive
>>> assert newobj is obj
```

```
>>> assert func(*args, **kwargs) == 6
CALLBACK
```

Unless you set the `atexit` attribute to `False`, a finalizer will be called when the program exits if it is still alive. For instance

```
>>> obj = Object()
>>> weakref.finalize(obj, print, "obj dead or exiting")
<finalize object at ...; for 'Object' at ...>
>>> exit()
obj dead or exiting
```

## Comparing finalizers with `__del__()` methods

Suppose we want to create a class whose instances represent temporary directories. The directories should be deleted with their contents when the first of the following events occurs:

- the object is garbage collected,
- the object's `remove()` method is called, or
- the program exits.

We might try to implement the class using a `__del__()` method as follows:

```
class TempDir:
    def __init__(self):
        self.name = tempfile.mkdtemp()

    def remove(self):
        if self.name is not None:
            shutil.rmtree(self.name)
            self.name = None

    @property
    def removed(self):
        return self.name is None
```

```
def __del__(self):  
    self.remove()
```

Starting with Python 3.4, `__del__()` methods no longer prevent reference cycles from being garbage collected, and module globals are no longer forced to `None` during [interpreter shutdown](#). So this code should work without any issues on CPython.

However, handling of `__del__()` methods is notoriously implementation specific, since it depends on internal details of the interpreter's garbage collector implementation.

A more robust alternative can be to define a finalizer which only references the specific functions and objects that it needs, rather than having access to the full state of the object:

```
class TempDir:  
    def __init__(self):  
        self.name = tempfile.mkdtemp()  
        self._finalizer = weakref.finalize(self, shutil.rmtree,  
   self.name)  
  
    def remove(self):  
        self._finalizer()   
  
    @property  
    def removed(self):  
        return not self._finalizer.alive
```

Defined like this, our finalizer only receives a reference to the details it needs to clean up the directory appropriately. If the object never gets garbage collected the finalizer will still be called at exit.

The other advantage of weakref based finalizers is that they can be used to register finalizers for classes where the definition is controlled by a third party, such as running code when a module is unloaded:

```
import weakref, sys  
def unloading_module():  
    # implicit reference to the module globals from the
```

```
weakref.finalize(sys.modules[__name__], unloading_module)
```

## Note

If you create a finalizer object in a daemon thread just as the program exits then there is the possibility that the finalizer does not get called at exit. However, in a daemon thread `atexit.register()`, `try: ... finally: ...` and `with: ...` do not guarantee that cleanup occurs either.

# types — Dynamic type creation and names for built-in types

**Source code:** [Lib/types.py](https://github.com/python/cpython/tree/3.11/Lib/types.py) [https://github.com/python/cpython/tree/3.11/Lib/types.py]

---

This module defines utility functions to assist in dynamic creation of new types.

It also defines names for some object types that are used by the standard Python interpreter, but not exposed as builtins like `int` or `str` are.

Finally, it provides some additional type-related utility classes and functions that are not fundamental enough to be builtins.

## Dynamic Type Creation

`types.new_class(name, bases = (), kwds = None, exec_body = None)`

Creates a class object dynamically using the appropriate metaclass.

The first three arguments are the components that make up a class definition header: the class name, the base classes (in order), the keyword arguments (such as `metaclass`).

The `exec_body` argument is a callback that is used to populate the freshly created class namespace. It should accept the class namespace as its sole argument and update the namespace directly with the class contents. If no callback is provided, it has the same effect as passing in `lambda ns: None`.

*New in version 3.3.*

`types.prepare_class(name, bases = (), kwds = None)`

Calculates the appropriate metaclass and creates the class namespace.

The arguments are the components that make up a class definition header: the class name, the base classes (in order) and the keyword arguments (such as `metaclass`).

The return value is a 3-tuple: `metaclass`, `namespace`, `kwds`

*metaclass* is the appropriate metaclass, *namespace* is the prepared class namespace and *kwds* is an updated copy of the passed in *kwds* argument with any `'metaclass'` entry removed. If no *kwds* argument is passed in, this will be an empty dict.

*New in version 3.3.*

*Changed in version 3.6:* The default value for the `namespace` element of the returned tuple has changed. Now an insertion-order-preserving mapping is used when the metaclass does not have a `__prepare__` method.

**See also**

## Metaclasses

Full details of the class creation process supported by these functions

**PEP 3115** [<https://peps.python.org/pep-3115/>] - **Metaclasses in Python 3000**

Introduced the `__prepare__` namespace hook

`types.resolve_bases(bases)`

Resolve MRO entries dynamically as specified by **PEP 560** [<https://peps.python.org/pep-0560/>].

This function looks for items in *bases* that are not instances of `type`, and returns a tuple where each such object that has an `__mro_entries__()` method is replaced with an unpacked result of calling this method. If a *bases* item is an instance of `type`, or it doesn't have an `__mro_entries__()` method, then it is included in the return tuple unchanged.

*New in version 3.7.*

**PEP 560** [<https://peps.python.org/pep-0560/>] - Core support for typing module and generic types

# Standard Interpreter Types

This module provides names for many of the types that are required to implement a Python interpreter. It deliberately avoids including some of the types that arise only incidentally during processing such as the `listiterator` type.

Typical use of these names is for `isinstance()` or `issubclass()` checks.

If you instantiate any of these types, note that signatures may vary between Python versions.

Standard names are defined for the following types:

`types.NoneType`

The type of `None`.

*New in version 3.10.*

`types.FunctionType`

`types.LambdaType`

The type of user-defined functions and functions created by `lambda` expressions.

Raises an [auditing event](#) `function.__new__` with argument `code`.

The audit event only occurs for direct instantiation of function objects, and is not raised for normal compilation.

#### `types.GeneratorType`

The type of [generator](#)-iterator objects, created by generator functions.

#### `types.CoroutineType`

The type of [coroutine](#) objects, created by [async def](#) functions.

*New in version 3.5.*

#### `types.AsyncGeneratorType`

The type of [asynchronous generator](#)-iterator objects, created by asynchronous generator functions.

*New in version 3.6.*

#### `class types.CodeType(**kwargs)`

The type for code objects such as returned by [compile\(\)](#).

Raises an [auditing event](#) `code.__new__` with arguments `code`, `filename`, `name`, `argcount`, `posonlyargcount`, `kwnonlyargcount`, `nlocals`, `stacksize`, `flags`.

Note that the audited arguments may not match the names or positions required by the initializer. The audit event only occurs for direct instantiation of code objects, and is not raised for normal compilation.

#### `replace(**kwargs)`

Return a copy of the code object with new values for the specified fields.

*New in version 3.8.*

types.CellType

The type for cell objects: such objects are used as containers for a function's free variables.

*New in version 3.8.*

types.MethodType

The type of methods of user-defined class instances.

types.BuiltinFunctionType

types.BuiltinMethodType

The type of built-in functions like `len()` or `sys.exit()`, and methods of built-in classes. (Here, the term “built-in” means “written in C”.)

types.WrapperDescriptorType

The type of methods of some built-in data types and base classes such as `object.__init__()` or `object.__lt__()`.

*New in version 3.7.*

types.MethodWrapperType

The type of *bound* methods of some built-in data types and base classes. For example it is the type of `object().__str__`.

*New in version 3.7.*

types.NotImplementedType

The type of `NotImplemented`.

*New in version 3.10.*

types.MethodDescriptorType

The type of methods of some built-in data types such as `str.join()`.

*New in version 3.7.*

`types.ClassMethodDescriptorType`

The type of *unbound* class methods of some built-in data types such as `dict.__dict__['fromkeys']`.

*New in version 3.7.*

*class* `types.ModuleType(name, doc = None)`

The type of [modules](#). The constructor takes the name of the module to be created and optionally its [docstring](#).

### Note

Use [importlib.util.module\\_from\\_spec\(\)](#) to create a new module if you wish to set the various import-controlled attributes.

`__doc__`

The [docstring](#) of the module. Defaults to `None`.

`__loader__`

The [loader](#) which loaded the module. Defaults to `None`.

This attribute is to match

[importlib.machinery.ModuleSpec.loader](#) as stored in the `__spec__` object.

### Note

A future version of Python may stop setting this attribute by default. To guard against this potential change, preferably read from the `__spec__` attribute instead or use `getattr(module, "__loader__", None)` if you explicitly need to use this attribute.

*Changed in version 3.4:* Defaults to `None`. Previously the

attribute was optional.

`__name__`

The name of the module. Expected to match `importlib.machinery.ModuleSpec.name`.

`__package__`

Which `package` a module belongs to. If the module is top-level (i.e. not a part of any specific package) then the attribute should be set to `'`, else it should be set to the name of the package (which can be `__name__` if the module is a package itself). Defaults to `None`.

This attribute is to match `importlib.machinery.ModuleSpec.parent` as stored in the `__spec__` object.

### Note

A future version of Python may stop setting this attribute by default. To guard against this potential change, preferably read from the `__spec__` attribute instead or use `getattr(module, "__package__", None)` if you explicitly need to use this attribute.

*Changed in version 3.4:* Defaults to `None`. Previously the attribute was optional.

`__spec__`

A record of the module's import-system-related state. Expected to be an instance of `importlib.machinery.ModuleSpec`.

*New in version 3.4.*

`types.EllipsisType`

The type of `Ellipsis`.

*New in version 3.10.*

*class* `types.GenericAlias(t_origin, t_args)`

The type of [parameterized generics](#) such as `list[int]`.

*t\_origin* should be a non-parameterized generic class, such as `list`, `tuple` or `dict`. *t\_args* should be a [tuple](#) (possibly of length 1) of types which parameterize *t\_origin*:

```
>>> from types import GenericAlias

>>> list[int] == GenericAlias(list, (int,))
True
>>> dict[str, int] == GenericAlias(dict, (str, int))
True
```

*New in version 3.9.*

*Changed in version 3.9.2:* This type can now be subclassed.

**See also**

### [Generic Alias Types](#)

In-depth documentation on instances of `types.GenericAlias`

### [PEP 585](https://peps.python.org/pep-0585/) [https://peps.python.org/pep-0585/] - Type Hinting Generics In Standard Collections

Introducing the `types.GenericAlias` class

*class* `types.UnionType`

The type of [union type expressions](#).

*New in version 3.10.*

*class* `types.TracebackType(tb_next, tb_frame, tb_lasti, tb_lineno)`

The type of traceback objects such as found in

```
sys.exception().__traceback__.
```

See [the language reference](#) for details of the available attributes and operations, and guidance on creating tracebacks dynamically.

### `types.FrameType`

The type of frame objects such as found in `tb.tb_frame` if `tb` is a traceback object.

See [the language reference](#) for details of the available attributes and operations.

### `types.GetSetDescriptorType`

The type of objects defined in extension modules with `PyGetSetDef`, such as `FrameType.f_locals` or `array.array.typecode`. This type is used as descriptor for object attributes; it has the same purpose as the [property](#) type, but for classes defined in extension modules.

### `types.MemberDescriptorType`

The type of objects defined in extension modules with `PyMemberDef`, such as `datetime.timedelta.days`. This type is used as descriptor for simple C data members which use standard conversion functions; it has the same purpose as the [property](#) type, but for classes defined in extension modules.

**CPython implementation detail:** In other implementations of Python, this type may be identical to `GetSetDescriptorType`.

### *class* `types.MappingProxyType(mapping)`

Read-only proxy of a mapping. It provides a dynamic view on the mapping's entries, which means that when the mapping changes, the view reflects these changes.

*New in version 3.3.*

*Changed in version 3.9:* Updated to support the new union (`|`) operator from [PEP 584](https://peps.python.org/pep-0584/) [https://peps.python.org/pep-0584/], which simply delegates to the underlying mapping.

`key in proxy`

Return `True` if the underlying mapping has a key *key*, else `False`.

`proxy[key]`

Return the item of the underlying mapping with key *key*. Raises a `KeyError` if *key* is not in the underlying mapping.

`iter(proxy)`

Return an iterator over the keys of the underlying mapping. This is a shortcut for `iter(proxy.keys())`.

`len(proxy)`

Return the number of items in the underlying mapping.

`copy()`

Return a shallow copy of the underlying mapping.

`get(key[, default])`

Return the value for *key* if *key* is in the underlying mapping, else *default*. If *default* is not given, it defaults to `None`, so that this method never raises a `KeyError`.

`items()`

Return a new view of the underlying mapping's items (`((key, value) pairs)`).

`keys()`

Return a new view of the underlying mapping's keys.

`values()`

Return a new view of the underlying mapping's values.

`reversed(proxy)`

Return a reverse iterator over the keys of the underlying mapping.

*New in version 3.9.*

## Additional Utility Classes and Functions

*class* `types.SimpleNamespace`

A simple **object** subclass that provides attribute access to its namespace, as well as a meaningful repr.

Unlike **object**, with `SimpleNamespace` you can add and remove attributes. If a `SimpleNamespace` object is initialized with keyword arguments, those are directly added to the underlying namespace.

The type is roughly equivalent to the following code:

```
class SimpleNamespace:
    def __init__(self, /, **kwargs):
        self.__dict__.update(kwargs)

    def __repr__(self):
        items = (f"{k}={v!r}" for k, v in self.__dict__.items())
        return "{}({})".format(type(self).__name__, items)

    def __eq__(self, other):
        if isinstance(self, SimpleNamespace) and isinstance(other, SimpleNamespace):
            return self.__dict__ == other.__dict__
        return NotImplemented
```

`SimpleNamespace` may be useful as a replacement for `class NS: pass`. However, for a structured record type use **`namedtuple()`** instead.

*New in version 3.3.*

*Changed in version 3.9:* Attribute order in the repr changed from alphabetical to insertion (like `dict`).

`types.DynamicClassAttribute(fget=None, fset=None, fdel=None, doc=None)`

Route attribute access on a class to `__getattr__`.

This is a descriptor, used to define attributes that act differently when accessed through an instance and through a class. Instance access remains normal, but access to an attribute through a class will be routed to the class's `__getattr__` method; this is done by raising `AttributeError`.

This allows one to have properties active on an instance, and have virtual attributes on the class with the same name (see [enum.Enum](#) for an example).

*New in version 3.4.*

## Coroutine Utility Functions

`types.coroutine(gen_func)`

This function transforms a [generator](#) function into a [coroutine function](#) which returns a generator-based coroutine. The generator-based coroutine is still a [generator iterator](#), but is also considered to be a [coroutine](#) object and is [awaitable](#). However, it may not necessarily implement the `__await__()` method.

If `gen_func` is a generator function, it will be modified in-place.

If `gen_func` is not a generator function, it will be wrapped. If it returns an instance of `collections.abc.Generator`, the instance will be wrapped in an *awaitable* proxy object. All other types of objects will be returned as is.

*New in version 3.5.*

# copy — Shallow and deep copy operations

**Source code:** [Lib/copy.py](https://github.com/python/cpython/tree/3.11/Lib/copy.py) [https://github.com/python/cpython/tree/3.11/Lib/copy.py]

---

Assignment statements in Python do not copy objects, they create bindings between a target and an object. For collections that are mutable or contain mutable items, a copy is sometimes needed so one can change one copy without changing the other. This module provides generic shallow and deep copy operations (explained below).

Interface summary:

`copy.copy(x)`

Return a shallow copy of *x*.

`copy.deepcopy(x[, memo])`

Return a deep copy of *x*.

*exception* `copy.Error`

Raised for module specific errors.

The difference between shallow and deep copying is only relevant for compound objects (objects that contain other objects, like lists or class instances):

- A *shallow copy* constructs a new compound object and then (to the extent possible) inserts *references* into it to the objects found in the original.
- A *deep copy* constructs a new compound object and then, recursively, inserts *copies* into it of the objects found in the

original.

Two problems often exist with deep copy operations that don't exist with shallow copy operations:

- Recursive objects (compound objects that, directly or indirectly, contain a reference to themselves) may cause a recursive loop.
- Because deep copy copies everything it may copy too much, such as data which is intended to be shared between copies.

The `deepcopy()` function avoids these problems by:

- keeping a `memo` dictionary of objects already copied during the current copying pass; and
- letting user-defined classes override the copying operation or the set of components copied.

This module does not copy types like module, method, stack trace, stack frame, file, socket, window, or any similar types. It does “copy” functions and classes (shallow and deeply), by returning the original object unchanged; this is compatible with the way these are treated by the `pickle` module.

Shallow copies of dictionaries can be made using `dict.copy()`, and of lists by assigning a slice of the entire list, for example, `copied_list = original_list[:]`.

Classes can use the same interfaces to control copying that they use to control pickling. See the description of module `pickle` for information on these methods. In fact, the `copy` module uses the registered pickle functions from the `copyreg` module.

In order for a class to define its own copy implementation, it can define special methods `__copy__()` and `__deepcopy__()`. The former is called to implement the shallow copy operation; no additional arguments are passed. The latter is called to implement the deep copy operation; it is passed one argument, the `memo` dictionary. If the `__deepcopy__()` implementation needs to make a deep copy of a component, it should call the `deepcopy()` function with the component as first argument and the `memo`

dictionary as second argument. The memo dictionary should be treated as an opaque object.

# `pprint` — Data pretty printer

**Source code:** [Lib/pprint.py](#) [<https://github.com/python/cpython/tree/3.11/Lib/pprint.py>]

---

The `pprint` module provides a capability to “pretty-print” arbitrary Python data structures in a form which can be used as input to the interpreter. If the formatted structures include objects which are not fundamental Python types, the representation may not be loadable. This may be the case if objects such as files, sockets or classes are included, as well as many other objects which are not representable as Python literals.

The formatted representation keeps objects on a single line if it can, and breaks them onto multiple lines if they don’t fit within the allowed width. Construct `PrettyPrinter` objects explicitly if you need to adjust the width constraint.

Dictionaries are sorted by key before the display is computed.

*Changed in version 3.9:* Added support for pretty-printing `types.SimpleNamespace`.

*Changed in version 3.10:* Added support for pretty-printing `dataclasses.dataclass`.

The `pprint` module defines one class:

```
class pprint.PrettyPrinter(indent=1, width=80, depth=None,
stream=None, *, compact=False, sort_dicts=True,
underscore_numbers=False)
```

Construct a `PrettyPrinter` instance. This constructor understands several keyword parameters.

`stream` (default `sys.stdout`) is a [file-like object](#) to which the output will be written by calling its `write()` method. If

both *stream* and `sys.stdout` are `None`, then `pprint()` silently returns.

Other values configure the manner in which nesting of complex data structures is displayed.

*indent* (default 1) specifies the amount of indentation added for each nesting level.

*depth* controls the number of nesting levels which may be printed; if the data structure being printed is too deep, the next contained level is replaced by `. . .`. By default, there is no constraint on the depth of the objects being formatted.

*width* (default 80) specifies the desired maximum number of characters per line in the output. If a structure cannot be formatted within the width constraint, a best effort will be made.

*compact* impacts the way that long sequences (lists, tuples, sets, etc) are formatted. If *compact* is false (the default) then each item of a sequence will be formatted on a separate line. If *compact* is true, as many items as will fit within the *width* will be formatted on each output line.

If *sort\_dicts* is true (the default), dictionaries will be formatted with their keys sorted, otherwise they will display in insertion order.

If *underscore\_numbers* is true, integers will be formatted with the `_` character for a thousands separator, otherwise underscores are not displayed (the default).

*Changed in version 3.4:* Added the *compact* parameter.

*Changed in version 3.8:* Added the *sort\_dicts* parameter.

*Changed in version 3.10:* Added the *underscore\_numbers* parameter.

*Changed in version 3.11:* No longer attempts to write to `sys.stdout` if it is `None`.

```

>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights']
>>> stuff.insert(0, stuff[:])
>>> pp = pprint.PrettyPrinter(indent=4)
>>> pp.pprint(stuff)
[ ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
  'spam',
  'eggs',
  'lumberjack',
  'knights',
  'ni']
>>> pp = pprint.PrettyPrinter(width=41, compact=True)
>>> pp.pprint(stuff)
[['spam', 'eggs', 'lumberjack',
  'knights', 'ni'],
 'spam', 'eggs', 'lumberjack', 'knights',
 'ni']
>>> tup = ('spam', ('eggs', ('lumberjack', ('knights', ('ni',
... ('parrot', ('fresh fruit',)))))))
>>> pp = pprint.PrettyPrinter(depth=6)
>>> pp.pprint(tup)
('spam', ('eggs', ('lumberjack', ('knights', ('ni',

```

`pprint.pformat(object, indent=1, width=80, depth=None, *, compact=False, sort_dicts=True, underscore_numbers=False)`

Return the formatted representation of *object* as a string. *indent*, *width*, *depth*, *compact*, *sort\_dicts* and *underscore\_numbers* are passed to the [PrettyPrinter](#) constructor as formatting parameters and their meanings are as described in its documentation above.

`pprint.pp(object, *args, sort_dicts=False, **kwargs)`

Prints the formatted representation of *object* followed by a newline. If *sort\_dicts* is false (the default), dictionaries will be displayed with their keys in insertion order, otherwise the dict keys will be sorted. *args* and *kwargs* will be passed to [pprint\(\)](#) as formatting parameters.

*New in version 3.8.*

`pprint.pprint(object, stream=None, indent=1, width=80,  
depth=None, *, compact=False, sort_dicts=True,  
underscore_numbers=False)`

Prints the formatted representation of *object* on *stream*, followed by a newline. If *stream* is `None`, `sys.stdout` is used. This may be used in the interactive interpreter instead of the `print()` function for inspecting values (you can even reassign `print = pprint.pprint` for use within a scope).

The configuration parameters *stream*, *indent*, *width*, *depth*, *compact*, *sort\_dicts* and *underscore\_numbers* are passed to the `PrettyPrinter` constructor and their meanings are as described in its documentation above.

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights']
>>> stuff.insert(0, stuff)
>>> pprint.pprint(stuff)
[<Recursion on list with id=...>,
 'spam',
 'eggs',
 'lumberjack',
 'knights',
 'ni']
```

`pprint.isreadable(object)`

Determine if the formatted representation of *object* is “readable”, or can be used to reconstruct the value using `eval()`. This always returns `False` for recursive objects.

```
>>> pprint.isreadable(stuff)
False
```

`pprint.isrecursive(object)`

Determine if *object* requires a recursive representation.

One more support function is also defined:

`pprint.saferepr(object)`

Return a string representation of *object*, protected against recursive data structures. If the representation of *object* exposes a recursive entry, the recursive reference will be represented as `<Recursion on typename with id=number>`. The representation is not otherwise formatted.

```
>>> pprint.saferepr(stuff)
" [<Recursion on list with id=...>, 'spam', 'eggs',
```

## PrettyPrinter Objects

**PrettyPrinter** instances have the following methods:

`PrettyPrinter.pformat(object)`

Return the formatted representation of *object*. This takes into account the options passed to the **PrettyPrinter** constructor.

`PrettyPrinter.pprint(object)`

Print the formatted representation of *object* on the configured stream, followed by a newline.

The following methods provide the implementations for the corresponding functions of the same names. Using these methods on an instance is slightly more efficient since new **PrettyPrinter** objects don't need to be created.

`PrettyPrinter.isreadable(object)`

Determine if the formatted representation of the object is "readable," or can be used to reconstruct the value using `eval()`. Note that this returns `False` for recursive objects. If the *depth* parameter of the **PrettyPrinter** is set and the object is deeper than allowed, this returns `False`.

`PrettyPrinter.isrecursive(object)`

Determine if the object requires a recursive representation.

This method is provided as a hook to allow subclasses to modify the way objects are converted to strings. The default implementation uses the internals of the `saferepr()` implementation.

`PrettyPrinter.format(object, context, maxlevels, level)`

Returns three values: the formatted version of *object* as a string, a flag indicating whether the result is readable, and a flag indicating whether recursion was detected. The first argument is the object to be presented. The second is a dictionary which contains the `id()` of objects that are part of the current presentation context (direct and indirect containers for *object* that are affecting the presentation) as the keys; if an object needs to be presented which is already represented in *context*, the third return value should be `True`. Recursive calls to the `format()` method should add additional entries for containers to this dictionary. The third argument, *maxlevels*, gives the requested limit to recursion; this will be `0` if there is no requested limit. This argument should be passed unmodified to recursive calls. The fourth argument, *level*, gives the current level; recursive calls should be passed a value less than that of the current call.

## Example

To demonstrate several uses of the `pprint()` function and its parameters, let's fetch information about a project from [PyPI](https://pypi.org) [https://pypi.org]:

```
>>> import json
>>> import pprint
>>> from urllib.request import urlopen
>>> with urlopen('https://pypi.org/pypi/sampleproject/json') as resp:
...     project_info = json.load(resp)['info']
```

In its basic form, `pprint()` shows the whole object:

```
>>> pprint.pprint(project_info)
```

```

# reprlib — Alternate repr() implementation

**Source code:** [Lib/reprlib.py](https://github.com/python/cpython/tree/3.11/Lib/reprlib.py) [https://github.com/python/cpython/tree/3.11/Lib/reprlib.py]

---

The `reprlib` module provides a means for producing object representations with limits on the size of the resulting strings. This is used in the Python debugger and may be useful in other contexts as well.

This module provides a class, an instance, and a function:

`class reprlib.Repr`

Class which provides formatting services useful in implementing functions similar to the built-in `repr()`; size limits for different object types are added to avoid the generation of representations which are excessively long.

`reprlib.aRepr`

This is an instance of `Repr` which is used to provide the `repr()` function described below. Changing the attributes of this object will affect the size limits used by `repr()` and the Python debugger.

`reprlib.repr(obj)`

This is the `repr()` method of `aRepr`. It returns a string similar to that returned by the built-in function of the same name, but with limits on most sizes.

In addition to size-limiting tools, the module also provides a decorator for detecting recursive calls to `__repr__()` and substituting a placeholder string instead.

`@reprlib.recursive_repr(fillvalue='...')`

Decorator for `__repr__()` methods to detect recursive calls within the same thread. If a recursive call is made, the *fillvalue* is returned, otherwise, the usual `__repr__()` call is made. For example:

```
>>> from reprlib import recursive_repr
>>> class MyList(list):
...     @recursive_repr()
...     def __repr__(self):
...         return '<' + '|' .join(map(repr, self))
...
>>> m = MyList('abc')
>>> m.append(m)
>>> m.append('x')
>>> print(m)
<'a'|'b'|'c'|...|'x'>
```

*New in version 3.2.*

## Repr Objects

**Repr** instances provide several attributes which can be used to provide size limits for the representations of different object types, and methods which format specific object types.

**Repr.fillvalue**

This string is displayed for recursive references. It defaults to `...`

*New in version 3.11.*

**Repr.maxlevel**

Depth limit on the creation of recursive representations. The default is 6.

**Repr.maxdict**

**Repr.maxlist**

Repr.maxtuple  
Repr.maxset  
Repr.maxfrozenset  
Repr.maxdeque  
Repr.maxarray

Limits on the number of entries represented for the named object type. The default is 4 for `maxdict`, 5 for `maxarray`, and 6 for the others.

Repr.maxlong

Maximum number of characters in the representation for an integer. Digits are dropped from the middle. The default is 40.

Repr.maxstring

Limit on the number of characters in the representation of the string. Note that the “normal” representation of the string is used as the character source: if escape sequences are needed in the representation, these may be mangled when the representation is shortened. The default is 30.

Repr.maxother

This limit is used to control the size of object types for which no specific formatting method is available on the `Repr` object. It is applied in a similar manner as `maxstring`. The default is 20.

Repr.repr(*obj*)

The equivalent to the built-in `repr()` that uses the formatting imposed by the instance.

Repr.repr1(*obj*, *level*)

Recursive implementation used by `repr()`. This uses the type of *obj* to determine which formatting method to call, passing it *obj* and *level*. The type-specific methods should call `repr1()` to perform recursive formatting, with `level - 1` for the value of *level* in the recursive call.

`Repr.repr_TYPE(obj, level)`

Formatting methods for specific types are implemented as methods with a name based on the type name. In the method name, **TYPE** is replaced by

`'_'.join(type(obj).__name__.split())`. Dispatch to these methods is handled by `repr1()`. Type-specific methods which need to recursively format a value should call `self.repr1(subobj, level - 1)`.

## Subclassing Repr Objects

The use of dynamic dispatching by `Repr.repr1()` allows subclasses of `Repr` to add support for additional built-in object types or to modify the handling of types already supported. This example shows how special support for file objects could be added:

```
import reprlib
import sys
```

```
class MyRepr(reprlib.Repr):
```

```
    def repr_TextIOWrapper(self, obj, level):
        if obj.name in {'<stdin>', '<stdout>', '<stderr>'}:
            return obj.name
        return repr(obj)
```

```
aRepr = MyRepr()
```

```
print(aRepr.repr(sys.stdin))           # prints '<stdin>'
```

# enum — Support for enumerations

*New in version 3.4.*

**Source code:** [Lib/enum.py](https://github.com/python/cpython/tree/3.11/Lib/enum.py) [https://github.com/python/cpython/tree/3.11/Lib/enum.py]

## Important

This page contains the API reference information. For tutorial information and discussion of more advanced topics, see

- [Basic Tutorial](#)
- [Advanced Tutorial](#)
- [Enum Cookbook](#)

---

An enumeration:

- is a set of symbolic names (members) bound to unique values
- can be iterated over to return its canonical (i.e. non-alias) members in definition order
- uses *call* syntax to return members by value
- uses *index* syntax to return members by name

Enumerations are created either by using **class** syntax, or by using function-call syntax:

```
>>> from enum import Enum

>>> # class syntax
>>> class Color(Enum):
...     RED = 1
...     GREEN = 2
...     BLUE = 3
```

```
>>> # functional syntax
>>> Color = Enum('Color', ['RED', 'GREEN', 'BLUE'])
```

Even though we can use **class** syntax to create Enums, Enums are not normal Python classes. See [How are Enums different?](#) for more details.

## Note

### Nomenclature

- The class **Color** is an *enumeration* (or *enum*)
- The attributes **Color.RED**, **Color.GREEN**, etc., are *enumeration members* (or *members*) and are functionally constants.
- The enum members have *names* and *values* (the name of **Color.RED** is `RED`, the value of **Color.BLUE** is `3`, etc.)

---

# Module Contents

## EnumType

The `type` for Enum and its subclasses.

## Enum

Base class for creating enumerated constants.

## IntEnum

Base class for creating enumerated constants that are also subclasses of `int`. ([Notes](#))

## StrEnum

Base class for creating enumerated constants that are also subclasses of `str`. (Notes)

## Flag

Base class for creating enumerated constants that can be combined using the bitwise operations without losing their `Flag` membership.

## IntFlag

Base class for creating enumerated constants that can be combined using the bitwise operators without losing their `IntFlag` membership. `IntFlag` members are also subclasses of `int`. (Notes)

## ReprEnum

Used by `IntEnum`, `StrEnum`, and `IntFlag` to keep the `str()` of the mixed-in type.

## EnumCheck

An enumeration with the values `CONTINUOUS`, `NAMED_FLAGS`, and `UNIQUE`, for use with `verify()` to ensure various constraints are met by a given enumeration.

## FlagBoundary

An enumeration with the values `STRICT`, `CONFORM`, `EJECT`, and `KEEP` which allows for more fine-grained control over how invalid values are dealt with in an

enumeration.

### `auto`

Instances are replaced with an appropriate value for Enum members. `StrEnum` defaults to the lower-cased version of the member name, while other Enums default to 1 and increase from there.

### `property()`

Allows `Enum` members to have attributes without conflicting with member names.

### `unique()`

Enum class decorator that ensures only one name is bound to any one value.

### `verify()`

Enum class decorator that checks user-selectable constraints on an enumeration.

### `member()`

Make `obj` a member. Can be used as a decorator.

### `nonmember()`

Do not make `obj` a member. Can be used as a decorator.

### `global_enum()`

Modify the `str()` and `repr()` of

an enum to show its members as belonging to the module instead of its class, and export the enum members to the global namespace.

`show_flag_values()`

Return a list of all power-of-two integers contained in a flag.

*New in version 3.6:* `Flag`, `IntFlag`, `auto`

*New in version 3.11:* `StrEnum`, `EnumCheck`, `ReprEnum`, `FlagBoundary`, `property`, `member`, `nonmember`, `global_enum`, `show_flag_values`

---

## Data Types

*class* `enum.EnumType`

*EnumType* is the [metaclass](#) for *enum* enumerations. It is possible to subclass *EnumType* – see [Subclassing EnumType](#) for details.

*EnumType* is responsible for setting the correct `__repr__()`, `__str__()`, `__format__()`, and `__reduce__()` methods on the final *enum*, as well as creating the enum members, properly handling duplicates, providing iteration over the enum class, etc.

`_call_(cls, value, names=None, *, module=None, qualname=None, type=None, start=1, boundary=None)`

This method is called in two different ways:

- to look up an existing member:

**cls**

The enum class being called.

**value**

The value to  
lookup.

- to use the `cls` enum to create a new enum (only if the existing enum does not have any members):

**cls**

The enum  
class being  
called.

**value**

The name of  
the new  
Enum to  
create.

**names**

The names/  
values of the  
members for  
the new  
Enum.

**module**

The name of  
the module  
the new  
Enum is  
created in.

**qualname**

The actual  
location in  
the module  
where this  
Enum can be  
found.

**type**

A mix-in  
type for the  
new Enum.

**start**

The first integer value for the Enum (used by `auto`).

## boundary

How to handle out-of-range values from bit operations (`Flag` only).

### `_contains_(cls, member)`

Returns True if member belongs to the `cls`:

```
>>> some_var = Color.RED
>>> some_var in Color
True
```

### Note

In Python 3.12 it will be possible to check for member values and not just members; until then, a `TypeError` will be raised if a non-Enum-member is used in a containment check.

### `_dir_(cls)`

Returns `['__class__', '__doc__', '__members__', '__module__']` and the names of the members in `cls`:

```
>>> dir(Color)
['BLUE', 'GREEN', 'RED', '__class__', '__contai
```

### `_getattr_(cls, name)`

Returns the Enum member in *cls* matching *name*, or raises an **AttributeError**:

```
>>> Color.GREEN
<Color.GREEN: 2>
```

**`_getitem_(cls, name)`**

Returns the Enum member in *cls* matching *name*, or raises a **KeyError**:

```
>>> Color['BLUE']
<Color.BLUE: 3>
```

**`_iter_(cls)`**

Returns each member in *cls* in definition order:

```
>>> list(Color)
[<Color.RED: 1>, <Color.GREEN: 2>, <Color.BLUE: 3>]
```

**`_len_(cls)`**

Returns the number of member in *cls*:

```
>>> len(Color)
3
```

**`_reversed_(cls)`**

Returns each member in *cls* in reverse definition order:

```
>>> list(reversed(Color))
[<Color.BLUE: 3>, <Color.GREEN: 2>, <Color.RED: 1>]
```

***class* enum.Enum**

*Enum* is the base class for all *enum* enumerations.

**name**

The name used to define the Enum member:

```
>>> Color.BLUE.name
'BLUE'
```

```
'BLUE'
```

value

The value given to the `Enum` member:

```
>>> Color.RED.value
1
```

### Note

Enum member values

Member values can be anything: `int`, `str`, etc. If the exact value is unimportant you may use `auto` instances and an appropriate value will be chosen for you. See `auto` for the details.

`_ignore_`

`_ignore_` is only used during creation and is removed from the enumeration once creation is complete.

`_ignore_` is a list of names that will not become members, and whose names will also be removed from the completed enumeration. See `TimePeriod` for an example.

`_dir_(self)`

Returns `['__class__', '__doc__', '__module__', 'name', 'value']` and any public methods defined on `self._class_`:

```
>>> from datetime import date
>>> class Weekday(Enum):
...     MONDAY = 1
...     TUESDAY = 2
...     WEDNESDAY = 3
...     THURSDAY = 4
...     FRIDAY = 5
```

```

...     SATURDAY = 6
...     SUNDAY = 7
...     @classmethod
...     def today(cls):
...         print('today is %s' % cls(date.today().weekday()))
>>> dir(Weekday.SATURDAY)
['__class__', '__doc__', '__eq__', '__hash__',

```

`_generate_next_value_(name, start, count, last_values)`

**name**

The name of the member being defined (e.g. 'RED').

**start**

The start value for the Enum; the default is 1.

**count**

The number of members currently defined, not including this one.

**last\_values**

A list of the previous values.

A *staticmethod* that is used to determine the next value returned by **auto**:

```

>>> from enum import auto
>>> class PowersOfThree(Enum):
...     @staticmethod
...     def _generate_next_value_(name, start,
...         return 3 ** (count + 1)
...     FIRST = auto()
...     SECOND = auto()
>>> PowersOfThree.SECOND.value

```

`_init_subclass_(cls, **kws)`

A *classmethod* that is used to further configure subsequent subclasses. By default, does nothing.

`_missing_(cls, value)`

A *classmethod* for looking up values not found in *cls*. By default it does nothing, but can be overridden to implement custom search behavior:

```
>>> from enum import StrEnum
>>> class Build(StrEnum):
...     DEBUG = auto()
...     OPTIMIZED = auto()
...     @classmethod
...     def _missing_(cls, value):
...         value = value.lower()
...         for member in cls:
...             if member.value == value:
...                 return member
...         return None
>>> Build.DEBUG.value
'debug'
>>> Build('deBUG')
<Build.DEBUG: 'debug'>
```

`_repr_(self)`

Returns the string used for *repr()* calls. By default, returns the *Enum* name, member name, and value, but can be overridden:

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __repr__(self):
...         cls_name = self.__class__.__name__
```

```
...         return f'{cls_name}.{self.name}'
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE)
(OtherStyle.ALTERNATE, 'OtherStyle.ALTERNATE',
```

### `__str__(self)`

Returns the string used for *str()* calls. By default, returns the *Enum* name and member name, but can be overridden:

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __str__(self):
...         return f'{self.name}'
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE)
(<OtherStyle.ALTERNATE: 1>, 'ALTERNATE', 'ALTERNATE')
```

### `__format__(self)`

Returns the string used for *format()* and *f-string* calls. By default, returns `__str__()` return value, but can be overridden:

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __format__(self, spec):
...         return f'{self.name}'
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE)
(<OtherStyle.ALTERNATE: 1>, 'OtherStyle.ALTERNATE')
```

## Note

Using `auto` with `Enum` results in integers of increasing value, starting with 1.

*class* enum.IntEnum

*IntEnum* is the same as *Enum*, but its members are also integers and can be used anywhere that an integer can be used. If any integer operation is performed with an *IntEnum* member, the resulting value loses its enumeration status.

```
>>> from enum import IntEnum
>>> class Number(IntEnum):
...     ONE = 1
...     TWO = 2
...     THREE = 3
...
>>> Number.THREE
<Number.THREE: 3>
>>> Number.ONE + Number.TWO
3
>>> Number.THREE + 5
8
>>> Number.THREE == 3
True
```

### Note

Using `auto` with `IntEnum` results in integers of increasing value, starting with 1.

*Changed in version 3.11:* `__str__()` is now `int.__str__()` to better support the *replacement of existing constants* use-case. `__format__()` was already `int.__format__()` for that same reason.

*class* enum.StrEnum

*StrEnum* is the same as *Enum*, but its members are also strings and can be used in most of the same places that a string can be used. The result of any string operation performed on or with a *StrEnum* member is not part of the enumeration.

### Note

There are places in the `stdlib` that check for an exact `str` instead of a `str` subclass (i.e. `type(unknown) == str` instead of `isinstance(unknown, str)`), and in those locations you will need to use `str(StrEnum.member)`.

## Note

Using `auto` with `StrEnum` results in the lower-cased member name as the value.

## Note

`__str__()` is `str.__str__()` to better support the *replacement of existing constants* use-case. `__format__()` is likewise `str.__format__()` for that same reason.

*New in version 3.11.*

*class* `enum.Flag`

*Flag* members support the bitwise operators `&` (*AND*), `|` (*OR*), `^` (*XOR*), and `~` (*INVERT*); the results of those operators are members of the enumeration.

`__contains__(self, value)`

Returns *True* if value is in self:

```
>>> from enum import Flag, auto
>>> class Color(Flag):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
>>> purple = Color.RED | Color.BLUE
>>> white = Color.RED | Color.GREEN | Color.BLUE
>>> Color.GREEN in purple
False
>>> Color.GREEN in white
True
>>> purple in white
```

```
True
>>> white in purple
False
```

**`__iter__(self):`**

Returns all contained non-alias members:

```
>>> list(Color.RED)
[<Color.RED: 1>]
>>> list(purple)
[<Color.RED: 1>, <Color.BLUE: 4>]
```

*Changed in version 3.11:* Aliases are no longer returned during iteration.

**`__len__(self):`**

Returns number of members in flag:

```
>>> len(Color.GREEN)
1
>>> len(white)
3
```

**`__bool__(self):`**

Returns *True* if any members in flag, *False* otherwise:

```
>>> bool(Color.GREEN)
True
>>> bool(white)
True
>>> black = Color(0)
>>> bool(black)
False
```

**`__or__(self, other)`**

Returns current flag binary or'ed with other:

```
>>> Color.RED | Color.GREEN
```

```
<Color.RED|GREEN: 3>
```

### `_and_(self, other)`

Returns current flag binary and'ed with other:

```
>>> purple & white
<Color.RED|BLUE: 5>
>>> purple & Color.GREEN
<Color: 0>
```

### `_xor_(self, other)`

Returns current flag binary xor'ed with other:

```
>>> purple ^ white
<Color.GREEN: 2>
>>> purple ^ Color.GREEN
<Color.RED|GREEN|BLUE: 7>
```

### `_invert_(self):`

Returns all the flags in *type(self)* that are not in self:

```
>>> ~white
<Color: 0>
>>> ~purple
<Color.GREEN: 2>
>>> ~Color.RED
<Color.GREEN|BLUE: 6>
```

### `_numeric_repr_()`

Function used to format any remaining unnamed numeric values. Default is the value's repr; common choices are `hex()` and `oct()`.

## Note

Using `auto` with `Flag` results in integers that are powers of two, starting with 1.

*Changed in version 3.11:* The *repr()* of zero-valued flags has changed. It is now::

```
>>> Color(0)
<Color: 0>
```

*class* enum.IntFlag

*IntFlag* is the same as *Flag*, but its members are also integers and can be used anywhere that an integer can be used.

```
>>> from enum import IntFlag, auto
>>> class Color(IntFlag):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
>>> Color.RED & 2
<Color: 0>
>>> Color.RED | 2
<Color.RED|GREEN: 3>
```

If any integer operation is performed with an *IntFlag* member, the result is not an *IntFlag*:

```
>>> Color.RED + 2
3
```

If a *Flag* operation is performed with an *IntFlag* member and:

- the result is a valid *IntFlag*: an *IntFlag* is returned
- the result is not a valid *IntFlag*: the result depends on the *FlagBoundary* setting

The *repr()* of unnamed zero-valued flags has changed. It is now:

```
>>> Color(0)
<Color: 0>
```

## Note

Using `auto` with `IntFlag` results in integers that are powers of two, starting with 1.

*Changed in version 3.11:* `__str__()` is now `int.__str__()` to better support the *replacement of existing constants* use-case. `__format__()` was already `int.__format__()` for that same reason.

Inversion of an `IntFlag` now returns a positive value that is the union of all flags not in the given flag, rather than a negative value. This matches the existing `Flag` behavior.

*class* `enum.ReprEnum`

`ReprEnum` uses the `repr()` of `Enum`, but the `str()` of the mixed-in data type:

- `int.__str__()` for `IntEnum` and `IntFlag`
- `str.__str__()` for `StrEnum`

Inherit from `ReprEnum` to keep the `str()` / `format()` of the mixed-in data type instead of using the `Enum`-default `str()`.

*New in version 3.11.*

*class* `enum.EnumCheck`

`EnumCheck` contains the options used by the `verify()` decorator to ensure various constraints; failed constraints result in a `ValueError`.

UNIQUE

Ensure that each value has only one name:

```
>>> from enum import Enum, verify, UNIQUE
>>> @verify(UNIQUE)
... class Color(Enum):
...     RED = 1
```

```

...     GREEN = 2
...     BLUE = 3
...     CRIMSON = 1
Traceback (most recent call last):
...
ValueError: aliases found in <enum 'Color': CR

```

## CONTINUOUS

Ensure that there are no missing values between the lowest-valued member and the highest-valued member:

```

>>> from enum import Enum, verify, CONTINUOUS
>>> @verify(CONTINUOUS)
... class Color(Enum):
...     RED = 1
...     GREEN = 2
...     BLUE = 5
Traceback (most recent call last):
...
ValueError: invalid enum 'Color': missing value

```

## NAMED\_FLAGS

Ensure that any flag groups/masks contain only named flags – useful when values are specified instead of being generated by `auto()`:

```

>>> from enum import Flag, verify, NAMED_FLAGS
>>> @verify(NAMED_FLAGS)
... class Color(Flag):
...     RED = 1
...     GREEN = 2
...     BLUE = 4
...     WHITE = 15
...     NEON = 31
Traceback (most recent call last):
...
ValueError: invalid Flag 'Color': aliases WHITE

```

## Note

CONTINUOUS and NAMED\_FLAGS are designed to work with integer-valued members.

*New in version 3.11.*

*class* enum.FlagBoundary

*FlagBoundary* controls how out-of-range values are handled in *Flag* and its subclasses.

## STRICT

Out-of-range values cause a **ValueError** to be raised. This is the default for **Flag**:

```
>>> from enum import Flag, STRICT, auto
>>> class StrictFlag(Flag, boundary=STRICT):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
>>> StrictFlag(2**2 + 2**4)
Traceback (most recent call last):
...
ValueError: <flag 'StrictFlag'> invalid value 20
        given 0b0 10100
        allowed 0b0 00111
```

## CONFORM

Out-of-range values have invalid values removed, leaving a valid *Flag* value:

```
>>> from enum import Flag, CONFORM, auto
>>> class ConformFlag(Flag, boundary=CONFORM):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
>>> ConformFlag(2**2 + 2**4)
<ConformFlag.BLUE: 4>
```

## EJECT

Out-of-range values lose their *Flag* membership and revert to `int`.

```
>>> from enum import Flag, EJECT, auto
>>> class EjectFlag(Flag, boundary=EJECT):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
>>> EjectFlag(2**2 + 2**4)
20
```

## KEEP

Out-of-range values are kept, and the *Flag* membership is kept. This is the default for `IntFlag`:

```
>>> from enum import Flag, KEEP, auto
>>> class KeepFlag(Flag, boundary=KEEP):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
>>> KeepFlag(2**2 + 2**4)
<KeepFlag.BLUE|16: 20>
```

*New in version 3.11.*

---

## Supported `__dunder__` names

`__members__` is a read-only ordered mapping of `member_name:member` items. It is only available on the class.

`__new__()`, if specified, must create and return the enum members; it is also a very good idea to set the member's `__value__` appropriately. Once all the members are created it is no longer used.

## Supported `__sunder__` names

- `_name_` – name of the member
- `_value_` – value of the member; can be set / modified in `__new__`
- `_missing_` – a lookup function used when a value is not found; may be overridden
- `_ignore_` – a list of names, either as a `list` or a `str`, that will not be transformed into members, and will be removed from the final class
- `_order_` – used in Python 2/3 code to ensure member order is consistent (class attribute, removed during class creation)
- `_generate_next_value_` – used to get an appropriate value for an enum member; may be overridden

### Note

For standard `Enum` classes the next value chosen is the last value seen incremented by one.

For `Flag` classes the next value chosen will be the next highest power-of-two, regardless of the last value seen.

*New in version 3.6:* `_missing_`, `_order_`, `_generate_next_value_`

*New in version 3.7:* `_ignore_`

## Utilities and Decorators

`class enum.auto`

`auto` can be used in place of a value. If used, the *Enum*

machinery will call an *Enum*'s `_generate_next_value_()` to get an appropriate value. For *Enum* and *IntEnum* that appropriate value will be the last value plus one; for *Flag* and *IntFlag* it will be the first power-of-two greater than the highest value; for *StrEnum* it will be the lower-cased version of the member's name. Care must be taken if mixing *auto()* with manually specified values.

*auto* instances are only resolved when at the top level of an assignment:

- `FIRST = auto()` will work (`auto()` is replaced with `1`);
- `SECOND = auto(), -2` will work (`auto` is replaced with `2`, so `2, -2` is used to create the `SECOND` enum member);
- `THREE = [auto(), -3]` will *not* work (`<auto instance>`, `-3` is used to create the `THREE` enum member)

*Changed in version 3.11.1:* In prior versions, `auto()` had to be the only thing on the assignment line to work properly.

`_generate_next_value_` can be overridden to customize the values used by *auto*.

### Note

in 3.13 the default `_generate_next_value_` will always return the highest member value incremented by 1, and will fail if any member is an incompatible type.

### @enum.property

A decorator similar to the built-in *property*, but specifically for enumerations. It allows member attributes to have the same names as members themselves.

## Note

the *property* and the member must be defined in separate classes; for example, the *value* and *name* attributes are defined in the *Enum* class, and *Enum* subclasses can define members with the names `value` and `name`.

*New in version 3.11.*

### @enum.unique

A **class** decorator specifically for enumerations. It searches an enumeration's `__members__`, gathering any aliases it finds; if any are found **ValueError** is raised with the details:

```
>>> from enum import Enum, unique
>>> @unique
... class Mistake(Enum):
...     ONE = 1
...     TWO = 2
...     THREE = 3
...     FOUR = 3
...
Traceback (most recent call last):
...
ValueError: duplicate values found in <enum 'Mistake'>
```

### @enum.verify

A **class** decorator specifically for enumerations. Members from **EnumCheck** are used to specify which constraints should be checked on the decorated enumeration.

*New in version 3.11.*

### @enum.member

A decorator for use in enums: its target will become a member.

*New in version 3.11.*

## @enum.nonmember

A decorator for use in enums: its target will not become a member.

*New in version 3.11.*

## @enum.global\_enum

A decorator to change the `str()` and `repr()` of an enum to show its members as belonging to the module instead of its class. Should only be used when the enum members are exported to the module global namespace (see `re.RegexFlag` for an example).

*New in version 3.11.*

## enum.show\_flag\_values(value)

Return a list of all power-of-two integers contained in a flag *value*.

*New in version 3.11.*

---

# Notes

## IntEnum, StrEnum, and IntFlag

These three enum types are designed to be drop-in replacements for existing integer- and string-based values; as such, they have extra limitations:

- `__str__` uses the value and not the name of the enum member
- `__format__`, because it uses `__str__`, will also use the value of the enum member instead of its name

If you do not need/want those limitations, you can either create your own base class by mixing in the `int` or `str` type yourself:

```
>>> from enum import Enum
>>> class MyIntEnum(int, Enum):
...     pass
```

or you can reassign the appropriate `str()`, etc., in your enum:

```
>>> from enum import Enum, IntEnum
>>> class MyIntEnum(IntEnum):
...     __str__ = Enum.__str__
```

# graphlib — Functionality to operate with graph-like structures

**Source code:** [Lib/graphlib.py](#) [<https://github.com/python/cpython/tree/3.11/Lib/graphlib.py>]

---

`class graphlib.TopologicalSorter(graph = None)`

Provides functionality to topologically sort a graph of [hashable](#) nodes.

A topological order is a linear ordering of the vertices in a graph such that for every directed edge  $u \rightarrow v$  from vertex  $u$  to vertex  $v$ , vertex  $u$  comes before vertex  $v$  in the ordering. For instance, the vertices of the graph may represent tasks to be performed, and the edges may represent constraints that one task must be performed before another; in this example, a topological ordering is just a valid sequence for the tasks. A complete topological ordering is possible if and only if the graph has no directed cycles, that is, if it is a directed acyclic graph.

If the optional *graph* argument is provided it must be a dictionary representing a directed acyclic graph where the keys are nodes and the values are iterables of all predecessors of that node in the graph (the nodes that have edges that point to the value in the key). Additional nodes can be added to the graph using the [add\(\)](#) method.

In the general case, the steps required to perform the sorting of a given graph are as follows:

- Create an instance of the [TopologicalSorter](#) with an

- optional initial graph.
- Add additional nodes to the graph.
- Call `prepare()` on the graph.
- While `is_active()` is `True`, iterate over the nodes returned by `get_ready()` and process them. Call `done()` on each node as it finishes processing.

In case just an immediate sorting of the nodes in the graph is required and no parallelism is involved, the convenience method `TopologicalSorter.static_order()` can be used directly:

```
>>> graph = {"D": {"B", "C"}, "C": {"A"}, "B": {"A"}}
>>> ts = TopologicalSorter(graph)
>>> tuple(ts.static_order())
('A', 'C', 'B', 'D')
```

The class is designed to easily support parallel processing of the nodes as they become ready. For instance:

```
topological_sorter = TopologicalSorter()

# Add nodes to 'topological_sorter'...

topological_sorter.prepare()
while topological_sorter.is_active():
    for node in topological_sorter.get_ready():
        # Worker threads or processes take nodes to
        # 'task_queue' queue.
        task_queue.put(node)

    # When the work for a node is done, workers put
    # 'finalized_tasks_queue' so we can get more nodes
    # The definition of 'is_active()' guarantees that
    # least one node has been placed on 'task_queue'
    # been passed to 'done()', so this blocking 'get'
    # succeed. After calling 'done()', we loop back
    # again, so put newly freed nodes on 'task_queue'
```

```
# logically possible.  
node = finalized_tasks_queue.get()  
topological_sorter.done(node)
```

### `add(node, *predecessors)`

Add a new node and its predecessors to the graph. Both the *node* and all elements in *predecessors* must be [hashable](#).

If called multiple times with the same node argument, the set of dependencies will be the union of all dependencies passed in.

It is possible to add a node with no dependencies (*predecessors* is not provided) or to provide a dependency twice. If a node that has not been provided before is included among *predecessors* it will be automatically added to the graph with no predecessors of its own.

Raises [ValueError](#) if called after [prepare\(\)](#).

### `prepare()`

Mark the graph as finished and check for cycles in the graph. If any cycle is detected, [CycleError](#) will be raised, but [get\\_ready\(\)](#) can still be used to obtain as many nodes as possible until cycles block more progress. After a call to this function, the graph cannot be modified, and therefore no more nodes can be added using [add\(\)](#).

### `is_active()`

Returns `True` if more progress can be made and `False` otherwise. Progress can be made if cycles do not block the resolution and either there are still nodes ready that haven't yet been returned by [TopologicalSorter.get\\_ready\(\)](#) or the number of nodes marked [TopologicalSorter.done\(\)](#) is less than the number that have been returned by

`TopologicalSorter.get_ready()`.

The `__bool__()` method of this class defers to this function, so instead of:

```
if ts.is_active():  
    ...
```

it is possible to simply do:

```
if ts:  
    ...
```

Raises **ValueError** if called without calling `prepare()` previously.

`done(*nodes)`

Marks a set of nodes returned by `TopologicalSorter.get_ready()` as processed, unblocking any successor of each node in *nodes* for being returned in the future by a call to `TopologicalSorter.get_ready()`.

Raises **ValueError** if any node in *nodes* has already been marked as processed by a previous call to this method or if a node was not added to the graph by using `TopologicalSorter.add()`, if called without calling `prepare()` or if node has not yet been returned by `get_ready()`.

`get_ready()`

Returns a `tuple` with all the nodes that are ready. Initially it returns all nodes with no predecessors, and once those are marked as processed by calling `TopologicalSorter.done()`, further calls will return all new nodes that have all their predecessors already processed. Once no more progress can be made, empty tuples are returned.

Raises **ValueError** if called without calling

`prepare()` previously.

### `static_order()`

Returns an iterator object which will iterate over nodes in a topological order. When using this method, `prepare()` and `done()` should not be called. This method is equivalent to:

```
def static_order(self):
    self.prepare()
    while self.is_active():
        node_group = self.get_ready()
        yield from node_group
        self.done(*node_group)
```

The particular order that is returned may depend on the specific order in which the items were inserted in the graph. For example:

```
>>> ts = TopologicalSorter()
>>> ts.add(3, 2, 1)
>>> ts.add(1, 0)
>>> print([*ts.static_order()])
[2, 0, 1, 3]

>>> ts2 = TopologicalSorter()
>>> ts2.add(1, 0)
>>> ts2.add(3, 2, 1)
>>> print([*ts2.static_order()])
[0, 2, 1, 3]
```

This is due to the fact that “0” and “2” are in the same level in the graph (they would have been returned in the same call to `get_ready()`) and the order between them is determined by the order of insertion.

If any cycle is detected, `CycleError` will be raised.

*New in version 3.9.*

# Exceptions

The `graphlib` module defines the following exception classes:

*exception* `graphlib.CycleError`

Subclass of `ValueError` raised by `TopologicalSorter.prepare()` if cycles exist in the working graph. If multiple cycles exist, only one undefined choice among them will be reported and included in the exception.

The detected cycle can be accessed via the second element in the `args` attribute of the exception instance and consists in a list of nodes, such that each node is, in the graph, an immediate predecessor of the next node in the list. In the reported list, the first and the last node will be the same, to make it clear that it is cyclic.

# Numeric and Mathematical Modules

The modules described in this chapter provide numeric and math-related functions and data types. The `numbers` module defines an abstract hierarchy of numeric types. The `math` and `cmath` modules contain various mathematical functions for floating-point and complex numbers. The `decimal` module supports exact representations of decimal numbers, using arbitrary precision arithmetic.

The following modules are documented in this chapter:

- `numbers` — Numeric abstract base classes
  - The numeric tower
  - Notes for type implementors
    - Adding More Numeric ABCs
    - Implementing the arithmetic operations
- `math` — Mathematical functions
  - Number-theoretic and representation functions
  - Power and logarithmic functions
  - Trigonometric functions
  - Angular conversion
  - Hyperbolic functions
  - Special functions
  - Constants
- `cmath` — Mathematical functions for complex numbers
  - Conversions to and from polar coordinates
  - Power and logarithmic functions
  - Trigonometric functions

- Hyperbolic functions
  - Classification functions
  - Constants
- **decimal** — Decimal fixed point and floating point arithmetic
  - Quick-start Tutorial
  - Decimal objects
    - Logical operands
      - Context objects
      - Constants
      - Rounding modes
      - Signals
      - Floating Point Notes
    - Mitigating round-off error with increased precision
    - Special values
  - Working with threads
  - Recipes
  - Decimal FAQ
- **fractions** — Rational numbers
- **random** — Generate pseudo-random numbers
  - Bookkeeping functions
  - Functions for bytes
  - Functions for integers
  - Functions for sequences
  - Real-valued distributions
  - Alternative Generator
  - Notes on Reproducibility
  - Examples
  - Recipes
- **statistics** — Mathematical statistics functions
  - Averages and measures of central location
  - Measures of spread

- Statistics for relations between two inputs
- Function details
- Exceptions
- **NormalDist** objects

■ **NormalDist** Examples and Recipes

# numbers — Numeric abstract base classes

Source code: [Lib/numbers.py](https://github.com/python/cpython/tree/3.11/Lib/numbers.py) [https://github.com/python/cpython/tree/3.11/Lib/numbers.py]

---

The **numbers** module ([PEP 3141](https://peps.python.org/pep-3141/) [https://peps.python.org/pep-3141/]) defines a hierarchy of numeric **abstract base classes** which progressively define more operations. None of the types defined in this module are intended to be instantiated.

*class* numbers.Number

The root of the numeric hierarchy. If you just want to check if an argument *x* is a number, without caring what kind, use `isinstance(x, Number)`.

## The numeric tower

*class* numbers.Complex

Subclasses of this type describe complex numbers and include the operations that work on the built-in **complex** type.

These are: conversions to **complex** and **bool**, **real**, **imag**, **+**, **-**, **\***, **/**, **\*\***, **abs()**, **conjugate()**, **==**, and **!=**. All except **-** and **!=** are abstract.

*real*

Abstract. Retrieves the real component of this number.

*imag*

Abstract. Retrieves the imaginary component of this number.

*abstractmethod* conjugate()

Abstract. Returns the complex conjugate. For example,  
`(1+3j).conjugate() == (1-3j)`.

*class* numbers.Real

To **Complex**, **Real** adds the operations that work on real numbers.

In short, those are: a conversion to **float**, **math.trunc()**, **round()**, **math.floor()**, **math.ceil()**, **divmod()**, **//**, **%**, **<**, **<=**, **>**, and **>=**.

Real also provides defaults for **complex()**, **real**, **imag**, and **conjugate()**.

*class* numbers.Rational

Subtypes **Real** and adds **numerator** and **denominator** properties. It also provides a default for **float()**.

The **numerator** and **denominator** values should be instances of **Integral** and should be in lowest terms with **denominator** positive.

**numerator**

Abstract.

**denominator**

Abstract.

*class* numbers.Integral

Subtypes **Rational** and adds a conversion to **int**. Provides defaults for **float()**, **numerator**, and **denominator**.

Adds abstract methods for **pow()** with modulus and bit-string operations: **<<**, **>>**, **&**, **^**, **|**, **~**.

## Notes for type implementors

Implementors should be careful to make equal numbers equal and hash them to the same values. This may be subtle if there are two

different extensions of the real numbers. For example, `fractions.Fraction` implements `hash()` as follows:

```
def __hash__(self):
    if self.denominator == 1:
        # Get integers right.
        return hash(self.numerator)
    # Expensive check, but definitely correct.
    if self == float(self):
        return hash(float(self))
    else:
        # Use tuple's hash to avoid a high collision rate
        # for simple fractions.
        return hash((self.numerator, self.denominator))
```

## Adding More Numeric ABCs

There are, of course, more possible ABCs for numbers, and this would be a poor hierarchy if it precluded the possibility of adding those. You can add `MyFoo` between `Complex` and `Real` with:

```
class MyFoo(Complex): ...
MyFoo.register(Real)
```

## Implementing the arithmetic operations

We want to implement the arithmetic operations so that mixed-mode operations either call an implementation whose author knew about the types of both arguments, or convert both to the nearest built-in type and do the operation there. For subtypes of `Integral`, this means that `__add__()` and `__radd__()` should be defined as:

```
class MyIntegral(Integral):

    def __add__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(self, other)
        elif isinstance(other, OtherTypeIKnowAbout):
```

```

        return do_my_other_adding_stuff(self, other)
    else:
        return NotImplemented

def __radd__(self, other):
    if isinstance(other, MyIntegral):
        return do_my_adding_stuff(other, self)
    elif isinstance(other, OtherTypeIKnowAbout):
        return do_my_other_adding_stuff(other, self)
    elif isinstance(other, Integral):
        return int(other) + int(self)
    elif isinstance(other, Real):
        return float(other) + float(self)
    elif isinstance(other, Complex):
        return complex(other) + complex(self)
    else:
        return NotImplemented

```

There are 5 different cases for a mixed-type operation on subclasses of **Complex**. I'll refer to all of the above code that doesn't refer to `MyIntegral` and `OtherTypeIKnowAbout` as "boilerplate". `a` will be an instance of `A`, which is a subtype of **Complex** (`a : A <: Complex`), and `b : B <: Complex`. I'll consider `a + b`:

1. If `A` defines an `__add__()` which accepts `b`, all is well.
2. If `A` falls back to the boilerplate code, and it were to return a value from `__add__()`, we'd miss the possibility that `B` defines a more intelligent `__radd__()`, so the boilerplate should return **NotImplemented** from `__add__()`. (Or `A` may not implement `__add__()` at all.)
3. Then `B`'s `__radd__()` gets a chance. If it accepts `a`, all is well.
4. If it falls back to the boilerplate, there are no more possible methods to try, so this is where the default implementation should live.
5. If `B <: A`, Python tries `B.__radd__` before `A.__add__`. This is ok, because it

was implemented with knowledge of `A`, so it can handle those instances before delegating to `Complex`.

If `A <: Complex` and `B <: Real` without sharing any other knowledge, then the appropriate shared operation is the one involving the built in `complex`, and both `__radd__()` s land there, so `a+b == b+a`.

Because most of the operations on any given type will be very similar, it can be useful to define a helper function which generates the forward and reverse instances of any given operator. For example, `fractions.Fraction` uses:

```
def _operator_fallbacks(monomorphic_operator, fallback_operator):
    def forward(a, b):
        if isinstance(b, (int, Fraction)):
            return monomorphic_operator(a, b)
        elif isinstance(b, float):
            return fallback_operator(float(a), b)
        elif isinstance(b, complex):
            return fallback_operator(complex(a), b)
        else:
            return NotImplemented
    forward.__name__ = '__' + fallback_operator.__name__
    forward.__doc__ = monomorphic_operator.__doc__

    def reverse(b, a):
        if isinstance(a, Rational):
            # Includes ints.
            return monomorphic_operator(a, b)
        elif isinstance(a, Real):
            return fallback_operator(float(a), float(b))
        elif isinstance(a, Complex):
            return fallback_operator(complex(a), complex(b))
        else:
            return NotImplemented
    reverse.__name__ = '__r' + fallback_operator.__name__
    reverse.__doc__ = monomorphic_operator.__doc__
```

```
return forward, reverse
```

```
def _add(a, b):
```

```
    """a + b"""
```

```
    return Fraction(a.numerator * b.denominator +  
                    b.numerator * a.denominator,  
                    a.denominator * b.denominator)
```

```
__add__, __radd__ = _operator_fallbacks(_add, operator.a
```

```
# ...
```

# math — Mathematical functions

---

This module provides access to the mathematical functions defined by the C standard.

These functions cannot be used with complex numbers; use the functions of the same name from the `cmath` module if you require support for complex numbers. The distinction between functions which support complex numbers and those which don't is made since most users do not want to learn quite as much mathematics as required to understand complex numbers. Receiving an exception instead of a complex result allows earlier detection of the unexpected complex number used as a parameter, so that the programmer can determine how and why it was generated in the first place.

The following functions are provided by this module. Except when explicitly noted otherwise, all return values are floats.

## Number-theoretic and representation functions

`math.ceil(x)`

Return the ceiling of  $x$ , the smallest integer greater than or equal to  $x$ . If  $x$  is not a float, delegates to `x.__ceil__`, which should return an `Integral` value.

`math.comb(n, k)`

Return the number of ways to choose  $k$  items from  $n$  items without repetition and without order.

Evaluates to  $n! / (k! * (n - k)!)$  when  $k \leq n$  and evaluates to zero when  $k > n$ .

Also called the binomial coefficient because it is equivalent to the coefficient of  $k$ -th term in polynomial expansion of  $(1 + x)^n$ .

Raises **TypeError** if either of the arguments are not integers. Raises **ValueError** if either of the arguments are negative.

*New in version 3.8.*

`math.copysign(x, y)`

Return a float with the magnitude (absolute value) of  $x$  but the sign of  $y$ . On platforms that support signed zeros, `copysign(1.0, -0.0)` returns `-1.0`.

`math.fabs(x)`

Return the absolute value of  $x$ .

`math.factorial(n)`

Return  $n$  factorial as an integer. Raises **ValueError** if  $n$  is not integral or is negative.

*Deprecated since version 3.9:* Accepting floats with integral values (like `5.0`) is deprecated.

`math.floor(x)`

Return the floor of  $x$ , the largest integer less than or equal to  $x$ . If  $x$  is not a float, delegates to `x.__floor__`, which should return an **Integral** value.

`math.fmod(x, y)`

Return `fmod(x, y)`, as defined by the platform C library. Note that the Python expression `x % y` may not return the same result. The intent of the C standard is that `fmod(x, y)` be exactly (mathematically; to infinite precision) equal to

$x - n \cdot y$  for some integer  $n$  such that the result has the same sign as  $x$  and magnitude less than  $\text{abs}(y)$ . Python's  $x \% y$  returns a result with the sign of  $y$  instead, and may not be exactly computable for float arguments. For example, `fmod(-1e-100, 1e100)` is `-1e-100`, but the result of Python's `-1e-100 \% 1e100` is `1e100-1e-100`, which cannot be represented exactly as a float, and rounds to the surprising `1e100`. For this reason, function `fmod()` is generally preferred when working with floats, while Python's  $x \% y$  is preferred when working with integers.

### `math.frexp(x)`

Return the mantissa and exponent of  $x$  as the pair  $(m, e)$ .  $m$  is a float and  $e$  is an integer such that  $x == m * 2^{**}e$  exactly. If  $x$  is zero, returns  $(0.0, 0)$ , otherwise  $0.5 \leq \text{abs}(m) < 1$ . This is used to “pick apart” the internal representation of a float in a portable way.

### `math.fsum(iterable)`

Return an accurate floating point sum of values in the iterable. Avoids loss of precision by tracking multiple intermediate partial sums:

```
>>> sum([.1, .1, .1, .1, .1, .1, .1, .1, .1, .1])
0.9999999999999999
>>> fsum([.1, .1, .1, .1, .1, .1, .1, .1, .1, .1])
1.0
```

The algorithm's accuracy depends on IEEE-754 arithmetic guarantees and the typical case where the rounding mode is half-even. On some non-Windows builds, the underlying C library uses extended precision addition and may occasionally double-round an intermediate sum causing it to be off in its least significant bit.

For further discussion and two alternative approaches, see the [ASPN cookbook recipes for accurate floating point summation](https://code.activestate.com/recipes/393090/) [<https://code.activestate.com/recipes/393090/>].

`math.gcd(*integers)`

Return the greatest common divisor of the specified integer arguments. If any of the arguments is nonzero, then the returned value is the largest positive integer that is a divisor of all arguments. If all arguments are zero, then the returned value is 0. `gcd()` without arguments returns 0.

*New in version 3.5.*

*Changed in version 3.9:* Added support for an arbitrary number of arguments. Formerly, only two arguments were supported.

`math.isclose(a, b, *, rel_tol=1e-09, abs_tol=0.0)`

Return `True` if the values *a* and *b* are close to each other and `False` otherwise.

Whether or not two values are considered close is determined according to given absolute and relative tolerances.

*rel\_tol* is the relative tolerance – it is the maximum allowed difference between *a* and *b*, relative to the larger absolute value of *a* or *b*. For example, to set a tolerance of 5%, pass `rel_tol=0.05`. The default tolerance is `1e-09`, which assures that the two values are the same within about 9 decimal digits. *rel\_tol* must be greater than zero.

*abs\_tol* is the minimum absolute tolerance – useful for comparisons near zero. *abs\_tol* must be at least zero.

If no errors occur, the result will be: `abs(a-b) <= max(rel_tol * max(abs(a), abs(b)), abs_tol)`.

The IEEE 754 special values of `NaN`, `inf`, and `-inf` will be handled according to IEEE rules. Specifically, `NaN` is not considered close to any other value, including `NaN`. `inf` and `-inf` are only considered close to themselves.

*New in version 3.5.*

**See also**

**PEP 485** [<https://peps.python.org/pep-0485/>] – A function for testing approximate equality

`math.isfinite(x)`

Return `True` if *x* is neither an infinity nor a NaN, and `False` otherwise. (Note that `0.0` is considered finite.)

*New in version 3.2.*

`math.isinf(x)`

Return `True` if *x* is a positive or negative infinity, and `False` otherwise.

`math.isnan(x)`

Return `True` if *x* is a NaN (not a number), and `False` otherwise.

`math.isqrt(n)`

Return the integer square root of the nonnegative integer *n*. This is the floor of the exact square root of *n*, or equivalently the greatest integer *a* such that  $a^2 \leq n$ .

For some applications, it may be more convenient to have the least integer *a* such that  $n \leq a^2$ , or in other words the ceiling of the exact square root of *n*. For positive *n*, this can be computed using `a = 1 + isqrt(n - 1)`.

*New in version 3.8.*

`math.lcm(*integers)`

Return the least common multiple of the specified integer arguments. If all arguments are nonzero, then the returned value is the smallest positive integer that is a multiple of all arguments. If any of the arguments is zero, then the returned value is `0`. `lcm()` without arguments returns `1`.

*New in version 3.9.*

`math.ldexp(x, i)`

Return  $x * (2^{**i})$ . This is essentially the inverse of function `frexp()`.

`math.modf(x)`

Return the fractional and integer parts of  $x$ . Both results carry the sign of  $x$  and are floats.

`math.nextafter(x, y)`

Return the next floating-point value after  $x$  towards  $y$ .

If  $x$  is equal to  $y$ , return  $y$ .

Examples:

- `math.nextafter(x, math.inf)` goes up: towards positive infinity.
- `math.nextafter(x, -math.inf)` goes down: towards minus infinity.
- `math.nextafter(x, 0.0)` goes towards zero.
- `math.nextafter(x, math.copysign(math.inf, x))` goes away from zero.

See also `math.ulp()`.

*New in version 3.9.*

`math.perm(n, k=None)`

Return the number of ways to choose  $k$  items from  $n$  items without repetition and with order.

Evaluates to  $n! / (n - k)!$  when  $k \leq n$  and evaluates to zero when  $k > n$ .

If  $k$  is not specified or is `None`, then  $k$  defaults to  $n$  and the function returns  $n!$ .

Raises **TypeError** if either of the arguments are not integers. Raises **ValueError** if either of the arguments are negative.

*New in version 3.8.*

`math.prod(iterable, *, start=1)`

Calculate the product of all the elements in the input *iterable*. The default *start* value for the product is 1.

When the iterable is empty, return the start value. This function is intended specifically for use with numeric values and may reject non-numeric types.

*New in version 3.8.*

`math.remainder(x, y)`

Return the IEEE 754-style remainder of *x* with respect to *y*. For finite *x* and finite nonzero *y*, this is the difference  $x - n*y$ , where *n* is the closest integer to the exact value of the quotient  $x / y$ . If  $x / y$  is exactly halfway between two consecutive integers, the nearest *even* integer is used for *n*. The remainder  $r = \text{remainder}(x, y)$  thus always satisfies  $\text{abs}(r) \leq 0.5 * \text{abs}(y)$ .

Special cases follow IEEE 754: in particular, `remainder(x, math.inf)` is *x* for any finite *x*, and `remainder(x, 0)` and `remainder(math.inf, x)` raise **ValueError** for any non-NaN *x*. If the result of the remainder operation is zero, that zero will have the same sign as *x*.

On platforms using IEEE 754 binary floating-point, the result of this operation is always exactly representable: no rounding error is introduced.

*New in version 3.7.*

`math.trunc(x)`

Return *x* with the fractional part removed, leaving the integer

part. This rounds toward 0: `trunc()` is equivalent to `floor()` for positive  $x$ , and equivalent to `ceil()` for negative  $x$ . If  $x$  is not a float, delegates to `x.__trunc__`, which should return an `Integral` value.

## `math.ulp(x)`

Return the value of the least significant bit of the float  $x$ :

- If  $x$  is a NaN (not a number), return  $x$ .
- If  $x$  is negative, return `ulp(-x)`.
- If  $x$  is a positive infinity, return  $x$ .
- If  $x$  is equal to zero, return the smallest positive *denormalized* representable float (smaller than the minimum positive *normalized* float, `sys.float_info.min`).
- If  $x$  is equal to the largest positive representable float, return the value of the least significant bit of  $x$ , such that the first float smaller than  $x$  is  $x - \text{ulp}(x)$ .
- Otherwise ( $x$  is a positive finite number), return the value of the least significant bit of  $x$ , such that the first float bigger than  $x$  is  $x + \text{ulp}(x)$ .

ULP stands for “Unit in the Last Place”.

See also `math.nextafter()` and `sys.float_info.epsilon`.

*New in version 3.9.*

Note that `frexp()` and `modf()` have a different call/return pattern than their C equivalents: they take a single argument and return a pair of values, rather than returning their second return value through an ‘output parameter’ (there is no such thing in Python).

For the `ceil()`, `floor()`, and `modf()` functions, note that *all* floating-point numbers of sufficiently large magnitude are exact integers. Python floats typically carry no more than 53 bits of precision (the same as the platform C double type), in which case any float  $x$  with `abs(x) >= 2**52` necessarily has no fractional

bits.

## Power and logarithmic functions

`math.cbrt(x)`

Return the cube root of  $x$ .

*New in version 3.11.*

`math.exp(x)`

Return  $e$  raised to the power  $x$ , where  $e = 2.718281\dots$  is the base of natural logarithms. This is usually more accurate than `math.e ** x` or `pow(math.e, x)`.

`math.exp2(x)`

Return 2 raised to the power  $x$ .

*New in version 3.11.*

`math.expm1(x)`

Return  $e$  raised to the power  $x$ , minus 1. Here  $e$  is the base of natural logarithms. For small floats  $x$ , the subtraction in `exp(x) - 1` can result in a [significant loss of precision](https://en.wikipedia.org/wiki/Loss_of_significance) [https://en.wikipedia.org/wiki/Loss\_of\_significance]; the `expm1()` function provides a way to compute this quantity to full precision:

```
>>> from math import exp, expm1
>>> exp(1e-5) - 1 # gives result accurate to 11 pl
1.0000050000069649e-05
>>> expm1(1e-5) # result accurate to full precis
1.0000050000166668e-05
```

*New in version 3.2.*

`math.log(x[, base])`

With one argument, return the natural logarithm of  $x$  (to base

*e*).

With two arguments, return the logarithm of  $x$  to the given base, calculated as  $\log(x) / \log(\text{base})$ .

`math.log1p(x)`

Return the natural logarithm of  $1 + x$  (base  $e$ ). The result is calculated in a way which is accurate for  $x$  near zero.

`math.log2(x)`

Return the base-2 logarithm of  $x$ . This is usually more accurate than `log(x, 2)`.

*New in version 3.3.*

### See also

`int.bit_length()` returns the number of bits necessary to represent an integer in binary, excluding the sign and leading zeros.

`math.log10(x)`

Return the base-10 logarithm of  $x$ . This is usually more accurate than `log(x, 10)`.

`math.pow(x, y)`

Return  $x$  raised to the power  $y$ . Exceptional cases follow the IEEE 754 standard as far as possible. In particular, `pow(1.0, x)` and `pow(x, 0.0)` always return `1.0`, even when  $x$  is a zero or a NaN. If both  $x$  and  $y$  are finite,  $x$  is negative, and  $y$  is not an integer then `pow(x, y)` is undefined, and raises `ValueError`.

Unlike the built-in `**` operator, `math.pow()` converts both its arguments to type `float`. Use `**` or the built-in `pow()` function for computing exact integer powers.

*Changed in version 3.11:* The special cases `pow(0.0, -inf)` and `pow(-0.0, -inf)` were changed to return `inf` instead of raising `ValueError`, for consistency with IEEE 754.

`math.sqrt(x)`

Return the square root of  $x$ .

## Trigonometric functions

`math.acos(x)`

Return the arc cosine of  $x$ , in radians. The result is between `0` and `pi`.

`math.asin(x)`

Return the arc sine of  $x$ , in radians. The result is between `-pi/2` and `pi/2`.

`math.atan(x)`

Return the arc tangent of  $x$ , in radians. The result is between `-pi/2` and `pi/2`.

`math.atan2(y, x)`

Return `atan(y / x)`, in radians. The result is between `-pi` and `pi`. The vector in the plane from the origin to point `(x, y)` makes this angle with the positive X axis. The point of `atan2()` is that the signs of both inputs are known to it, so it can compute the correct quadrant for the angle. For example, `atan(1)` and `atan2(1, 1)` are both `pi/4`, but `atan2(-1, -1)` is `-3*pi/4`.

`math.cos(x)`

Return the cosine of  $x$  radians.

`math.dist(p, q)`

Return the Euclidean distance between two points  $p$  and  $q$ , each given as a sequence (or iterable) of coordinates. The two points must have the same dimension.

Roughly equivalent to:

```
sqrt(sum((px - qx) ** 2.0 for px, qx in zip(p, q)))
```

*New in version 3.8.*

`math.hypot(*coordinates)`

Return the Euclidean norm, `sqrt(sum(x**2 for x in coordinates))`. This is the length of the vector from the origin to the point given by the coordinates.

For a two dimensional point  $(x, y)$ , this is equivalent to computing the hypotenuse of a right triangle using the Pythagorean theorem, `sqrt(x*x + y*y)`.

*Changed in version 3.8:* Added support for n-dimensional points. Formerly, only the two dimensional case was supported.

*Changed in version 3.10:* Improved the algorithm's accuracy so that the maximum error is under 1 ulp (unit in the last place). More typically, the result is almost always correctly rounded to within 1/2 ulp.

`math.sin(x)`

Return the sine of  $x$  radians.

`math.tan(x)`

Return the tangent of  $x$  radians.

## Angular conversion

`math.degrees(x)`

Convert angle  $x$  from radians to degrees.

`math.radians(x)`

Convert angle  $x$  from degrees to radians.

## Hyperbolic functions

**Hyperbolic functions** [[https://en.wikipedia.org/wiki/Hyperbolic\\_function](https://en.wikipedia.org/wiki/Hyperbolic_function)] are analogs of trigonometric functions that are based on hyperbolas instead of circles.

`math.acosh(x)`

Return the inverse hyperbolic cosine of  $x$ .

`math.asinh(x)`

Return the inverse hyperbolic sine of  $x$ .

`math.atanh(x)`

Return the inverse hyperbolic tangent of  $x$ .

`math.cosh(x)`

Return the hyperbolic cosine of  $x$ .

`math.sinh(x)`

Return the hyperbolic sine of  $x$ .

`math.tanh(x)`

Return the hyperbolic tangent of  $x$ .

## Special functions

`math.erf(x)`

Return the **error function** [[https://en.wikipedia.org/wiki/Error\\_function](https://en.wikipedia.org/wiki/Error_function)] at  $x$ .

The **`erf()`** function can be used to compute traditional statistical functions such as the **cumulative standard normal**

[distribution](https://en.wikipedia.org/wiki/distribution) [https://en.wikipedia.org/wiki/Normal\_distribution#Cumulative\_distribution\_functions]:

```
def phi(x):  
    'Cumulative distribution function for the standard normal distribution'  
    return (1.0 + erf(x / sqrt(2.0))) / 2.0
```

*New in version 3.2.*

`math.erfc(x)`

Return the complementary error function at  $x$ . The [complementary error function](https://en.wikipedia.org/wiki/complementary_error_function) [https://en.wikipedia.org/wiki/Error\_function] is defined as  $1.0 - \text{erf}(x)$ . It is used for large values of  $x$  where a subtraction from one would cause a [loss of significance](https://en.wikipedia.org/wiki/Loss_of_significance) [https://en.wikipedia.org/wiki/Loss\_of\_significance].

*New in version 3.2.*

`math.gamma(x)`

Return the [Gamma function](https://en.wikipedia.org/wiki/Gamma_function) [https://en.wikipedia.org/wiki/Gamma\_function] at  $x$ .

*New in version 3.2.*

`math.lgamma(x)`

Return the natural logarithm of the absolute value of the Gamma function at  $x$ .

*New in version 3.2.*

## Constants

`math.pi`

The mathematical constant  $\pi = 3.141592\dots$ , to available precision.

`math.e`

The mathematical constant  $e = 2.718281\dots$ , to available

precision.

### `math.tau`

The mathematical constant  $\tau = 6.283185\dots$ , to available precision. Tau is a circle constant equal to  $2\pi$ , the ratio of a circle's circumference to its radius. To learn more about Tau, check out Vi Hart's video [Pi is \(still\) Wrong](https://www.youtube.com/watch?v=jG7vhMMXagQ) [https://www.youtube.com/watch?v=jG7vhMMXagQ], and start celebrating [Tau day](https://tauday.com/) [https://tauday.com/] by eating twice as much pie!

*New in version 3.6.*

### `math.inf`

A floating-point positive infinity. (For negative infinity, use `-math.inf`.) Equivalent to the output of `float('inf')`.

*New in version 3.5.*

### `math.nan`

A floating-point “not a number” (NaN) value. Equivalent to the output of `float('nan')`. Due to the requirements of the [IEEE-754 standard](https://en.wikipedia.org/wiki/IEEE_754) [https://en.wikipedia.org/wiki/IEEE\_754], `math.nan` and `float('nan')` are not considered to equal to any other numeric value, including themselves. To check whether a number is a NaN, use the `isnan()` function to test for NaNs instead of `is` or `==`. Example:

```
>>> import math
>>> math.nan == math.nan
False
>>> float('nan') == float('nan')
False
>>> math.isnan(math.nan)
True
>>> math.isnan(float('nan'))
True
```

*Changed in version 3.11:* It is now always available.

*New in version 3.5.*

**CPython implementation detail:** The `math` module consists mostly of thin wrappers around the platform C math library functions. Behavior in exceptional cases follows Annex F of the C99 standard where appropriate. The current implementation will raise `ValueError` for invalid operations like `sqrt(-1.0)` or `log(0.0)` (where C99 Annex F recommends signaling invalid operation or divide-by-zero), and `OverflowError` for results that overflow (for example, `exp(1000.0)`). A NaN will not be returned from any of the functions above unless one or more of the input arguments was a NaN; in that case, most functions will return a NaN, but (again following C99 Annex F) there are some exceptions to this rule, for example `pow(float('nan'), 0.0)` or `hypot(float('nan'), float('inf'))`.

Note that Python makes no effort to distinguish signaling NaNs from quiet NaNs, and behavior for signaling NaNs remains unspecified. Typical behavior is to treat all NaNs as though they were quiet.

**See also**

**Module** `cmath`

Complex number versions of many of these functions.

# `cmath` — Mathematical functions for complex numbers

---

This module provides access to mathematical functions for complex numbers. The functions in this module accept integers, floating-point numbers or complex numbers as arguments. They will also accept any Python object that has either a `__complex__()` or a `__float__()` method: these methods are used to convert the object to a complex or floating-point number, respectively, and the function is then applied to the result of the conversion.

## Note

For functions involving branch cuts, we have the problem of deciding how to define those functions on the cut itself. Following Kahan’s “Branch cuts for complex elementary functions” paper, as well as Annex G of C99 and later C standards, we use the sign of zero to distinguish one side of the branch cut from the other: for a branch cut along (a portion of) the real axis we look at the sign of the imaginary part, while for a branch cut along the imaginary axis we look at the sign of the real part.

For example, the `cmath.sqrt()` function has a branch cut along the negative real axis. An argument of `complex(-2.0, -0.0)` is treated as though it lies *below* the branch cut, and so gives a result on the negative imaginary axis:

```
>>> cmath.sqrt(complex(-2.0, -0.0))
-1.4142135623730951j
```

But an argument of `complex(-2.0, 0.0)` is treated as though it lies above the branch cut:

```
>>> cmath.sqrt(complex(-2.0, 0.0))
1.4142135623730951j
```

## Conversions to and from polar coordinates

A Python complex number  $z$  is stored internally using *rectangular* or *Cartesian* coordinates. It is completely determined by its *real part*  $z.\text{real}$  and its *imaginary part*  $z.\text{imag}$ . In other words:

```
z == z.real + z.imag*1j
```

*Polar coordinates* give an alternative way to represent a complex number. In polar coordinates, a complex number  $z$  is defined by the modulus  $r$  and the phase angle  $\phi$ . The modulus  $r$  is the distance from  $z$  to the origin, while the phase  $\phi$  is the counterclockwise angle, measured in radians, from the positive x-axis to the line segment that joins the origin to  $z$ .

The following functions can be used to convert from the native rectangular coordinates to polar coordinates and back.

`cmath.phase(x)`

Return the phase of  $x$  (also known as the *argument* of  $x$ ), as a float. `phase(x)` is equivalent to `math.atan2(x.imag, x.real)`. The result lies in the range  $[-\pi, \pi]$ , and the branch cut for this operation lies along the negative real axis. The sign of the result is the same as the sign of  $x.\text{imag}$ , even when  $x.\text{imag}$  is zero:

```
>>> phase(complex(-1.0, 0.0))
3.141592653589793
>>> phase(complex(-1.0, -0.0))
-3.141592653589793
```

### Note

The modulus (absolute value) of a complex number  $x$  can be

computed using the built-in `abs()` function. There is no separate `cmath` module function for this operation.

`cmath.polar(x)`

Return the representation of  $x$  in polar coordinates. Returns a pair  $(r, \text{phi})$  where  $r$  is the modulus of  $x$  and  $\text{phi}$  is the phase of  $x$ . `polar(x)` is equivalent to `(abs(x), phase(x))`.

`cmath.rect(r, phi)`

Return the complex number  $x$  with polar coordinates  $r$  and  $\text{phi}$ . Equivalent to `r * (math.cos(phi) + math.sin(phi)*1j)`.

## Power and logarithmic functions

`cmath.exp(x)`

Return  $e$  raised to the power  $x$ , where  $e$  is the base of natural logarithms.

`cmath.log(x[, base])`

Returns the logarithm of  $x$  to the given *base*. If the *base* is not specified, returns the natural logarithm of  $x$ . There is one branch cut, from 0 along the negative real axis to  $-\infty$ .

`cmath.log10(x)`

Return the base-10 logarithm of  $x$ . This has the same branch cut as `log()`.

`cmath.sqrt(x)`

Return the square root of  $x$ . This has the same branch cut as `log()`.

## Trigonometric functions

`cmath.acos( $x$ )`

Return the arc cosine of  $x$ . There are two branch cuts: One extends right from 1 along the real axis to  $\infty$ . The other extends left from -1 along the real axis to  $-\infty$ .

`cmath.asin( $x$ )`

Return the arc sine of  $x$ . This has the same branch cuts as `acos()`.

`cmath.atan( $x$ )`

Return the arc tangent of  $x$ . There are two branch cuts: One extends from  $1j$  along the imaginary axis to  $\infty j$ . The other extends from  $-1j$  along the imaginary axis to  $-\infty j$ .

`cmath.cos( $x$ )`

Return the cosine of  $x$ .

`cmath.sin( $x$ )`

Return the sine of  $x$ .

`cmath.tan( $x$ )`

Return the tangent of  $x$ .

## Hyperbolic functions

`cmath.acosh( $x$ )`

Return the inverse hyperbolic cosine of  $x$ . There is one branch cut, extending left from 1 along the real axis to  $-\infty$ .

`cmath.asinh( $x$ )`

Return the inverse hyperbolic sine of  $x$ . There are two branch cuts: One extends from  $1j$  along the imaginary axis to  $\infty j$ . The other extends from  $-1j$  along the imaginary axis to  $-\infty j$ .

`cmath.atanh(x)`

Return the inverse hyperbolic tangent of *x*. There are two branch cuts: One extends from 1 along the real axis to  $\infty$ . The other extends from  $-1$  along the real axis to  $-\infty$ .

`cmath.cosh(x)`

Return the hyperbolic cosine of *x*.

`cmath.sinh(x)`

Return the hyperbolic sine of *x*.

`cmath.tanh(x)`

Return the hyperbolic tangent of *x*.

## Classification functions

`cmath.isfinite(x)`

Return `True` if both the real and imaginary parts of *x* are finite, and `False` otherwise.

*New in version 3.2.*

`cmath.isinf(x)`

Return `True` if either the real or the imaginary part of *x* is an infinity, and `False` otherwise.

`cmath.isnan(x)`

Return `True` if either the real or the imaginary part of *x* is a NaN, and `False` otherwise.

`cmath.isclose(a, b, *, rel_tol=1e-09, abs_tol=0.0)`

Return `True` if the values *a* and *b* are close to each other and `False` otherwise.

Whether or not two values are considered close is determined

according to given absolute and relative tolerances.

*rel\_tol* is the relative tolerance – it is the maximum allowed difference between *a* and *b*, relative to the larger absolute value of *a* or *b*. For example, to set a tolerance of 5%, pass `rel_tol=0.05`. The default tolerance is `1e-09`, which assures that the two values are the same within about 9 decimal digits. *rel\_tol* must be greater than zero.

*abs\_tol* is the minimum absolute tolerance – useful for comparisons near zero. *abs\_tol* must be at least zero.

If no errors occur, the result will be: `abs(a-b) <= max(rel_tol * max(abs(a), abs(b)), abs_tol)`.

The IEEE 754 special values of `NaN`, `inf`, and `-inf` will be handled according to IEEE rules. Specifically, `NaN` is not considered close to any other value, including `NaN`. `inf` and `-inf` are only considered close to themselves.

*New in version 3.5.*

### See also

**PEP 485** [<https://peps.python.org/pep-0485/>] – A function for testing approximate equality

## Constants

`cmath.pi`

The mathematical constant  $\pi$ , as a float.

`cmath.e`

The mathematical constant *e*, as a float.

`cmath.tau`

The mathematical constant  $\tau$ , as a float.

*New in version 3.6.*

`cmath.inf`

Floating-point positive infinity. Equivalent to `float('inf')`.

*New in version 3.6.*

`cmath.infj`

Complex number with zero real part and positive infinity imaginary part. Equivalent to `complex(0.0, float('inf'))`.

*New in version 3.6.*

`cmath.nan`

A floating-point “not a number” (NaN) value. Equivalent to `float('nan')`.

*New in version 3.6.*

`cmath.nanj`

Complex number with zero real part and NaN imaginary part. Equivalent to `complex(0.0, float('nan'))`.

*New in version 3.6.*

Note that the selection of functions is similar, but not identical, to that in module `math`. The reason for having two modules is that some users aren’t interested in complex numbers, and perhaps don’t even know what they are. They would rather have `math.sqrt(-1)` raise an exception than return a complex number. Also note that the functions defined in `cmath` always return a complex number, even if the answer can be expressed as a real number (in which case the complex number has an imaginary part of zero).

A note on branch cuts: They are curves along which the given function fails to be continuous. They are a necessary feature of

many complex functions. It is assumed that if you need to compute with complex functions, you will understand about branch cuts. Consult almost any (not too elementary) book on complex variables for enlightenment. For information of the proper choice of branch cuts for numerical purposes, a good reference should be the following:

**See also**

Kahan, W: Branch cuts for complex elementary functions; or, Much ado about nothing's sign bit. In Iserles, A., and Powell, M. (eds.), *The state of the art in numerical analysis*. Clarendon Press (1987) pp165–211.

# decimal — Decimal fixed point and floating point arithmetic

Source code: [Lib/decimal.py](https://github.com/python/cpython/tree/3.11/Lib/decimal.py) [https://github.com/python/cpython/tree/3.11/Lib/decimal.py]

---

The `decimal` module provides support for fast correctly rounded decimal floating point arithmetic. It offers several advantages over the `float` datatype:

- Decimal “is based on a floating-point model which was designed with people in mind, and necessarily has a paramount guiding principle – computers must provide an arithmetic that works in the same way as the arithmetic that people learn at school.” – excerpt from the decimal arithmetic specification.
- Decimal numbers can be represented exactly. In contrast, numbers like `1.1` and `2.2` do not have exact representations in binary floating point. End users typically would not expect `1.1 + 2.2` to display as `3.3000000000000003` as it does with binary floating point.
- The exactness carries over into arithmetic. In decimal floating point, `0.1 + 0.1 + 0.1 - 0.3` is exactly equal to zero. In binary floating point, the result is `5.5511151231257827e-017`. While near to zero, the differences prevent reliable equality testing and differences can accumulate. For this reason, decimal is preferred in accounting applications which have strict equality invariants.
- The decimal module incorporates a notion of significant places so that `1.30 + 1.20` is `2.50`. The trailing zero is kept to indicate significance. This is the customary presentation for monetary applications. For multiplication,

the “schoolbook” approach uses all the figures in the multiplicands. For instance,  $1.3 * 1.2$  gives 1.56 while  $1.30 * 1.20$  gives 1.5600.

- Unlike hardware based binary floating point, the decimal module has a user alterable precision (defaulting to 28 places) which can be as large as needed for a given problem:

```
>>> from decimal import *
>>> getcontext().prec = 6
>>> Decimal(1) / Decimal(7)
Decimal('0.142857')
>>> getcontext().prec = 28
>>> Decimal(1) / Decimal(7)
Decimal('0.1428571428571428571428571428571429')
```

- Both binary and decimal floating point are implemented in terms of published standards. While the built-in float type exposes only a modest portion of its capabilities, the decimal module exposes all required parts of the standard. When needed, the programmer has full control over rounding and signal handling. This includes an option to enforce exact arithmetic by using exceptions to block any inexact operations.
- The decimal module was designed to support “without prejudice, both exact unrounded decimal arithmetic (sometimes called fixed-point arithmetic) and rounded floating-point arithmetic.” – excerpt from the decimal arithmetic specification.

The module design is centered around three concepts: the decimal number, the context for arithmetic, and signals.

A decimal number is immutable. It has a sign, coefficient digits, and an exponent. To preserve significance, the coefficient digits do not truncate trailing zeros. Decimals also include special values such as Infinity, -Infinity, and NaN. The standard also differentiates -0 from +0.

The context for arithmetic is an environment specifying precision,

rounding rules, limits on exponents, flags indicating the results of operations, and trap enablers which determine whether signals are treated as exceptions. Rounding options include `ROUND_CEILING`, `ROUND_DOWN`, `ROUND_FLOOR`, `ROUND_HALF_DOWN`, `ROUND_HALF_EVEN`, `ROUND_HALF_UP`, `ROUND_UP`, and `ROUND_05UP`.

Signals are groups of exceptional conditions arising during the course of computation. Depending on the needs of the application, signals may be ignored, considered as informational, or treated as exceptions. The signals in the decimal module are: `Clamped`, `InvalidOperation`, `DivisionByZero`, `Inexact`, `Rounded`, `Subnormal`, `Overflow`, `Underflow` and `FloatOperation`.

For each signal there is a flag and a trap enabler. When a signal is encountered, its flag is set to one, then, if the trap enabler is set to one, an exception is raised. Flags are sticky, so the user needs to reset them before monitoring a calculation.

## Quick-start Tutorial

The usual start to using decimals is importing the module, viewing the current context with `getcontext()` and, if necessary, setting new values for precision, rounding, or enabled traps:

```
>>> from decimal import *
>>> getcontext()
Context(prec=28, rounding=ROUND_HALF_EVEN, Emin=-999999,
        capitals=1, clamp=0, flags=[], traps=[Overflow,
        InvalidOperation])

>>> getcontext().prec = 7           # Set a new precision
```

Decimal instances can be constructed from integers, strings, floats, or tuples. Construction from an integer or a float performs an exact conversion of the value of that integer or float. Decimal numbers include special values such as NaN which stands for “Not a number”, positive and negative Infinity, and -0:

```
>>> getcontext().prec = 28
>>> Decimal(10)
Decimal('10')
>>> Decimal('3.14')
Decimal('3.14')
>>> Decimal(3.14)
Decimal('3.1400000000000000124344978758017532527446746826')
>>> Decimal((0, (3, 1, 4), -2))
Decimal('3.14')
>>> Decimal(str(2.0 ** 0.5))
Decimal('1.4142135623730951')
>>> Decimal(2) ** Decimal('0.5')
Decimal('1.414213562373095048801688724')
>>> Decimal('NaN')
Decimal('NaN')
>>> Decimal('-Infinity')
Decimal('-Infinity')
```

If the **FloatOperation** signal is trapped, accidental mixing of decimals and floats in constructors or ordering comparisons raises an exception:

```
>>> c = getcontext()
>>> c.traps[FloatOperation] = True
>>> Decimal(3.14)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: [<class 'decimal.FloatOperation'>]
>>> Decimal('3.5') < 3.7
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: [<class 'decimal.FloatOperation'>]
>>> Decimal('3.5') == 3.5
```

True

*New in version 3.3.*

The significance of a new Decimal is determined solely by the number of digits input. Context precision and rounding only come into play during arithmetic operations.

```
>>> getcontext().prec = 6
>>> Decimal('3.0')
Decimal('3.0')
>>> Decimal('3.1415926535')
Decimal('3.1415926535')
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85987')
>>> getcontext().rounding = ROUND_UP
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85988')
```

If the internal limits of the C version are exceeded, constructing a decimal raises `InvalidOperation`:

```
>>> Decimal("1e999999999999999999")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.InvalidOperation: [class 'decimal.InvalidOperat
```

*Changed in version 3.3.*

Decimals interact well with much of the rest of Python. Here is a small decimal floating point flying circus:

```
>>> data = list(map(Decimal, '1.34 1.87 3.45 2.35 1.00 0.03'.split()))
>>> max(data)
Decimal('9.25')
>>> min(data)
Decimal('0.03')
>>> sorted(data)
[Decimal('0.03'), Decimal('1.00'), Decimal('1.34'), Decimal('1.87'),
Decimal('2.35'), Decimal('3.45'), Decimal('9.25')]
```

```

>>> sum(data)
Decimal('19.29')
>>> a,b,c = data[:3]
>>> str(a)
'1.34'
>>> float(a)
1.34
>>> round(a, 1)
Decimal('1.3')
>>> int(a)
1
>>> a * 5
Decimal('6.70')
>>> a * b
Decimal('2.5058')
>>> c % a
Decimal('0.77')

```

And some mathematical functions are also available to Decimal:

```

>>> getcontext().prec = 28
>>> Decimal(2).sqrt()
Decimal('1.414213562373095048801688724')
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal('10').ln()
Decimal('2.302585092994045684017991455')
>>> Decimal('10').log10()
Decimal('1')

```

The **quantize()** method rounds a number to a fixed exponent. This method is useful for monetary applications that often round results to a fixed number of places:

```

>>> Decimal('7.325').quantize(Decimal('.01'), rounding=ROUND_FLOOR)
Decimal('7.32')
>>> Decimal('7.325').quantize(Decimal('1.'), rounding=ROUND_FLOOR)
Decimal('8')

```

As shown above, the **getcontext()** function accesses the current

context and allows the settings to be changed. This approach meets the needs of most applications.

For more advanced work, it may be useful to create alternate contexts using the `Context()` constructor. To make an alternate active, use the `setcontext()` function.

In accordance with the standard, the `decimal` module provides two ready to use standard contexts, `BasicContext` and `ExtendedContext`. The former is especially useful for debugging because many of the traps are enabled:

[illegible]

```
>>> ExtendedContext
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999,
       capitals=1, clamp=0, flags=[], traps=[])
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857143')
>>> Decimal(42) / Decimal(0)
Decimal('Infinity')
```

```
>>> setcontext(BasicContext)
>>> Decimal(42) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#143>", line 1, in -toplevel-
    Decimal(42) / Decimal(0)
DivisionByZero: x / 0
```

Contexts also have signal flags for monitoring exceptional conditions encountered during computations. The flags remain set until explicitly cleared, so it is best to clear the flags before each set of monitored computations by using the `clear_flags()` method.

```
>>> setcontext(ExtendedContext)
>>> getcontext().clear_flags()
```

```
>>> Decimal(355) / Decimal(113)
Decimal('3.14159292')
>>> getcontext()
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999,
        capitals=1, clamp=0, flags=[Inexact, Rounded], t
```

The *flags* entry shows that the rational approximation to pi was rounded (digits beyond the context precision were thrown away) and that the result is inexact (some of the discarded digits were non-zero).

Individual traps are set using the dictionary in the **traps** attribute of a context:

```
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(0)
Decimal('Infinity')
>>> getcontext().traps[DivisionByZero] = 1
>>> Decimal(1) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#112>", line 1, in -toplevel-
    Decimal(1) / Decimal(0)
DivisionByZero: x / 0
```

Most programs adjust the current context only once, at the beginning of the program. And, in many applications, data is converted to **Decimal** with a single cast inside a loop. With context set and decimals created, the bulk of the program manipulates the data no differently than with other Python numeric types.

## Decimal objects

*class decimal.Decimal(value = '0', context = None)*

Construct a new **Decimal** object based from *value*.

*value* can be an integer, string, tuple, **float**, or another **Decimal** object. If no *value* is given, returns

`Decimal('0')`. If *value* is a string, it should conform to the

decimal numeric string syntax after leading and trailing whitespace characters, as well as underscores throughout, are removed:

```
sign          ::= '+' | '-'
digit         ::= '0' | '1' | '2' | '3' | '4' |
indicator     ::= 'e' | 'E'
digits        ::= digit [digit]...
decimal-part  ::= digits '.' [digits] | ['.'] dig
exponent-part ::= indicator [sign] digits
infinity     ::= 'Infinity' | 'Inf'
nan          ::= 'NaN' [digits] | 'sNaN' [digits]
numeric-value ::= decimal-part [exponent-part] |
numeric-string ::= [sign] numeric-value | [sign] n
```

Other Unicode decimal digits are also permitted where `digit` appears above. These include decimal digits from various other alphabets (for example, Arabic-Indic and Devanāgarī digits) along with the fullwidth digits `'\uff10'` through `'\uff19'`.

If *value* is a **tuple**, it should have three components, a sign (0 for positive or 1 for negative), a **tuple** of digits, and an integer exponent. For example, `Decimal((0, (1, 4, 1, 4), -3))` returns `Decimal('1.414')`.

If *value* is a **float**, the binary floating point value is losslessly converted to its exact decimal equivalent. This conversion can often require 53 or more digits of precision. For example, `Decimal(float('1.1'))` converts to `Decimal('1.1000000000000000888178419700125232338905`

The *context* precision does not affect how many digits are stored. That is determined exclusively by the number of digits in *value*. For example, `Decimal('3.00000')` records all five zeros even if the context precision is only three.

The purpose of the *context* argument is determining what to do if *value* is a malformed string. If the context traps **InvalidOperation**, an exception is raised; otherwise, the constructor returns a new `Decimal` with the value of `NaN`.

Once constructed, `Decimal` objects are immutable.

*Changed in version 3.2:* The argument to the constructor is now permitted to be a `float` instance.

*Changed in version 3.3:* `float` arguments raise an exception if the `FloatOperation` trap is set. By default the trap is off.

*Changed in version 3.6:* Underscores are allowed for grouping, as with integral and floating-point literals in code.

Decimal floating point objects share many properties with the other built-in numeric types such as `float` and `int`. All of the usual math operations and special methods apply. Likewise, decimal objects can be copied, pickled, printed, used as dictionary keys, used as set elements, compared, sorted, and coerced to another type (such as `float` or `int`).

There are some small differences between arithmetic on Decimal objects and arithmetic on integers and floats. When the remainder operator `%` is applied to Decimal objects, the sign of the result is the sign of the *dividend* rather than the sign of the divisor:

```
>>> (-7) % 4
1
>>> Decimal(-7) % Decimal(4)
Decimal('-3')
```

The integer division operator `//` behaves analogously, returning the integer part of the true quotient (truncating towards zero) rather than its floor, so as to preserve the usual identity `x == (x // y) * y + x % y`:

```
>>> -7 // 4
-2
>>> Decimal(-7) // Decimal(4)
Decimal('-1')
```

The `%` and `//` operators implement the remainder and divide-integer operations (respectively) as described in

the specification.

Decimal objects cannot generally be combined with floats or instances of `fractions.Fraction` in arithmetic operations: an attempt to add a `Decimal` to a `float`, for example, will raise a `TypeError`. However, it is possible to use Python's comparison operators to compare a `Decimal` instance `x` with another number `y`. This avoids confusing results when doing equality comparisons between numbers of different types.

*Changed in version 3.2:* Mixed-type comparisons between `Decimal` instances and other numeric types are now fully supported.

In addition to the standard numeric properties, decimal floating point objects also have a number of specialized methods:

`adjusted()`

Return the adjusted exponent after shifting out the coefficient's rightmost digits until only the lead digit remains: `Decimal('321e+5').adjusted()` returns seven. Used for determining the position of the most significant digit with respect to the decimal point.

`as_integer_ratio()`

Return a pair `(n, d)` of integers that represent the given `Decimal` instance as a fraction, in lowest terms and with a positive denominator:

```
>>> Decimal('-3.14').as_integer_ratio()
(-157, 50)
```

The conversion is exact. Raise `OverflowError` on infinities and `ValueError` on NaNs.

*New in version 3.6.*

`as_tuple()`

Return a **named tuple** representation of the number:  
`DecimalTuple(sign, digits, exponent)`.

### `canonical()`

Return the canonical encoding of the argument.  
Currently, the encoding of a **Decimal** instance is always canonical, so this operation returns its argument unchanged.

### `compare(other, context=None)`

Compare the values of two Decimal instances.  
**compare()** returns a Decimal instance, and if either operand is a NaN then the result is a NaN:

```
a or b is a NaN    ==> Decimal('NaN')
a < b              ==> Decimal('-1')
a == b             ==> Decimal('0')
a > b              ==> Decimal('1')
```

### `compare_signal(other, context=None)`

This operation is identical to the **compare()** method, except that all NaNs signal. That is, if neither operand is a signaling NaN then any quiet NaN operand is treated as though it were a signaling NaN.

### `compare_total(other, context=None)`

Compare two operands using their abstract representation rather than their numerical value.  
Similar to the **compare()** method, but the result gives a total ordering on **Decimal** instances. Two **Decimal** instances with the same numeric value but different representations compare unequal in this ordering:

```
>>> Decimal('12.0').compare_total(Decimal('12'))
Decimal('-1')
```

Quiet and signaling NaNs are also included in the total ordering. The result of this function is `Decimal('0')`

if both operands have the same representation, `Decimal('-1')` if the first operand is lower in the total order than the second, and `Decimal('1')` if the first operand is higher in the total order than the second operand. See the specification for details of the total order.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

`compare_total_mag(other, context=None)`

Compare two operands using their abstract representation rather than their value as in `compare_total()`, but ignoring the sign of each operand. `x.compare_total_mag(y)` is equivalent to `x.copy_abs().compare_total(y.copy_abs())`.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

`conjugate()`

Just returns self, this method is only to comply with the Decimal Specification.

`copy_abs()`

Return the absolute value of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

`copy_negate()`

Return the negation of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

`copy_sign(other, context=None)`

Return a copy of the first operand with the sign set to be the same as the sign of the second operand. For example:

```
>>> Decimal('2.3').copy_sign(Decimal('-1.5'))
Decimal('-2.3')
```

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

`exp(context=None)`

Return the value of the (natural) exponential function  $e^{**x}$  at the given number. The result is correctly rounded using the `ROUND_HALF_EVEN` rounding mode.

```
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal(321).exp()
Decimal('2.561702493119680037517373933E+139')
```

*classmethod* `from_float(f)`

Alternative constructor that only accepts instances of `float` or `int`.

**Note** `Decimal.from_float(0.1)` is not the same as `Decimal('0.1')`. Since 0.1 is not exactly representable in binary floating point, the value is stored as the nearest representable value which is  $0 \times 1.9999999999999999 \text{ap-4}$ . That equivalent value in decimal is

0.10000000000000000005551115123125782702118158340

### Note

From Python 3.2 onwards, a `Decimal` instance can

also be constructed directly from a **float**.

```
>>> Decimal.from_float(0.1)
Decimal('0.100000000000000005551115123125782702')
>>> Decimal.from_float(float('nan'))
Decimal('NaN')
>>> Decimal.from_float(float('inf'))
Decimal('Infinity')
>>> Decimal.from_float(float('-inf'))
Decimal('-Infinity')
```

*New in version 3.1.*

**fma**(*other, third, context=None*)

Fused multiply-add. Return  $\text{self} * \text{other} + \text{third}$  with no rounding of the intermediate product  $\text{self} * \text{other}$ .

```
>>> Decimal(2).fma(3, 5)
Decimal('11')
```

**is\_canonical**()

Return **True** if the argument is canonical and **False** otherwise. Currently, a **Decimal** instance is always canonical, so this operation always returns **True**.

**is\_finite**()

Return **True** if the argument is a finite number, and **False** if the argument is an infinity or a NaN.

**is\_infinite**()

Return **True** if the argument is either positive or negative infinity and **False** otherwise.

**is\_nan**()

Return **True** if the argument is a (quiet or signaling) NaN and **False** otherwise.

`is_normal(context=None)`

Return **True** if the argument is a *normal* finite number.  
Return **False** if the argument is zero, subnormal, infinite or a NaN.

`is_qnan()`

Return **True** if the argument is a quiet NaN, and **False** otherwise.

`is_signed()`

Return **True** if the argument has a negative sign and **False** otherwise. Note that zeros and NaNs can both carry signs.

`is_snan()`

Return **True** if the argument is a signaling NaN and **False** otherwise.

`is_subnormal(context=None)`

Return **True** if the argument is subnormal, and **False** otherwise.

`is_zero()`

Return **True** if the argument is a (positive or negative) zero and **False** otherwise.

`ln(context=None)`

Return the natural (base e) logarithm of the operand.  
The result is correctly rounded using the **ROUND\_HALF\_EVEN** rounding mode.

`log10(context=None)`

Return the base ten logarithm of the operand. The result is correctly rounded using the **ROUND\_HALF\_EVEN** rounding mode.

`logb(context=None)`

For a nonzero number, return the adjusted exponent of its operand as a `Decimal` instance. If the operand is a zero then `Decimal('-Infinity')` is returned and the `DivisionByZero` flag is raised. If the operand is an infinity then `Decimal('Infinity')` is returned.

`logical_and(other, context=None)`

`logical_and()` is a logical operation which takes two *logical operands* (see [Logical operands](#)). The result is the digit-wise `and` of the two operands.

`logical_invert(context=None)`

`logical_invert()` is a logical operation. The result is the digit-wise inversion of the operand.

`logical_or(other, context=None)`

`logical_or()` is a logical operation which takes two *logical operands* (see [Logical operands](#)). The result is the digit-wise `or` of the two operands.

`logical_xor(other, context=None)`

`logical_xor()` is a logical operation which takes two *logical operands* (see [Logical operands](#)). The result is the digit-wise exclusive or of the two operands.

`max(other, context=None)`

Like `max(self, other)` except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

`max_mag(other, context=None)`

Similar to the `max()` method, but the comparison is done using the absolute values of the operands.

`min(other, context=None)`

Like `min(self, other)` except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

`min_mag(other, context=None)`

Similar to the `min()` method, but the comparison is done using the absolute values of the operands.

`next_minus(context=None)`

Return the largest number representable in the given context (or in the current thread's context if no context is given) that is smaller than the given operand.

`next_plus(context=None)`

Return the smallest number representable in the given context (or in the current thread's context if no context is given) that is larger than the given operand.

`next_toward(other, context=None)`

If the two operands are unequal, return the number closest to the first operand in the direction of the second operand. If both operands are numerically equal, return a copy of the first operand with the sign set to be the same as the sign of the second operand.

`normalize(context=None)`

Used for producing canonical values of an equivalence class within either the current context or the specified context.

This has the same semantics as the unary plus operation, except that if the final result is finite it is reduced to its simplest form, with all trailing zeros removed and its sign preserved. That is, while the coefficient is non-zero and a multiple of ten the

coefficient is divided by ten and the exponent is incremented by 1. Otherwise (the coefficient is zero) the exponent is set to 0. In all cases the sign is unchanged.

For example, `Decimal('32.100')` and `Decimal('0.321000e+2')` both normalize to the equivalent value `Decimal('32.1')`.

Note that rounding is applied *before* reducing to simplest form.

In the latest versions of the specification, this operation is also known as `reduce`.

`number_class(context=None)`

Return a string describing the *class* of the operand. The returned value is one of the following ten strings.

- `"-Infinity"`, indicating that the operand is negative infinity.
- `"-Normal"`, indicating that the operand is a negative normal number.
- `"-Subnormal"`, indicating that the operand is negative and subnormal.
- `"-Zero"`, indicating that the operand is a negative zero.
- `"+Zero"`, indicating that the operand is a positive zero.
- `"+Subnormal"`, indicating that the operand is positive and subnormal.
- `"+Normal"`, indicating that the operand is a positive normal number.
- `"+Infinity"`, indicating that the operand is positive infinity.
- `"NaN"`, indicating that the operand is a quiet NaN (Not a Number).
- `"sNaN"`, indicating that the operand is a signaling NaN.

`quantize(exp, rounding=None, context=None)`

Return a value equal to the first operand after rounding and having the exponent of the second operand.

```
>>> Decimal('1.41421356').quantize(Decimal('1.0'))
Decimal('1.414')
```

Unlike other operations, if the length of the coefficient after the quantize operation would be greater than precision, then an **InvalidOperation** is signaled. This guarantees that, unless there is an error condition, the quantized exponent is always equal to that of the right-hand operand.

Also unlike other operations, quantize never signals Underflow, even if the result is subnormal and inexact.

If the exponent of the second operand is larger than that of the first then rounding may be necessary. In this case, the rounding mode is determined by the `rounding` argument if given, else by the given `context` argument; if neither argument is given the rounding mode of the current thread's context is used.

An error is returned whenever the resulting exponent is greater than **E<sub>max</sub>** or less than **E<sub>tiny</sub>**( ).

`radix()`

Return `Decimal(10)`, the radix (base) in which the **Decimal** class does all its arithmetic. Included for compatibility with the specification.

`remainder_near(other, context=None)`

Return the remainder from dividing *self* by *other*. This differs from `self % other` in that the sign of the remainder is chosen so as to minimize its absolute value. More precisely, the return value is `self - n * other` where `n` is the integer nearest to the exact value of `self / other`, and if two integers are

equally near then the even one is chosen.

If the result is zero then its sign will be the sign of *self*.

```
>>> Decimal(18).remainder_near(Decimal(10))
Decimal('-2')
>>> Decimal(25).remainder_near(Decimal(10))
Decimal('5')
>>> Decimal(35).remainder_near(Decimal(10))
Decimal('-5')
```

**rotate(*other*, *context*=None)**

Return the result of rotating the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range -precision through precision. The absolute value of the second operand gives the number of places to rotate. If the second operand is positive then rotation is to the left; otherwise rotation is to the right. The coefficient of the first operand is padded on the left with zeros to length precision if necessary. The sign and exponent of the first operand are unchanged.

**same\_quantum(*other*, *context*=None)**

Test whether self and other have the same exponent or whether both are NaN.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

**scaleb(*other*, *context*=None)**

Return the first operand with exponent adjusted by the second. Equivalently, return the first operand multiplied by  $10^{**other}$ . The second operand must be an integer.

`shift(other, context=None)`

Return the result of shifting the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range -precision through precision. The absolute value of the second operand gives the number of places to shift. If the second operand is positive then the shift is to the left; otherwise the shift is to the right. Digits shifted into the coefficient are zeros. The sign and exponent of the first operand are unchanged.

`sqrt(context=None)`

Return the square root of the argument to full precision.

`to_eng_string(context=None)`

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

For example, this converts `Decimal('123E+1')` to `Decimal('1.23E+3')`.

`to_integral(rounding=None, context=None)`

Identical to the `to_integral_value()` method. The `to_integral` name has been kept for compatibility with older versions.

`to_integral_exact(rounding=None, context=None)`

Round to the nearest integer, signaling **Inexact** or **Rounded** as appropriate if rounding occurs. The rounding mode is determined by the `rounding` parameter if given, else by the given `context`. If neither parameter is given then the rounding mode of

the current context is used.

`to_integral_value(rounding=None, context=None)`

Round to the nearest integer without signaling **Inexact** or **Rounded**. If given, applies *rounding*; otherwise, uses the rounding method in either the supplied *context* or the current context.

## Logical operands

The `logical_and()`, `logical_invert()`, `logical_or()`, and `logical_xor()` methods expect their arguments to be *logical operands*. A *logical operand* is a **Decimal** instance whose exponent and sign are both zero, and whose digits are all either 0 or 1.

## Context objects

Contexts are environments for arithmetic operations. They govern precision, set rules for rounding, determine which signals are treated as exceptions, and limit the range for exponents.

Each thread has its own current context which is accessed or changed using the `getcontext()` and `setcontext()` functions:

`decimal.getcontext()`

Return the current context for the active thread.

`decimal.setcontext(c)`

Set the current context for the active thread to *c*.

You can also use the **with** statement and the `localcontext()` function to temporarily change the active context.

`decimal.localcontext(ctx=None, **kwargs)`

Return a context manager that will set the current context for the active thread to a copy of *ctx* on entry to the with-statement and restore the previous context when exiting the

with-statement. If no context is specified, a copy of the current context is used. The *kwargs* argument is used to set the attributes of the new context.

For example, the following code sets the current decimal precision to 42 places, performs a calculation, and then automatically restores the previous context:

```
from decimal import localcontext

with localcontext() as ctx:
    ctx.prec = 42    # Perform a high precision calc
    s = calculate_something()
s = +s    # Round the final result back to the default
```

Using keyword arguments, the code would be the following:

```
from decimal import localcontext

with localcontext(prec=42) as ctx:
    s = calculate_something()
s = +s
```

Raises **TypeError** if *kwargs* supplies an attribute that **Context** doesn't support. Raises either **TypeError** or **ValueError** if *kwargs* supplies an invalid value for an attribute.

*Changed in version 3.11:* **localcontext()** now supports setting context attributes through the use of keyword arguments.

New contexts can also be created using the **Context** constructor described below. In addition, the module provides three pre-made contexts:

*class* decimal.BasicContext

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to **ROUND\_HALF\_UP**. All flags are cleared. All traps are

enabled (treated as exceptions) except `Inexact`, `Rounded`, and `Subnormal`.

Because many of the traps are enabled, this context is useful for debugging.

*class* `decimal.ExtendedContext`

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to `ROUND_HALF_EVEN`. All flags are cleared. No traps are enabled (so that exceptions are not raised during computations).

Because the traps are disabled, this context is useful for applications that prefer to have result value of `NaN` or `Infinity` instead of raising exceptions. This allows an application to complete a run in the presence of conditions that would otherwise halt the program.

*class* `decimal.DefaultContext`

This context is used by the `Context` constructor as a prototype for new contexts. Changing a field (such a precision) has the effect of changing the default for new contexts created by the `Context` constructor.

This context is most useful in multi-threaded environments. Changing one of the fields before threads are started has the effect of setting system-wide defaults. Changing the fields after threads have started is not recommended as it would require thread synchronization to prevent race conditions.

In single threaded environments, it is preferable to not use this context at all. Instead, simply create contexts explicitly as described below.

The default values are `Context.prec=28`, `Context.rounding=ROUND_HALF_EVEN`, and enabled traps for `Overflow`, `InvalidOperation`, and `DivisionByZero`.

In addition to the three supplied contexts, new contexts can be created with the **Context** constructor.

```
class decimal.Context(prec=None, rounding=None, Emin=None,
Emax=None, capitals=None, clamp=None, flags=None,
traps=None)
```

Creates a new context. If a field is not specified or is **None**, the default values are copied from the **DefaultContext**. If the *flags* field is not specified or is **None**, all flags are cleared.

The *prec* is an integer in the range [1, **MAX\_PREC**] that sets the precision for arithmetic operations in the context.

The *rounding* option is one of the constants listed in the section **Rounding Modes**.

The *traps* and *flags* fields list any signals to be set. Generally, new contexts should only set traps and leave the flags clear.

The *Emin* and *Emax* fields are integers specifying the outer limits allowable for exponents. *Emin* must be in the range [**MIN\_EMIN**, 0], *Emax* in the range [0, **MAX\_EMAX**].

The *capitals* field is either 0 or 1 (the default). If set to 1, exponents are printed with a capital E; otherwise, a lowercase e is used: `Decimal('6.02e+23')`.

The *clamp* field is either 0 (the default) or 1. If set to 1, the exponent *e* of a **Decimal** instance representable in this context is strictly limited to the range  $E_{min} - prec + 1 \leq e \leq E_{max} - prec + 1$ . If *clamp* is 0 then a weaker condition holds: the adjusted exponent of the **Decimal** instance is at most **E<sub>max</sub>**. When *clamp* is 1, a large normal number will, where possible, have its exponent reduced and a corresponding number of zeros added to its coefficient, in order to fit the exponent constraints; this preserves the value of the number but loses information about significant trailing zeros. For example:

```
>>> Context(prec=6, Emax=999, clamp=1).create_decimal(
Decimal('1.23000E+999'))
```

A *clamp* value of 1 allows compatibility with the fixed-width decimal interchange formats specified in IEEE 754.

The **Context** class defines several general purpose methods as well as a large number of methods for doing arithmetic directly in a given context. In addition, for each of the **Decimal** methods described above (with the exception of the **adjusted()** and **as\_tuple()** methods) there is a corresponding **Context** method. For example, for a **Context** instance `C` and **Decimal** instance `x`, `C.exp(x)` is equivalent to `x.exp(context=C)`. Each **Context** method accepts a Python integer (an instance of **int**) anywhere that a **Decimal** instance is accepted.

`clear_flags()`

Resets all of the flags to 0.

`clear_traps()`

Resets all of the traps to 0.

*New in version 3.3.*

`copy()`

Return a duplicate of the context.

`copy_decimal(num)`

Return a copy of the **Decimal** instance `num`.

`create_decimal(num)`

Creates a new **Decimal** instance from `num` but using *self* as context. Unlike the **Decimal** constructor, the context precision, rounding method, flags, and traps are applied to the conversion.

This is useful because constants are often given to a greater precision than is needed by the application. Another benefit is that rounding immediately eliminates unintended effects from digits beyond the

current precision. In the following example, using unrounded inputs means that adding zero to a sum can change the result:

```
>>> getcontext().prec = 3
>>> Decimal('3.4445') + Decimal('1.0023')
Decimal('4.45')
>>> Decimal('3.4445') + Decimal(0) + Decimal('1')
Decimal('4.44')
```

This method implements the to-number operation of the IBM specification. If the argument is a string, no leading or trailing whitespace or underscores are permitted.

### `create_decimal_from_float(f)`

Creates a new Decimal instance from a float *f* but rounding using *self* as the context. Unlike the `Decimal.from_float()` class method, the context precision, rounding method, flags, and traps are applied to the conversion.

```
>>> context = Context(prec=5, rounding=ROUND_DOWN)
>>> context.create_decimal_from_float(math.pi)
Decimal('3.1415')
>>> context = Context(prec=5, traps=[Inexact])
>>> context.create_decimal_from_float(math.pi)
Traceback (most recent call last):
...
decimal.Inexact: None
```

*New in version 3.1.*

### `Etiny()`

Returns a value equal to `Emin - prec + 1` which is the minimum exponent value for subnormal results.

When underflow occurs, the exponent is set to `Etiny`.

### `Etop()`

Returns a value equal to  $E_{\max} - \text{prec} + 1$ .

The usual approach to working with decimals is to create **Decimal** instances and then apply arithmetic operations which take place within the current context for the active thread. An alternative approach is to use context methods for calculating within a specific context. The methods are similar to those for the **Decimal** class and are only briefly recounted here.

`abs(x)`

Returns the absolute value of  $x$ .

`add(x, y)`

Return the sum of  $x$  and  $y$ .

`canonical(x)`

Returns the same Decimal object  $x$ .

`compare(x, y)`

Compares  $x$  and  $y$  numerically.

`compare_signal(x, y)`

Compares the values of the two operands numerically.

`compare_total(x, y)`

Compares two operands using their abstract representation.

`compare_total_mag(x, y)`

Compares two operands using their abstract representation, ignoring sign.

`copy_abs(x)`

Returns a copy of  $x$  with the sign set to 0.

`copy_negate(x)`

Returns a copy of  $x$  with the sign inverted.

`copy_sign(x, y)`

Copies the sign from  $y$  to  $x$ .

`divide(x, y)`

Return  $x$  divided by  $y$ .

`divide_int(x, y)`

Return  $x$  divided by  $y$ , truncated to an integer.

`divmod(x, y)`

Divides two numbers and returns the integer part of the result.

`exp(x)`

Returns  $e^{**} x$ .

`fma(x, y, z)`

Returns  $x$  multiplied by  $y$ , plus  $z$ .

`is_canonical(x)`

Returns `True` if  $x$  is canonical; otherwise returns `False`.

`is_finite(x)`

Returns `True` if  $x$  is finite; otherwise returns `False`.

`is_infinite(x)`

Returns `True` if  $x$  is infinite; otherwise returns `False`.

`is_nan(x)`

Returns `True` if  $x$  is a qNaN or sNaN; otherwise

returns False.

`is_normal(x)`

Returns True if  $x$  is a normal number; otherwise returns False.

`is_qnan(x)`

Returns True if  $x$  is a quiet NaN; otherwise returns False.

`is_signed(x)`

Returns True if  $x$  is negative; otherwise returns False.

`is_snan(x)`

Returns True if  $x$  is a signaling NaN; otherwise returns False.

`is_subnormal(x)`

Returns True if  $x$  is subnormal; otherwise returns False.

`is_zero(x)`

Returns True if  $x$  is a zero; otherwise returns False.

`ln(x)`

Returns the natural (base  $e$ ) logarithm of  $x$ .

`log10(x)`

Returns the base 10 logarithm of  $x$ .

`logb(x)`

Returns the exponent of the magnitude of the operand's MSD.

`logical_and(x, y)`

Applies the logical operation *and* between each operand's digits.

`logical_invert(x)`

Invert all the digits in *x*.

`logical_or(x, y)`

Applies the logical operation *or* between each operand's digits.

`logical_xor(x, y)`

Applies the logical operation *xor* between each operand's digits.

`max(x, y)`

Compares two values numerically and returns the maximum.

`max_mag(x, y)`

Compares the values numerically with their sign ignored.

`min(x, y)`

Compares two values numerically and returns the minimum.

`min_mag(x, y)`

Compares the values numerically with their sign ignored.

`minus(x)`

Minus corresponds to the unary prefix minus operator in Python.

`multiply(x, y)`

Return the product of  $x$  and  $y$ .

`next_minus(x)`

Returns the largest representable number smaller than  $x$ .

`next_plus(x)`

Returns the smallest representable number larger than  $x$ .

`next_toward(x, y)`

Returns the number closest to  $x$ , in direction towards  $y$ .

`normalize(x)`

Reduces  $x$  to its simplest form.

`number_class(x)`

Returns an indication of the class of  $x$ .

`plus(x)`

Plus corresponds to the unary prefix plus operator in Python. This operation applies the context precision and rounding, so it is *not* an identity operation.

`power(x, y, modulo=None)`

Return  $x$  to the power of  $y$ , reduced modulo `modulo` if given.

With two arguments, compute  $x^{**}y$ . If  $x$  is negative then  $y$  must be integral. The result will be inexact unless  $y$  is integral and the result is finite and can be expressed exactly in 'precision' digits. The rounding mode of the context is used. Results are always correctly rounded in the Python version.

`Decimal(0) ** Decimal(0)` results in `InvalidOperation`, and if `InvalidOperation` is not trapped, then results in `Decimal('NaN')`.

*Changed in version 3.3:* The C module computes `power()` in terms of the correctly rounded `exp()` and `ln()` functions. The result is well-defined but only “almost always correctly rounded”.

With three arguments, compute `(x**y) % modulo`. For the three argument form, the following restrictions on the arguments hold:

- all three arguments must be integral
- `y` must be nonnegative
- at least one of `x` or `y` must be nonzero
- `modulo` must be nonzero and have at most ‘precision’ digits

The value resulting from `Context.power(x, y, modulo)` is equal to the value that would be obtained by computing `(x**y) % modulo` with unbounded precision, but is computed more efficiently. The exponent of the result is zero, regardless of the exponents of `x`, `y` and `modulo`. The result is always exact.

`quantize(x, y)`

Returns a value equal to `x` (rounded), having the exponent of `y`.

`radix()`

Just returns 10, as this is Decimal, :)

`remainder(x, y)`

Returns the remainder from integer division.

The sign of the result, if non-zero, is the same as that of the original dividend.

`remainder_near(x, y)`

Returns  $x - y * n$ , where  $n$  is the integer nearest the exact value of  $x / y$  (if the result is 0 then its sign will be the sign of  $x$ ).

`rotate(x, y)`

Returns a rotated copy of  $x$ ,  $y$  times.

`same_quantum(x, y)`

Returns `True` if the two operands have the same exponent.

`scaleb(x, y)`

Returns the first operand after adding the second value its exp.

`shift(x, y)`

Returns a shifted copy of  $x$ ,  $y$  times.

`sqrt(x)`

Square root of a non-negative number to context precision.

`subtract(x, y)`

Return the difference between  $x$  and  $y$ .

`to_eng_string(x)`

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of

either one or two trailing zeros.

`to_integral_exact(x)`

Rounds to an integer.

`to_sci_string(x)`

Converts a number to a string using scientific notation.

## Constants

The constants in this section are only relevant for the C module. They are also included in the pure Python version for compatibility.

---

### 64-bit

---

`decimal.DECIMAL_MAX_PREC` 999

---

`decimal.DECIMAL_MAX_FMAX` 999

---

`decimal.DECIMAL_MIN` 99999

---

`decimal.DECIMAL_ETINY` 99997

---

`decimal.HAVE_THREADS`

The value is `True`. Deprecated, because Python now always has threads.

*Deprecated since version 3.9.*

`decimal.HAVE_CONTEXTVAR`

The default value is `True`. If Python is **configured using the `--without-decimal-contextvar` option**, the C version uses a thread-local rather than a coroutine-local context and the value is `False`. This is slightly faster in some nested context scenarios.

*New in version 3.9:* backported to 3.7 and 3.8.

## Rounding modes

`decimal.ROUND_CEILING`

Round towards `Infinity`.

`decimal.ROUND_DOWN`

Round towards zero.

`decimal.ROUND_FLOOR`

Round towards `-Infinity`.

`decimal.ROUND_HALF_DOWN`

Round to nearest with ties going towards zero.

`decimal.ROUND_HALF_EVEN`

Round to nearest with ties going to nearest even integer.

`decimal.ROUND_HALF_UP`

Round to nearest with ties going away from zero.

`decimal.ROUND_UP`

Round away from zero.

`decimal.ROUND_05UP`

Round away from zero if last digit after rounding towards zero would have been 0 or 5; otherwise round towards zero.

## Signals

Signals represent conditions that arise during computation. Each corresponds to one context flag and one context trap enabler.

The context flag is set whenever the condition is encountered. After the computation, flags may be checked for informational purposes (for instance, to determine whether a computation was exact). After checking the flags, be sure to clear all flags before starting the next computation.

If the context's trap enabler is set for the signal, then the condition causes a Python exception to be raised. For example, if the

**DivisionByZero** trap is set, then a **DivisionByZero** exception is raised upon encountering the condition.

*class* decimal.Clamped

Altered an exponent to fit representation constraints.

Typically, clamping occurs when an exponent falls outside the context's **Emin** and **Emax** limits. If possible, the exponent is reduced to fit by adding zeros to the coefficient.

*class* decimal.DecimalException

Base class for other signals and a subclass of **ArithmeticError**.

*class* decimal.DivisionByZero

Signals the division of a non-infinite number by zero.

Can occur with division, modulo division, or when raising a number to a negative power. If this signal is not trapped, returns `Infinity` or `-Infinity` with the sign determined by the inputs to the calculation.

*class* decimal.Inexact

Indicates that rounding occurred and the result is not exact.

Signals when non-zero digits were discarded during rounding. The rounded result is returned. The signal flag or trap is used to detect when results are inexact.

*class* decimal.InvalidOperation

An invalid operation was performed.

Indicates that an operation was requested that does not make sense. If not trapped, returns `NaN`. Possible causes include:

```
Infinity - Infinity
0 * Infinity
Infinity / Infinity
x % 0
```

```
Infinity % x
sqrt(-x) and x > 0
0 ** 0
x ** (non-integer)
x ** Infinity
```

### *class* decimal.Overflow

Numerical overflow.

Indicates the exponent is larger than **Context.Emax** after rounding has occurred. If not trapped, the result depends on the rounding mode, either pulling inward to the largest representable finite number or rounding outward to **Infinity**. In either case, **Inexact** and **Rounded** are also signaled.

### *class* decimal.Rounded

Rounding occurred though possibly no information was lost.

Signaled whenever rounding discards digits; even if those digits are zero (such as rounding 5.00 to 5.0). If not trapped, returns the result unchanged. This signal is used to detect loss of significant digits.

### *class* decimal.Subnormal

Exponent was lower than **Emin** prior to rounding.

Occurs when an operation result is subnormal (the exponent is too small). If not trapped, returns the result unchanged.

### *class* decimal.Underflow

Numerical underflow with result rounded to zero.

Occurs when a subnormal result is pushed to zero by rounding. **Inexact** and **Subnormal** are also signaled.

### *class* decimal.FloatOperation

Enable stricter semantics for mixing floats and Decimals.

If the signal is not trapped (default), mixing floats and Decimals is permitted in the `Decimal` constructor, `create_decimal()` and all comparison operators. Both conversion and comparisons are exact. Any occurrence of a mixed operation is silently recorded by setting `FloatOperation` in the context flags. Explicit conversions with `from_float()` or `create_decimal_from_float()` do not set the flag.

Otherwise (the signal is trapped), only equality comparisons and explicit conversions are silent. All other mixed operations raise `FloatOperation`.

The following table summarizes the hierarchy of signals:

```
exceptions.ArithmeticError(exceptions.Exception)
    DecimalException
        Clamped
        DivisionByZero(DecimalException, exceptions.ZeroDivisionError)
        Inexact
            Overflow(Inexact, Rounded)
            Underflow(Inexact, Rounded, Subnormal)
        InvalidOperation
        Rounded
        Subnormal
        FloatOperation(DecimalException, exceptions.TypeError)
```

## Floating Point Notes

### Mitigating round-off error with increased precision

The use of decimal floating point eliminates decimal representation error (making it possible to represent `0.1` exactly); however, some operations can still incur round-off error when non-zero digits exceed the fixed precision.

The effects of round-off error can be amplified by the addition or subtraction of nearly offsetting quantities resulting in loss of significance. Knuth provides two instructive examples where

rounded floating point arithmetic with insufficient precision causes the breakdown of the associative and distributive properties of addition:

```
# Examples from Seminumerical Algorithms, Section 4.2.2.
>>> from decimal import Decimal, getcontext
>>> getcontext().prec = 8

>>> u, v, w = Decimal(11111113), Decimal(-11111111), Dec
>>> (u + v) + w
Decimal('9.5111111')
>>> u + (v + w)
Decimal('10')
```

```
>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.00
>>> (u*v) + (u*w)
Decimal('0.01')
>>> u * (v+w)
Decimal('0.0060000')
```

The **decimal** module makes it possible to restore the identities by expanding the precision sufficiently to avoid loss of significance:

```
>>> getcontext().prec = 20
>>> u, v, w = Decimal(11111113), Decimal(-11111111), Dec
>>> (u + v) + w
Decimal('9.51111111')
>>> u + (v + w)
Decimal('9.51111111')
>>>

>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.00
>>> (u*v) + (u*w)
Decimal('0.0060000')
>>> u * (v+w)
Decimal('0.0060000')
```

## Special values

The number system for the **decimal** module provides special

values including NaN, sNaN, -Infinity, Infinity, and two zeros, +0 and -0.

Infinities can be constructed directly with:

`Decimal('Infinity')`. Also, they can arise from dividing by zero when the **DivisionByZero** signal is not trapped. Likewise, when the **Overflow** signal is not trapped, infinity can result from rounding beyond the limits of the largest representable number.

The infinities are signed (affine) and can be used in arithmetic operations where they get treated as very large, indeterminate numbers. For instance, adding a constant to infinity gives another infinite result.

Some operations are indeterminate and return NaN, or if the **InvalidOperation** signal is trapped, raise an exception. For example, `0/0` returns NaN which means “not a number”. This variety of NaN is quiet and, once created, will flow through other computations always resulting in another NaN. This behavior can be useful for a series of computations that occasionally have missing inputs — it allows the calculation to proceed while flagging specific results as invalid.

A variant is sNaN which signals rather than remaining quiet after every operation. This is a useful return value when an invalid result needs to interrupt a calculation for special handling.

The behavior of Python’s comparison operators can be a little surprising where a NaN is involved. A test for equality where one of the operands is a quiet or signaling NaN always returns **False** (even when doing `Decimal('NaN')==Decimal('NaN')`), while a test for inequality always returns **True**. An attempt to compare two Decimals using any of the `<`, `<=`, `>` or `>=` operators will raise the **InvalidOperation** signal if either operand is a NaN, and return **False** if this signal is not trapped. Note that the General Decimal Arithmetic specification does not specify the behavior of direct comparisons; these rules for comparisons involving a NaN were taken from the IEEE 854 standard (see Table 3 in section 5.7). To ensure strict standards-compliance, use the **compare()** and **compare\_signal()** methods instead.

The signed zeros can result from calculations that underflow. They keep the sign that would have resulted if the calculation had been carried out to greater precision. Since their magnitude is zero, both positive and negative zeros are treated as equal and their sign is informational.

In addition to the two signed zeros which are distinct yet equal, there are various representations of zero with differing precisions yet equivalent in value. This takes a bit of getting used to. For an eye accustomed to normalized floating point representations, it is not immediately obvious that the following calculation returns a value equal to zero:

```
>>> 1 / Decimal('Infinity')
Decimal('0E-1000026')
```

## Working with threads

The `getcontext()` function accesses a different `Context` object for each thread. Having separate thread contexts means that threads may make changes (such as `getcontext().prec=10`) without interfering with other threads.

Likewise, the `setcontext()` function automatically assigns its target to the current thread.

If `setcontext()` has not been called before `getcontext()`, then `getcontext()` will automatically create a new context for use in the current thread.

The new context is copied from a prototype context called *DefaultContext*. To control the defaults so that each thread will use the same values throughout the application, directly modify the *DefaultContext* object. This should be done *before* any threads are started so that there won't be a race condition between threads calling `getcontext()`. For example:

```
# Set applicationwide defaults for all threads about to
DefaultContext.prec = 12
DefaultContext.rounding = ROUND_DOWN
```

```
DefaultContext.traps = ExtendedContext.traps.copy()
DefaultContext.traps[InvalidOperation] = 1
setcontext(DefaultContext)
```

```
# Afterwards, the threads can be started
t1.start()
t2.start()
t3.start()
. . .
```

## Recipes

Here are a few recipes that serve as utility functions and that demonstrate ways to work with the `Decimal` class:

```
def moneyfmt(value, places=2, curr='', sep=',', dp='.',
             pos='', neg='-', trailneg=''):
    """Convert Decimal to a money formatted string.

    places:  required number of places after the decimal
    curr:    optional currency symbol before the sign (m
    sep:     optional grouping separator (comma, period,
    dp:      decimal point indicator (comma or period)
             only specify as blank when places is zero
    pos:     optional sign for positive numbers: '+', sp
    neg:     optional sign for negative numbers: '-', '
    trailneg: optional trailing minus indicator:  '-', '

    >>> d = Decimal('-1234567.8901')
    >>> moneyfmt(d, curr='$')
    '-$1,234,567.89'
    >>> moneyfmt(d, places=0, sep='.', dp='', neg='', tr
    '1.234.568-'
    >>> moneyfmt(d, curr='$', neg='(', trailneg=')')
    '($1,234,567.89)'
    >>> moneyfmt(Decimal(123456789), sep=' ')
    '123 456 789.00'
    >>> moneyfmt(Decimal('-0.02'), neg='<', trailneg='>')
```

```
'<0.02>'
```

```
"""
```

```
q = Decimal(10) ** -places      # 2 places --> '0.01'
sign, digits, exp = value.quantize(q).as_tuple()
result = []
digits = list(map(str, digits))
build, next = result.append, digits.pop
if sign:
    build(trailneg)
for i in range(places):
    build(next() if digits else '0')
if places:
    build(dp)
if not digits:
    build('0')
i = 0
while digits:
    build(next())
    i += 1
    if i == 3 and digits:
        i = 0
        build(sep)
build(curr)
build(neg if sign else pos)
return ''.join(reversed(result))
```

```
def pi():
```

```
    """Compute Pi to the current precision.
```

```

## Decimal FAQ

**Q.** It is cumbersome to type `decimal.Decimal('1234.5')`. Is there a way to minimize typing when using the interactive interpreter?

**A.** Some users abbreviate the constructor to just a single letter:

```

>>> D = decimal.Decimal
>>> D('1.23') + D('3.45')
Decimal('4.68')

```

**Q.** In a fixed-point application with two decimal places, some inputs have many places and need to be rounded. Others are not supposed to have excess digits and need to be validated. What methods should be used?

**A.** The `quantize()` method rounds to a fixed number of decimal places. If the `Inexact` trap is set, it is also useful for validation:

```

>>> TWOPLACES = Decimal(10) ** -2           # same as Decimal('0.01')

>>> # Round to two places
>>> Decimal('3.214').quantize(TWOPLACES)
Decimal('3.21')

>>> # Validate that a number does not exceed two places
>>> Decimal('3.21').quantize(TWOPLACES, context=Context(
Decimal('3.21'))

>>> Decimal('3.214').quantize(TWOPLACES, context=Context(
Traceback (most recent call last):

```

...

Inexact: None

**Q.** Once I have valid two place inputs, how do I maintain that invariant throughout an application?

**A.** Some operations like addition, subtraction, and multiplication by an integer will automatically preserve fixed point. Others operations, like division and non-integer multiplication, will change the number of decimal places and need to be followed-up with a `quantize()` step:

```
>>> a = Decimal('102.72')           # Initial fixed-point
>>> b = Decimal('3.17')
>>> a + b                             # Addition preserves
Decimal('105.89')
>>> a - b
Decimal('99.55')
>>> a * 42                             # So does integer mu
Decimal('4314.24')
>>> (a * b).quantize(TWOPLACES)       # Must quantize non-
Decimal('325.62')
>>> (b / a).quantize(TWOPLACES)       # And quantize divis
Decimal('0.03')
```

In developing fixed-point applications, it is convenient to define functions to handle the `quantize()` step:

```
>>> def mul(x, y, fp=TWOPLACES):
...     return (x * y).quantize(fp)
>>> def div(x, y, fp=TWOPLACES):
...     return (x / y).quantize(fp)

>>> mul(a, b)                          # Automatically pres
Decimal('325.62')
>>> div(b, a)
Decimal('0.03')
```

**Q.** There are many ways to express the same value. The numbers 200, 200.000, 2E2, and .02E+4 all have the same value at

various precisions. Is there a way to transform them to a single recognizable canonical value?

A. The `normalize()` method maps all equivalent values to a single representative:

```
>>> values = map(Decimal, '200 200.000 2E2 .02E+4'.split)
>>> [v.normalize() for v in values]
[Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2'), Deci
```

Q. When does rounding occur in a computation?

A. It occurs *after* the computation. The philosophy of the decimal specification is that numbers are considered exact and are created independent of the current context. They can even have greater precision than current context. Computations process with those exact inputs and then rounding (or other context operations) is applied to the *result* of the computation:

```
>>> getcontext().prec = 5
>>> pi = Decimal('3.1415926535')    # More than 5 digits
>>> pi                               # All digits are retained
Decimal('3.1415926535')
>>> pi + 0                           # Rounded after an addition
Decimal('3.1416')
>>> pi - Decimal('0.00005')         # Subtract unrounded
Decimal('3.1415')
>>> pi + 0 - Decimal('0.00005').    # Intermediate values rounded
Decimal('3.1416')
```

Q. Some decimal values always print with exponential notation. Is there a way to get a non-exponential representation?

A. For some values, exponential notation is the only way to express the number of significant places in the coefficient. For example, expressing `5.0E+3` as `5000` keeps the value constant but cannot show the original's two-place significance.

If an application does not care about tracking significance, it is easy to remove the exponent and trailing zeroes, losing significance, but keeping the value unchanged:

```
>>> def remove_exponent(d):  
...     return d.quantize(Decimal(1)) if d == d.to_integ  
  
>>> remove_exponent(Decimal('5E+3'))  
Decimal('5000')
```

Q. Is there a way to convert a regular float to a **Decimal**?

A. Yes, any binary floating point number can be exactly expressed as a Decimal though an exact conversion may take more precision than intuition would suggest:

```
>>> Decimal(math.pi)  
Decimal('3.141592653589793115997963468544185161590576171')
```

Q. Within a complex calculation, how can I make sure that I haven't gotten a spurious result because of insufficient precision or rounding anomalies.

A. The decimal module makes it easy to test results. A best practice is to re-run calculations using greater precision and with various rounding modes. Widely differing results indicate insufficient precision, rounding mode issues, ill-conditioned inputs, or a numerically unstable algorithm.

Q. I noticed that context precision is applied to the results of operations but not to the inputs. Is there anything to watch out for when mixing values of different precisions?

A. Yes. The principle is that all values are considered to be exact and so is the arithmetic on those values. Only the results are rounded. The advantage for inputs is that “what you type is what you get”. A disadvantage is that the results can look odd if you forget that the inputs haven't been rounded:

```
>>> getcontext().prec = 3  
>>> Decimal('3.104') + Decimal('2.104')  
Decimal('5.21')  
>>> Decimal('3.104') + Decimal('0.000') + Decimal('2.104')  
Decimal('5.20')
```

The solution is either to increase precision or to force rounding of inputs using the unary plus operation:

```
>>> getcontext().prec = 3
>>> +Decimal('1.23456789')          # unary plus triggers ro
Decimal('1.23')
```

Alternatively, inputs can be rounded upon creation using the `Context.create_decimal()` method:

```
>>> Context(prec=5, rounding=ROUND_DOWN).create_decimal(
Decimal('1.2345'))
```

Q. Is the CPython implementation fast for large numbers?

A. Yes. In the CPython and PyPy3 implementations, the C/CFFI versions of the decimal module integrate the high speed [libmpdec](https://www.bytereef.org/mpdecimal/doc/libmpdec/index.html) [https://www.bytereef.org/mpdecimal/doc/libmpdec/index.html] library for arbitrary precision correctly rounded decimal floating point arithmetic 1. `libmpdec` uses [Karatsuba multiplication](https://en.wikipedia.org/wiki/Karatsuba_algorithm) [https://en.wikipedia.org/wiki/Karatsuba\_algorithm] for medium-sized numbers and the [Number Theoretic Transform](https://en.wikipedia.org/wiki/Discrete_Fourier_transform_(general)#Number-theoretic_transform) [https://en.wikipedia.org/wiki/Discrete\_Fourier\_transform\_(general)#Number-theoretic\_transform] for very large numbers.

The context must be adapted for exact arbitrary precision arithmetic. **Emin** and **Emax** should always be set to the maximum values, **clamp** should always be 0 (the default). Setting **prec** requires some care.

The easiest approach for trying out bignum arithmetic is to use the maximum value for **prec** as well 2:

```
>>> setcontext(Context(prec=MAX_PREC, Emax=MAX_EMAX, Emin=
>>> x = Decimal(2) ** 256
>>> x / 128
Decimal('90462569716653277674664832038037428010367175520
```

For inexact results, `MAX_PREC` is far too large on 64-bit platforms and the available memory will be insufficient:

```
>>> Decimal(1) / 3
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
MemoryError
```

On systems with overallocation (e.g. Linux), a more sophisticated approach is to adjust **prec** to the amount of available RAM. Suppose that you have 8GB of RAM and expect 10 simultaneous operands using a maximum of 500MB each:

```
>>> import sys
>>>
>>> # Maximum number of digits for a single operand using
>>> # with 19 digits per word (4-byte and 9 digits for tail)
>>> maxdigits = 19 * ((500 * 1024**2) // 8)
>>>
>>> # Check that this works:
>>> c = Context(prec=maxdigits, Emax=MAX_EMAX, Emin=MIN_EMIN)
>>> c.traps[Inexact] = True
>>> setcontext(c)
>>>
>>> # Fill the available precision with nines:
>>> x = Decimal(0).logical_invert() * 9
>>> sys.getsizeof(x)
524288112
>>> x + 2
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.Inexact: [<class 'decimal.Inexact'>]
```

In general (and especially on systems without overallocation), it is recommended to estimate even tighter bounds and set the **Inexact** trap if all calculations are expected to be exact.

1

*New in version 3.3.*

2

*Changed in version 3.9:* This approach now works for all exact

results except for non-integer powers.

# `fractions` — Rational numbers

**Source code:** [Lib/fractions.py](https://github.com/python/cpython/tree/3.11/Lib/fractions.py) [https://github.com/python/cpython/tree/3.11/Lib/fractions.py]

---

The `fractions` module provides support for rational number arithmetic.

A `Fraction` instance can be constructed from a pair of integers, from another rational number, or from a string.

```
class fractions.Fraction(numerator=0, denominator=1)
```

```
class fractions.Fraction(other_fraction)
```

```
class fractions.Fraction(float)
```

```
class fractions.Fraction(decimal)
```

```
class fractions.Fraction(string)
```

The first version requires that *numerator* and *denominator* are instances of `numbers.Rational` and returns a new `Fraction` instance with value `numerator/denominator`. If *denominator* is `0`, it raises a `ZeroDivisionError`. The second version requires that *other\_fraction* is an instance of `numbers.Rational` and returns a `Fraction` instance with the same value. The next two versions accept either a `float` or a `decimal.Decimal` instance, and return a `Fraction` instance with exactly the same value. Note that due to the usual issues with binary floating-point (see [Floating Point Arithmetic: Issues and Limitations](#)), the argument to `Fraction(1.1)` is not exactly equal to `11/10`, and so `Fraction(1.1)` does *not* return `Fraction(11, 10)` as one might expect. (But see the documentation for the `limit_denominator()` method below.) The last version of the constructor expects a string or unicode instance. The

usual form for this instance is:

```
[sign] numerator ['/ ' denominator]
```

where the optional `sign` may be either '+' or '-' and `numerator` and `denominator` (if present) are strings of decimal digits (underscores may be used to delimit digits as with integral literals in code). In addition, any string that represents a finite value and is accepted by the `float` constructor is also accepted by the `Fraction` constructor. In either form the input string may also have leading and/or trailing whitespace. Here are some examples:

```
>>> from fractions import Fraction
>>> Fraction(16, -10)
Fraction(-8, 5)
>>> Fraction(123)
Fraction(123, 1)
>>> Fraction()
Fraction(0, 1)
>>> Fraction('3/7')
Fraction(3, 7)
>>> Fraction(' -3/7 ')
Fraction(-3, 7)
>>> Fraction('1.414213 \t\n')
Fraction(1414213, 1000000)
>>> Fraction('-.125')
Fraction(-1, 8)
>>> Fraction('7e-6')
Fraction(7, 1000000)
>>> Fraction(2.25)
Fraction(9, 4)
>>> Fraction(1.1)
Fraction(2476979795053773, 2251799813685248)
>>> from decimal import Decimal
>>> Fraction(Decimal('1.1'))
Fraction(11, 10)
```

The `Fraction` class inherits from the abstract base class `numbers.Rational`, and implements all of the methods and

operations from that class. **Fraction** instances are **hashable**, and should be treated as immutable. In addition, **Fraction** has the following properties and methods:

*Changed in version 3.2:* The **Fraction** constructor now accepts **float** and **decimal.Decimal** instances.

*Changed in version 3.9:* The **math.gcd()** function is now used to normalize the *numerator* and *denominator*. **math.gcd()** always return a **int** type. Previously, the GCD type depended on *numerator* and *denominator*.

*Changed in version 3.11:* Underscores are now permitted when creating a **Fraction** instance from a string, following **PEP 515** [<https://peps.python.org/pep-0515/>] rules.

*Changed in version 3.11:* **Fraction** implements `__int__` now to satisfy `typing.SupportsInt` instance checks.

**numerator**

Numerator of the Fraction in lowest term.

**denominator**

Denominator of the Fraction in lowest term.

**as\_integer\_ratio()**

Return a tuple of two integers, whose ratio is equal to the Fraction and with a positive denominator.

*New in version 3.8.*

**classmethod from\_float(*flt*)**

Alternative constructor which only accepts instances of **float** or **numbers.Integral**. Beware that `Fraction.from_float(0.3)` is not the same value as `Fraction(3, 10)`.

**Note**

From Python 3.2 onwards, you can also construct a `Fraction` instance directly from a `float`.

*classmethod* `from_decimal(dec)`

Alternative constructor which only accepts instances of `decimal.Decimal` or `numbers.Integral`.

### Note

From Python 3.2 onwards, you can also construct a `Fraction` instance directly from a `decimal.Decimal` instance.

`limit_denominator(max_denominator=1000000)`

Finds and returns the closest `Fraction` to `self` that has denominator at most `max_denominator`. This method is useful for finding rational approximations to a given floating-point number:

```
>>> from fractions import Fraction
>>> Fraction('3.1415926535897932').limit_denominator()
Fraction(355, 113)
```

or for recovering a rational number that's represented as a float:

```
>>> from math import pi, cos
>>> Fraction(cos(pi/3))
Fraction(4503599627370497, 9007199254740992)
>>> Fraction(cos(pi/3)).limit_denominator()
Fraction(1, 2)
>>> Fraction(1.1).limit_denominator()
Fraction(11, 10)
```

`_floor_()`

Returns the greatest `int` `<= self`. This method can

also be accessed through the `math.floor()` function:

```
>>> from math import floor
>>> floor(Fraction(355, 113))
3
```

### `_ceil_()`

Returns the least `int` `>= self`. This method can also be accessed through the `math.ceil()` function.

### `_round_()`

#### `_round_(ndigits)`

The first version returns the nearest `int` to `self`, rounding half to even. The second version rounds `self` to the nearest multiple of `Fraction(1, 10**ndigits)` (logically, if `ndigits` is negative), again rounding half toward even. This method can also be accessed through the `round()` function.

The abstract base classes making up the numeric tower.

# random — Generate pseudo-random numbers

**Source code:** [Lib/random.py](https://github.com/python/cpython/tree/3.11/Lib/random.py) [https://github.com/python/cpython/tree/3.11/Lib/random.py]

---

This module implements pseudo-random number generators for various distributions.

For integers, there is uniform selection from a range. For sequences, there is uniform selection of a random element, a function to generate a random permutation of a list in-place, and a function for random sampling without replacement.

On the real line, there are functions to compute uniform, normal (Gaussian), lognormal, negative exponential, gamma, and beta distributions. For generating distributions of angles, the von Mises distribution is available.

Almost all module functions depend on the basic function `random()`, which generates a random float uniformly in the half-open range  $0.0 \leq x < 1.0$ . Python uses the Mersenne Twister as the core generator. It produces 53-bit precision floats and has a period of  $2^{19937}-1$ . The underlying implementation in C is both fast and threadsafe. The Mersenne Twister is one of the most extensively tested random number generators in existence. However, being completely deterministic, it is not suitable for all purposes, and is completely unsuitable for cryptographic purposes.

The functions supplied by this module are actually bound methods of a hidden instance of the `random.Random` class. You can instantiate your own instances of `Random` to get generators that don't share state.

Class `Random` can also be subclassed if you want to use a different

basic generator of your own devising: in that case, override the `random()`, `seed()`, `getstate()`, and `setstate()` methods. Optionally, a new generator can supply a `getrandbits()` method — this allows `randrange()` to produce selections over an arbitrarily large range.

The `random` module also provides the `SystemRandom` class which uses the system function `os.urandom()` to generate random numbers from sources provided by the operating system.

## Warning

The pseudo-random generators of this module should not be used for security purposes. For security or cryptographic uses, see the `secrets` module.

## See also

M. Matsumoto and T. Nishimura, “Mersenne Twister: A 623-dimensionally equidistributed uniform pseudorandom number generator”, ACM Transactions on Modeling and Computer Simulation Vol. 8, No. 1, January pp.3–30 1998.

[Complementary-Multiply-with-Carry recipe](https://code.activestate.com/recipes/576707/) [https://code.activestate.com/recipes/576707/] for a compatible alternative random number generator with a long period and comparatively simple update operations.

# Bookkeeping functions

`random.seed(a=None, version=2)`

Initialize the random number generator.

If `a` is omitted or `None`, the current system time is used. If randomness sources are provided by the operating system, they are used instead of the system time (see the `os.urandom()` function for details on availability).

If *a* is an int, it is used directly.

With version 2 (the default), a `str`, `bytes`, or `bytearray` object gets converted to an `int` and all of its bits are used.

With version 1 (provided for reproducing random sequences from older versions of Python), the algorithm for `str` and `bytes` generates a narrower range of seeds.

*Changed in version 3.2:* Moved to the version 2 scheme which uses all of the bits in a string seed.

*Changed in version 3.11:* The *seed* must be one of the following types: `NoneType`, `int`, `float`, `str`, `bytes`, or `bytearray`.

`random.getstate()`

Return an object capturing the current internal state of the generator. This object can be passed to `setstate()` to restore the state.

`random.setstate(state)`

*state* should have been obtained from a previous call to `getstate()`, and `setstate()` restores the internal state of the generator to what it was at the time `getstate()` was called.

## Functions for bytes

`random.randbytes(n)`

Generate *n* random bytes.

This method should not be used for generating security tokens. Use `secrets.token_bytes()` instead.

*New in version 3.9.*

## Functions for integers

`random.randrange(stop)`

`random.randrange(start, stop[, step])`

Return a randomly selected element from `range(start, stop, step)`. This is equivalent to `choice(range(start, stop, step))`, but doesn't actually build a range object.

The positional argument pattern matches that of `range()`. Keyword arguments should not be used because the function may use them in unexpected ways.

*Changed in version 3.2:* `randrange()` is more sophisticated about producing equally distributed values. Formerly it used a style like `int(random()*n)` which could produce slightly uneven distributions.

*Deprecated since version 3.10:* The automatic conversion of non-integer types to equivalent integers is deprecated. Currently `randrange(10.0)` is losslessly converted to `randrange(10)`. In the future, this will raise a `TypeError`.

*Deprecated since version 3.10:* The exception raised for non-integral values such as `randrange(10.5)` or `randrange('10')` will be changed from `ValueError` to `TypeError`.

`random.randint(a, b)`

Return a random integer  $N$  such that  $a \leq N \leq b$ . Alias for `randrange(a, b+1)`.

`random.getrandbits(k)`

Returns a non-negative Python integer with  $k$  random bits. This method is supplied with the MersenneTwister generator and some other generators may also provide it as an optional part of the API. When available, `getrandbits()` enables `randrange()` to handle arbitrarily large ranges.

*Changed in version 3.9:* This method now accepts zero for  $k$ .

# Functions for sequences

`random.choice(seq)`

Return a random element from the non-empty sequence *seq*. If *seq* is empty, raises `IndexError`.

`random.choices(population, weights=None, *, cum_weights=None, k=1)`

Return a *k* sized list of elements chosen from the *population* with replacement. If the *population* is empty, raises `IndexError`.

If a *weights* sequence is specified, selections are made according to the relative weights. Alternatively, if a *cum\_weights* sequence is given, the selections are made according to the cumulative weights (perhaps computed using `itertools.accumulate()`). For example, the relative weights `[10, 5, 30, 5]` are equivalent to the cumulative weights `[10, 15, 45, 50]`. Internally, the relative weights are converted to cumulative weights before making selections, so supplying the cumulative weights saves work.

If neither *weights* nor *cum\_weights* are specified, selections are made with equal probability. If a *weights* sequence is supplied, it must be the same length as the *population* sequence. It is a `TypeError` to specify both *weights* and *cum\_weights*.

The *weights* or *cum\_weights* can use any numeric type that interoperates with the `float` values returned by `random()` (that includes integers, floats, and fractions but excludes decimals). Weights are assumed to be non-negative and finite. A `ValueError` is raised if all weights are zero.

For a given seed, the `choices()` function with equal weighting typically produces a different sequence than repeated calls to `choice()`. The algorithm used by `choices()` uses floating point arithmetic for internal consistency and speed. The algorithm used by `choice()`

defaults to integer arithmetic with repeated selections to avoid small biases from round-off error.

*New in version 3.6.*

*Changed in version 3.9:* Raises a `ValueError` if all weights are zero.

`random.shuffle(x)`

Shuffle the sequence `x` in place.

To shuffle an immutable sequence and return a new shuffled list, use `sample(x, k=len(x))` instead.

Note that even for small `len(x)`, the total number of permutations of `x` can quickly grow larger than the period of most random number generators. This implies that most permutations of a long sequence can never be generated. For example, a sequence of length 2080 is the largest that can fit within the period of the Mersenne Twister random number generator.

*Deprecated since version 3.9, removed in version 3.11:* The optional parameter *random*.

`random.sample(population, k, *, counts=None)`

Return a `k` length list of unique elements chosen from the population sequence. Used for random sampling without replacement.

Returns a new list containing elements from the population while leaving the original population unchanged. The resulting list is in selection order so that all sub-slices will also be valid random samples. This allows raffle winners (the sample) to be partitioned into grand prize and second place winners (the subslices).

Members of the population need not be `hashable` or unique. If the population contains repeats, then each occurrence is a possible selection in the sample.

Repeated elements can be specified one at a time or with the optional keyword-only *counts* parameter. For example, `sample(['red', 'blue'], counts=[4, 2], k=5)` is equivalent to `sample(['red', 'red', 'red', 'red', 'blue', 'blue'], k=5)`.

To choose a sample from a range of integers, use a `range()` object as an argument. This is especially fast and space efficient for sampling from a large population:  
`sample(range(10000000), k=60)`.

If the sample size is larger than the population size, a `ValueError` is raised.

*Changed in version 3.9:* Added the *counts* parameter.

*Changed in version 3.11:* The *population* must be a sequence. Automatic conversion of sets to lists is no longer supported.

## Real-valued distributions

The following functions generate specific real-valued distributions. Function parameters are named after the corresponding variables in the distribution's equation, as used in common mathematical practice; most of these equations can be found in any statistics text.

`random.random()`

Return the next random floating point number in the range  
 $0.0 \leq X < 1.0$

`random.uniform(a, b)`

Return a random floating point number  $N$  such that  $a \leq N \leq b$  for  $a \leq b$  and  $b \leq N \leq a$  for  $b < a$ .

The end-point value  $b$  may or may not be included in the range depending on floating-point rounding in the equation  
 $a + (b-a) * \text{random}()$ .

`random.triangular(low, high, mode)`

Return a random floating point number  $N$  such that  $low \leq N \leq high$  and with the specified *mode* between those bounds. The *low* and *high* bounds default to zero and one. The *mode* argument defaults to the midpoint between the bounds, giving a symmetric distribution.

`random.betavariate(alpha, beta)`

Beta distribution. Conditions on the parameters are  $alpha > 0$  and  $beta > 0$ . Returned values range between 0 and 1.

`random.expovariate(lambd)`

Exponential distribution. *lambd* is 1.0 divided by the desired mean. It should be nonzero. (The parameter would be called “lambda”, but that is a reserved word in Python.) Returned values range from 0 to positive infinity if *lambd* is positive, and from negative infinity to 0 if *lambd* is negative.

`random.gammavariate(alpha, beta)`

Gamma distribution. (*Not* the gamma function!) The shape and scale parameters, *alpha* and *beta*, must have positive values. (Calling conventions vary and some sources define ‘beta’ as the inverse of the scale).

The probability distribution function is:

$$\text{pdf}(x) = \frac{x^{(\alpha - 1)} * \text{math.exp}(-x / \text{beta})}{\text{math.gamma}(\alpha) * \text{beta} ** \alpha}$$

`random.gauss(mu=0.0, sigma=1.0)`

Normal distribution, also called the Gaussian distribution. *mu* is the mean, and *sigma* is the standard deviation. This is slightly faster than the `normalvariate()` function defined below.

Multithreading note: When two threads call this function simultaneously, it is possible that they will receive the same return value. This can be avoided in three ways. 1) Have each

thread use a different instance of the random number generator. 2) Put locks around all calls. 3) Use the slower, but thread-safe `normalvariate()` function instead.

*Changed in version 3.11:  $\mu$  and  $\sigma$  now have default arguments.*

`random.lognormvariate( $\mu$ ,  $\sigma$ )`

Log normal distribution. If you take the natural logarithm of this distribution, you'll get a normal distribution with mean  $\mu$  and standard deviation  $\sigma$ .  $\mu$  can have any value, and  $\sigma$  must be greater than zero.

`random.normalvariate( $\mu=0.0$ ,  $\sigma=1.0$ )`

Normal distribution.  $\mu$  is the mean, and  $\sigma$  is the standard deviation.

*Changed in version 3.11:  $\mu$  and  $\sigma$  now have default arguments.*

`random.vonmisesvariate( $\mu$ ,  $\kappa$ )`

$\mu$  is the mean angle, expressed in radians between 0 and  $2\pi$ , and  $\kappa$  is the concentration parameter, which must be greater than or equal to zero. If  $\kappa$  is equal to zero, this distribution reduces to a uniform random angle over the range 0 to  $2\pi$ .

`random.paretovariate( $\alpha$ )`

Pareto distribution.  $\alpha$  is the shape parameter.

`random.weibullvariate( $\alpha$ ,  $\beta$ )`

Weibull distribution.  $\alpha$  is the scale parameter and  $\beta$  is the shape parameter.

## Alternative Generator

`class random.Random([seed])`

Class that implements the default pseudo-random number generator used by the `random` module.

*Deprecated since version 3.9:* In the future, the *seed* must be one of the following types: `NoneType`, `int`, `float`, `str`, `bytes`, or `bytearray`.

`class random.SystemRandom([seed])`

Class that uses the `os.urandom()` function for generating random numbers from sources provided by the operating system. Not available on all systems. Does not rely on software state, and sequences are not reproducible.

Accordingly, the `seed()` method has no effect and is ignored. The `getstate()` and `setstate()` methods raise `NotImplementedError` if called.

## Notes on Reproducibility

Sometimes it is useful to be able to reproduce the sequences given by a pseudo-random number generator. By re-using a seed value, the same sequence should be reproducible from run to run as long as multiple threads are not running.

Most of the random module's algorithms and seeding functions are subject to change across Python versions, but two aspects are guaranteed not to change:

- If a new seeding method is added, then a backward compatible seeder will be offered.
- The generator's `random()` method will continue to produce the same sequence when the compatible seeder is given the same seed.

## Examples

Basic examples:

```

>>> random()                                # Random float:
0.374444887175646646

>>> uniform(2.5, 10.0)                      # Random float:
3.1800146073117523

>>> expovariate(1 / 5)                      # Interval betw
5.148957571865031

>>> randrange(10)                           # Integer from
7

>>> randrange(0, 101, 2)                    # Even integer
26

>>> choice(['win', 'lose', 'draw'])          # Single random
'draw'

>>> deck = 'ace two three four'.split()
>>> shuffle(deck)                           # Shuffle a lis
>>> deck
['four', 'two', 'ace', 'three']

>>> sample([10, 20, 30, 40, 50], k=4)        # Four samples
[40, 10, 50, 30]

```

## Simulations:

```

>>> # Six roulette wheel spins (weighted sampling with r
>>> choices(['red', 'black', 'green'], [18, 18, 2], k=6)
['red', 'green', 'black', 'black', 'red', 'black']

>>> # Deal 20 cards without replacement from a deck
>>> # of 52 playing cards, and determine the proportion
>>> # with a ten-value: ten, jack, queen, or king.
>>> dealt = sample(['tens', 'low cards'], counts=[16, 36
>>> dealt.count('tens') / 20
0.15

```

```
>>> # Estimate the probability of getting 5 or more heads
>>> # of a biased coin that settles on heads 60% of the time
>>> def trial():
...     return choices('HT', cum_weights=(0.60, 1.00), k=5)
...
>>> sum(trial() for i in range(10_000)) / 10_000
0.4169

>>> # Probability of the median of 5 samples being in the middle
>>> def trial():
...     return 2_500 <= sorted(choices(range(10_000), k=5))
...
>>> sum(trial() for i in range(10_000)) / 10_000
0.7958
```

Example of [statistical bootstrapping](https://en.wikipedia.org/wiki/Bootstrapping_(statistics)) [https://en.wikipedia.org/wiki/Bootstrapping\_(statistics)] using resampling with replacement to estimate a confidence interval for the mean of a sample:

```
# https://www.thoughtco.com/example-of-bootstrapping-312
from statistics import fmean as mean
from random import choices

data = [41, 50, 29, 37, 81, 30, 73, 63, 20, 35, 68, 22, 19, 45, 67, 56, 32, 78, 65, 48]
means = sorted(mean(choices(data, k=len(data))) for i in range(100))
print(f'The sample mean of {mean(data):.1f} has a 90% confidence interval from {means[5]:.1f} to {means[94]:.1f}')
```

Example of a [resampling permutation test](https://en.wikipedia.org/wiki/Resampling_(statistics)#Permutation_tests) [https://en.wikipedia.org/wiki/Resampling\_(statistics)#Permutation\_tests] to determine the statistical significance or [p-value](https://en.wikipedia.org/wiki/P-value) [https://en.wikipedia.org/wiki/P-value] of an observed difference between the effects of a drug versus a placebo:

```
# Example from "Statistics is Easy" by Dennis Shasha and
from statistics import fmean as mean
from random import shuffle

drug = [54, 73, 53, 70, 73, 68, 52, 65, 65]
placebo = [54, 51, 58, 44, 55, 52, 42, 47, 58, 46]
```

```

observed_diff = mean(drug) - mean(placebo)

n = 10_000
count = 0
combined = drug + placebo
for i in range(n):
    shuffle(combined)
    new_diff = mean(combined[:len(drug)]) - mean(combined[len(drug):])
    count += (new_diff >= observed_diff)

print(f'{n} label reshufflings produced only {count} instances
print(f'at least as extreme as the observed difference')
print(f'The one-sided p-value of {count / n:.4f} leads us to reject the
print(f'hypothesis that there is no difference between treatment and control')

```

### Simulation of arrival times and service deliveries for a multiserver queue:

```

from heapq import heapify, heapreplace
from random import expovariate, gauss
from statistics import mean, quantiles

average_arrival_interval = 5.6
average_service_time = 15.0
stdev_service_time = 3.5
num_servers = 3

waits = []
arrival_time = 0.0
servers = [0.0] * num_servers # time when each server becomes available
heapify(servers)
for i in range(1_000_000):
    arrival_time += expovariate(1.0 / average_arrival_interval)
    next_server_available = servers[0]
    wait = max(0.0, next_server_available - arrival_time)
    waits.append(wait)
    service_duration = max(0.0, gauss(average_service_time, stdev_service_time))
    service_completed = arrival_time + wait + service_duration
    heapreplace(servers, service_completed)

```

```
print(f'Mean wait: {mean(waits):.1f}    Max wait: {max(waits):.1f}')
print('Quartiles:', [round(q, 1) for q in quantiles(waits)])
```

## Recipes

These recipes show how to efficiently make random selections from the combinatoric iterators in the [itertools](#) module:

```
def random_product(*args, repeat=1):
    "Random selection from itertools.product(*args, **kwargs)"
    pools = [tuple(pool) for pool in args] * repeat
    return tuple(map(random.choice, pools))

def random_permutation(iterable, r=None):
    "Random selection from itertools.permutations(iterable, r)"
    pool = tuple(iterable)
    r = len(pool) if r is None else r
    return tuple(random.sample(pool, r))
```

```
def random_combination(iterable, r):
    "Random selection from itertools.combinations(iterable, r)"
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.sample(range(n), r))
    return tuple(pool[i] for i in indices)

def random_combination_with_replacement(iterable, r):
    "Choose r elements with replacement. Order the results."
    # Result will be in set(itertools.combinations_with_replacement(iterable, r))
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.choices(range(n), k=r))
    return tuple(pool[i] for i in indices)
```

The default `random()` returns multiples of  $2^{-53}$  in the range  $0.0 \leq x < 1.0$ . All such numbers are evenly spaced and are exactly representable as Python floats. However, many other representable floats in that interval are not possible selections. For example, 0.05954861408025609 isn't an integer multiple of  $2^{-53}$ .

The following recipe takes a different approach. All floats in the interval are possible selections. The mantissa comes from a uniform distribution of integers in the range  $2^{52} \leq \text{mantissa} < 2^{53}$ . The exponent comes from a geometric distribution where exponents smaller than -53 occur half as often as the next larger exponent.

```
from random import Random
from math import ldexp

class FullRandom(Random):

    def random(self):
        mantissa = 0x10_0000_0000_0000 | self.getrandbits(52)
        exponent = -53
        x = 0
        while not x:
            x = self.getrandbits(32)
```

```
        exponent += x.bit_length() - 32
    return ldexp(mantissa, exponent)
```

All [real valued distributions](#) in the class will use the new method:

```
>>> fr = FullRandom()
>>> fr.random()
0.05954861408025609
>>> fr.expovariate(0.25)
8.87925541791544
```

The recipe is conceptually equivalent to an algorithm that chooses from all the multiples of  $2^{-1074}$  in the range  $0.0 \leq x < 1.0$ . All such numbers are evenly spaced, but most have to be rounded down to the nearest representable Python float. (The value  $2^{-1074}$  is the smallest positive unnormalized float and is equal to `math.ulp(0.0)`.)

# statistics — Mathematical statistics functions

*New in version 3.4.*

**Source code:** [Lib/statistics.py](https://github.com/python/cpython/tree/3.11/Lib/statistics.py) [https://github.com/python/cpython/tree/3.11/Lib/statistics.py]

---

This module provides functions for calculating mathematical statistics of numeric (**Real**-valued) data.

The module is not intended to be a competitor to third-party libraries such as **NumPy** [https://numpy.org], **SciPy** [https://scipy.org/], or proprietary full-featured statistics packages aimed at professional statisticians such as Minitab, SAS and Matlab. It is aimed at the level of graphing and scientific calculators.

Unless explicitly noted, these functions support **int**, **float**, **Decimal** and **Fraction**. Behaviour with other types (whether in the numeric tower or not) is currently unsupported. Collections with a mix of types are also undefined and implementation-dependent. If your input data consists of mixed types, you may be able to use **map()** to ensure a consistent result, for example:

```
map(float, input_data).
```

Some datasets use NaN (not a number) values to represent missing data. Since NaNs have unusual comparison semantics, they cause surprising or undefined behaviors in the statistics functions that sort data or that count occurrences. The functions affected are `median()`, `median_low()`, `median_high()`, `median_grouped()`, `mode()`, `multimode()`, and `quantiles()`. The NaN values should be stripped before calling these functions:

```
>>> from statistics import median
```

```
>>> from math import isnan
>>> from itertools import filterfalse

>>> data = [20.7, float('NaN'), 19.2, 18.3, float('NaN'),
>>> sorted(data) # This has surprising behavior
[20.7, nan, 14.4, 18.3, 19.2, nan]
>>> median(data) # This result is unexpected
16.35

>>> sum(map(isnan, data)) # Number of missing values
2
>>> clean = list(filterfalse(isnan, data)) # Strip NaN
>>> clean
[20.7, 19.2, 18.3, 14.4]
>>> sorted(clean) # Sorting now works as expected
[14.4, 18.3, 19.2, 20.7]
>>> median(clean) # This result is now well defined
18.75
```

## Averages and measures of central location

These functions calculate an average or typical value from a population or sample.

[Arithmetic mean](#) (“average”) of data.

[Fast\\_float](#) floating point arithmetic mean, with optional weighting.

[Geometric mean](#) of data.

[Harmonic mean](#) of data.

[Median](#) (middle value) of data.

[Low median](#) of data.

[High median](#) of data.

[Median\\_or\\_50th\\_percentile](#), of grouped data.

[Single](#) (mode (most common value) of discrete or nominal data.

[List of modes](#) (most common values) of discrete or nominal data.

[Divide data into](#) intervals with equal probability.

## Measures of spread

These functions calculate a measure of how much the population or sample tends to deviate from the typical or average values.

`Population` standard deviation of data.

---

`Population` variance of data.

---

`Sample` standard deviation of data.

---

`Sample` variance of data.

---

## Statistics for relations between two inputs

These functions calculate statistics regarding relations between two inputs.

`Sample` covariance for two variables.

---

`Pearson's` correlation coefficient for two variables.

---

`Slope and intercept` for simple linear regression.

---

## Function details

Note: The functions do not require the data given to them to be sorted. However, for reading convenience, most of the examples show sorted sequences.

`statistics.mean(data)`

Return the sample arithmetic mean of *data* which can be a sequence or iterable.

The arithmetic mean is the sum of the data divided by the number of data points. It is commonly called “the average”, although it is only one of many different mathematical averages. It is a measure of the central location of the data.

If *data* is empty, `StatisticsError` will be raised.

Some examples of use:

```
>>> mean([1, 2, 3, 4, 4])
```

```
2.8
```

```
>>> mean([-1.0, 2.5, 3.25, 5.75])
```

2.625

```
>>> from fractions import Fraction as F
>>> mean([F(3, 7), F(1, 21), F(5, 3), F(1, 3)])
Fraction(13, 21)

>>> from decimal import Decimal as D
>>> mean([D("0.5"), D("0.75"), D("0.625"), D("0.375")])
Decimal('0.5625')
```

## Note

The mean is strongly affected by [outliers](https://en.wikipedia.org/wiki/Outlier) [https://en.wikipedia.org/wiki/Outlier] and is not necessarily a typical example of the data points. For a more robust, although less efficient, measure of [central tendency](https://en.wikipedia.org/wiki/Central_tendency) [https://en.wikipedia.org/wiki/Central\_tendency], see [median\(\)](#).

The sample mean gives an unbiased estimate of the true population mean, so that when taken on average over all the possible samples, `mean(sample)` converges on the true mean of the entire population. If *data* represents the entire population rather than a sample, then `mean(data)` is equivalent to calculating the true population mean  $\mu$ .

`statistics.fmean(data, weights=None)`

Convert *data* to floats and compute the arithmetic mean.

This runs faster than the [mean\(\)](#) function and it always returns a [float](#). The *data* may be a sequence or iterable. If the input dataset is empty, raises a [StatisticsError](#).

```
>>> fmean([3.5, 4.0, 5.25])
4.25
```

Optional weighting is supported. For example, a professor assigns a grade for a course by weighting quizzes at 20%, homework at 20%, a midterm exam at 30%, and a final exam

at 30%:

```
>>> grades = [85, 92, 83, 91]
>>> weights = [0.20, 0.20, 0.30, 0.30]
>>> fmean(grades, weights)
87.6
```

If *weights* is supplied, it must be the same length as the *data* or a **ValueError** will be raised.

*New in version 3.8.*

*Changed in version 3.11:* Added support for *weights*.

`statistics.geometric_mean(data)`

Convert *data* to floats and compute the geometric mean.

The geometric mean indicates the central tendency or typical value of the *data* using the product of the values (as opposed to the arithmetic mean which uses their sum).

Raises a **StatisticsError** if the input dataset is empty, if it contains a zero, or if it contains a negative value. The *data* may be a sequence or iterable.

No special efforts are made to achieve exact results.  
(However, this may change in the future.)

```
>>> round(geometric_mean([54, 24, 36]), 1)
36.0
```

*New in version 3.8.*

`statistics.harmonic_mean(data, weights=None)`

Return the harmonic mean of *data*, a sequence or iterable of real-valued numbers. If *weights* is omitted or *None*, then equal weighting is assumed.

The harmonic mean is the reciprocal of the arithmetic **mean()** of the reciprocals of the data. For example, the

harmonic mean of three values  $a$ ,  $b$  and  $c$  will be equivalent to  $3 / (1/a + 1/b + 1/c)$ . If one of the values is zero, the result will be zero.

The harmonic mean is a type of average, a measure of the central location of the data. It is often appropriate when averaging ratios or rates, for example speeds.

Suppose a car travels 10 km at 40 km/hr, then another 10 km at 60 km/hr. What is the average speed?

```
>>> harmonic_mean([40, 60])  
48.0
```

Suppose a car travels 40 km/hr for 5 km, and when traffic clears, speeds-up to 60 km/hr for the remaining 30 km of the journey. What is the average speed?

```
>>> harmonic_mean([40, 60], weights=[5, 30])  
56.0
```

**StatisticsError** is raised if *data* is empty, any element is less than zero, or if the weighted sum isn't positive.

The current algorithm has an early-out when it encounters a zero in the input. This means that the subsequent inputs are not tested for validity. (This behavior may change in the future.)

*New in version 3.6.*

*Changed in version 3.10:* Added support for *weights*.

`statistics.median(data)`

Return the median (middle value) of numeric data, using the common “mean of middle two” method. If *data* is empty, **StatisticsError** is raised. *data* can be a sequence or iterable.

The median is a robust measure of central location and is less affected by the presence of outliers. When the number of data

points is odd, the middle data point is returned:

```
>>> median([1, 3, 5])  
3
```

When the number of data points is even, the median is interpolated by taking the average of the two middle values:

```
>>> median([1, 3, 5, 7])  
4.0
```

This is suited for when your data is discrete, and you don't mind that the median may not be an actual data point.

If the data is ordinal (supports order operations) but not numeric (doesn't support addition), consider using `median_low()` or `median_high()` instead.

`statistics.median_low(data)`

Return the low median of numeric data. If *data* is empty, `StatisticsError` is raised. *data* can be a sequence or iterable.

The low median is always a member of the data set. When the number of data points is odd, the middle value is returned. When it is even, the smaller of the two middle values is returned.

```
>>> median_low([1, 3, 5])  
3  
>>> median_low([1, 3, 5, 7])  
3
```

Use the low median when your data are discrete and you prefer the median to be an actual data point rather than interpolated.

`statistics.median_high(data)`

Return the high median of data. If *data* is empty, `StatisticsError` is raised. *data* can be a sequence or

iterable.

The high median is always a member of the data set. When the number of data points is odd, the middle value is returned. When it is even, the larger of the two middle values is returned.

```
>>> median_high([1, 3, 5])
3
>>> median_high([1, 3, 5, 7])
5
```

Use the high median when your data are discrete and you prefer the median to be an actual data point rather than interpolated.

`statistics.median_grouped(data, interval=1)`

Return the median of grouped continuous data, calculated as the 50th percentile, using interpolation. If *data* is empty, **StatisticsError** is raised. *data* can be a sequence or iterable.

```
>>> median_grouped([52, 52, 53, 54])
52.5
```

In the following example, the data are rounded, so that each value represents the midpoint of data classes, e.g. 1 is the midpoint of the class 0.5–1.5, 2 is the midpoint of 1.5–2.5, 3 is the midpoint of 2.5–3.5, etc. With the data given, the middle value falls somewhere in the class 3.5–4.5, and interpolation is used to estimate it:

```
>>> median_grouped([1, 2, 2, 3, 4, 4, 4, 4, 4, 5])
3.7
```

Optional argument *interval* represents the class interval, and defaults to 1. Changing the class interval naturally will change the interpolation:

```
>>> median_grouped([1, 3, 3, 5, 7], interval=1)
```

3.25

```
>>> median_grouped([1, 3, 3, 5, 7], interval=2)
3.5
```

This function does not check whether the data points are at least *interval* apart.

**CPython implementation detail:** Under some circumstances, `median_grouped()` may coerce data points to floats. This behaviour is likely to change in the future.

`statistics.mode(data)`

Return the single most common data point from discrete or nominal *data*. The mode (when it exists) is the most typical value and serves as a measure of central location.

If there are multiple modes with the same frequency, returns the first one encountered in the *data*. If the smallest or largest of those is desired instead, use `min(multimode(data))` or `max(multimode(data))`. If the input *data* is empty, `StatisticsError` is raised.

`mode` assumes discrete data and returns a single value. This is the standard treatment of the mode as commonly taught in schools:

```
>>> mode([1, 1, 2, 3, 3, 3, 3, 4])
3
```

The mode is unique in that it is the only statistic in this package that also applies to nominal (non-numeric) data:

```
>>> mode(["red", "blue", "blue", "red", "green", "red", "red"])
```

*Changed in version 3.8:* Now handles multimodal datasets by returning the first mode encountered. Formerly, it raised **StatisticsError** when more than one mode was found.

`statistics.multimode(data)`

Return a list of the most frequently occurring values in the order they were first encountered in the *data*. Will return more than one result if there are multiple modes or an empty list if the *data* is empty:

```
>>> multimode('aabbbbccdddeeffffgg')
['b', 'd', 'f']
>>> multimode('')
[]
```

*New in version 3.8.*

`statistics.pstdev(data, mu=None)`

Return the population standard deviation (the square root of the population variance). See **pvariance()** for arguments and other details.

```
>>> pstdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
0.986893273527251
```

`statistics.pvariance(data, mu=None)`

Return the population variance of *data*, a non-empty sequence or iterable of real-valued numbers. Variance, or second moment about the mean, is a measure of the variability (spread or dispersion) of data. A large variance indicates that the data is spread out; a small variance indicates it is clustered closely around the mean.

If the optional second argument *mu* is given, it is typically the mean of the *data*. It can also be used to compute the second moment around a point that is not the mean. If it is missing or `None` (the default), the arithmetic mean is automatically calculated.

Use this function to calculate the variance from the entire population. To estimate the variance from a sample, the `variance()` function is usually a better choice.

Raises `StatisticsError` if *data* is empty.

Examples:

```
>>> data = [0.0, 0.25, 0.25, 1.25, 1.5, 1.75, 2.75,
>>> pvariance(data)
1.25
```

If you have already calculated the mean of your data, you can pass it as the optional second argument *mu* to avoid recalculation:

```
>>> mu = mean(data)
>>> pvariance(data, mu)
1.25
```

Decimals and Fractions are supported:

```
>>> from decimal import Decimal as D
>>> pvariance([D("27.5"), D("30.25"), D("30.25"), D("24.815")])

>>> from fractions import Fraction as F
>>> pvariance([F(1, 4), F(5, 4), F(1, 2)])
Fraction(13, 72)
```

### Note

When called with the entire population, this gives the population variance  $\sigma^2$ . When called on a sample instead, this is the biased sample variance  $s^2$ , also known as

variance with  $N$  degrees of freedom.

If you somehow know the true population mean  $\mu$ , you may use this function to calculate the variance of a sample, giving the known population mean as the second argument. Provided the data points are a random sample of the population, the result will be an unbiased estimate of the population variance.

`statistics.stdev(data, xbar=None)`

Return the sample standard deviation (the square root of the sample variance). See `variance()` for arguments and other details.

```
>>> stdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
1.0810874155219827
```

`statistics.variance(data, xbar=None)`

Return the sample variance of *data*, an iterable of at least two real-valued numbers. Variance, or second moment about the mean, is a measure of the variability (spread or dispersion) of data. A large variance indicates that the data is spread out; a small variance indicates it is clustered closely around the mean.

If the optional second argument *xbar* is given, it should be the mean of *data*. If it is missing or `None` (the default), the mean is automatically calculated.

Use this function when your data is a sample from a population. To calculate the variance from the entire population, see `pvariance()`.

Raises `StatisticsError` if *data* has fewer than two values.

Examples:

```
>>> data = [2.75, 1.75, 1.25, 0.25, 0.5, 1.25, 3.5]
```

```
>>> variance(data)
1.3720238095238095
```

If you have already calculated the mean of your data, you can pass it as the optional second argument *xbar* to avoid recalculation:

```
>>> m = mean(data)
>>> variance(data, m)
1.3720238095238095
```

This function does not attempt to verify that you have passed the actual mean as *xbar*. Using arbitrary values for *xbar* can lead to invalid or impossible results.

Decimal and Fraction values are supported:

```
>>> from decimal import Decimal as D
>>> variance([D("27.5"), D("30.25"), D("30.25"), D(
Decimal('31.01875'))

>>> from fractions import Fraction as F
>>> variance([F(1, 6), F(1, 2), F(5, 3)])
Fraction(67, 108)
```

## Note

This is the sample variance  $s^2$  with Bessel's correction, also known as variance with  $N-1$  degrees of freedom. Provided that the data points are representative (e.g. independent and identically distributed), the result should be an unbiased estimate of the true population variance.

If you somehow know the actual population mean  $\mu$  you should pass it to the **pvariance()** function as the *mu* parameter to get the variance of a sample.

`statistics.quantiles(data, *, n=4, method='exclusive')`

Divide *data* into *n* continuous intervals with equal

probability. Returns a list of  $n - 1$  cut points separating the intervals.

Set  $n$  to 4 for quartiles (the default). Set  $n$  to 10 for deciles. Set  $n$  to 100 for percentiles which gives the 99 cuts points that separate *data* into 100 equal sized groups. Raises **StatisticsError** if  $n$  is not least 1.

The *data* can be any iterable containing sample data. For meaningful results, the number of data points in *data* should be larger than  $n$ . Raises **StatisticsError** if there are not at least two data points.

The cut points are linearly interpolated from the two nearest data points. For example, if a cut point falls one-third of the distance between two sample values, 100 and 112, the cut-point will evaluate to 104.

The *method* for computing quantiles can be varied depending on whether the *data* includes or excludes the lowest and highest possible values from the population.

The default *method* is “exclusive” and is used for data sampled from a population that can have more extreme values than found in the samples. The portion of the population falling below the  $i$ -th of  $m$  sorted data points is computed as  $i / (m + 1)$ . Given nine sample values, the method sorts them and assigns the following percentiles: 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%.

Setting the *method* to “inclusive” is used for describing population data or for samples that are known to include the most extreme values from the population. The minimum value in *data* is treated as the 0th percentile and the maximum value is treated as the 100th percentile. The portion of the population falling below the  $i$ -th of  $m$  sorted data points is computed as  $(i - 1) / (m - 1)$ . Given 11 sample values, the method sorts them and assigns the following percentiles: 0%, 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 100%.

```
# Decile cut points for empirically sampled data
>>> data = [105, 129, 87, 86, 111, 111, 89, 81, 108
...         100, 75, 105, 103, 109, 76, 119, 99, 91
...         106, 101, 84, 111, 74, 87, 86, 103, 103
...         111, 75, 87, 102, 121, 111, 88, 89, 101
...         103, 107, 101, 81, 109, 104]
>>> [round(q, 1) for q in quantiles(data, n=10)]
[81.0, 86.2, 89.0, 99.4, 102.5, 103.6, 106.0, 109.8
```

*New in version 3.8.*

`statistics.covariance(x, y, /)`

Return the sample covariance of two inputs *x* and *y*.  
Covariance is a measure of the joint variability of two inputs.

Both inputs must be of the same length (no less than two),  
otherwise **StatisticsError** is raised.

Examples:

```
>>> x = [1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> y = [1, 2, 3, 1, 2, 3, 1, 2, 3]
>>> covariance(x, y)
0.75
>>> z = [9, 8, 7, 6, 5, 4, 3, 2, 1]
>>> covariance(x, z)
-7.5
>>> covariance(z, x)
-7.5
```

*New in version 3.10.*

`statistics.correlation(x, y, /)`

Return the **Pearson's correlation coefficient** [[https://en.wikipedia.org/wiki/Pearson\\_correlation\\_coefficient](https://en.wikipedia.org/wiki/Pearson_correlation_coefficient)] for two inputs.  
Pearson's correlation coefficient *r* takes values between -1 and +1. It measures the strength and direction of the linear relationship, where +1 means very strong, positive linear relationship, -1 very strong, negative linear relationship, and

0 no linear relationship.

Both inputs must be of the same length (no less than two), and need not to be constant, otherwise `StatisticsError` is raised.

Examples:

```
>>> x = [1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> y = [9, 8, 7, 6, 5, 4, 3, 2, 1]
>>> correlation(x, x)
1.0
>>> correlation(x, y)
-1.0
```

*New in version 3.10.*

`statistics.linear_regression(x, y, /, *, proportional=False)`

Return the slope and intercept of [simple linear regression](https://en.wikipedia.org/wiki/Simple_linear_regression) [[https://en.wikipedia.org/wiki/Simple\\_linear\\_regression](https://en.wikipedia.org/wiki/Simple_linear_regression)] parameters estimated using ordinary least squares. Simple linear regression describes the relationship between an independent variable  $x$  and a dependent variable  $y$  in terms of this linear function:

$$y = \text{slope} * x + \text{intercept} + \text{noise}$$

where `slope` and `intercept` are the regression parameters that are estimated, and `noise` represents the variability of the data that was not explained by the linear regression (it is equal to the difference between predicted and actual values of the dependent variable).

Both inputs must be of the same length (no less than two), and the independent variable  $x$  cannot be constant; otherwise a `StatisticsError` is raised.

For example, we can use the [release dates of the Monty Python films](https://en.wikipedia.org/wiki/Monty_Python#Films) [[https://en.wikipedia.org/wiki/Monty\\_Python#Films](https://en.wikipedia.org/wiki/Monty_Python#Films)] to predict the cumulative number of Monty Python films that

would have been produced by 2019 assuming that they had kept the pace.

```
>>> year = [1971, 1975, 1979, 1982, 1983]
>>> films_total = [1, 2, 3, 4, 5]
>>> slope, intercept = linear_regression(year, films_total)
>>> round(slope * 2019 + intercept)
16
```

If *proportional* is true, the independent variable  $x$  and the dependent variable  $y$  are assumed to be directly proportional. The data is fit to a line passing through the origin. Since the *intercept* will always be 0.0, the underlying linear function simplifies to:

$$y = \text{slope} * x + \text{noise}$$

*New in version 3.10.*

*Changed in version 3.11:* Added support for *proportional*.

## Exceptions

A single exception is defined:

*exception* statistics.StatisticsError

Subclass of **ValueError** for statistics-related exceptions.

## NormalDist objects

**NormalDist** is a tool for creating and manipulating normal distributions of a **random variable** [<http://www.stat.yale.edu/Courses/1997-98/101/ranvar.htm>]. It is a class that treats the mean and standard deviation of data measurements as a single entity.

Normal distributions arise from the **Central Limit Theorem** [[https://en.wikipedia.org/wiki/Central\\_limit\\_theorem](https://en.wikipedia.org/wiki/Central_limit_theorem)] and have a wide range of applications in statistics.

*class* `statistics.NormalDist(mu=0.0, sigma=1.0)`

Returns a new *NormalDist* object where *mu* represents the [arithmetic mean](https://en.wikipedia.org/wiki/Arithmetic_mean) [https://en.wikipedia.org/wiki/Arithmetic\_mean] and *sigma* represents the [standard deviation](https://en.wikipedia.org/wiki/Standard_deviation) [https://en.wikipedia.org/wiki/Standard\_deviation].

If *sigma* is negative, raises **`StatisticsError`**.

**mean**

A read-only property for the [arithmetic mean](https://en.wikipedia.org/wiki/Arithmetic_mean) [https://en.wikipedia.org/wiki/Arithmetic\_mean] of a normal distribution.

**median**

A read-only property for the [median](https://en.wikipedia.org/wiki/Median) [https://en.wikipedia.org/wiki/Median] of a normal distribution.

**mode**

A read-only property for the [mode](https://en.wikipedia.org/wiki/Mode_(statistics)) [https://en.wikipedia.org/wiki/Mode\_(statistics)] of a normal distribution.

**stdev**

A read-only property for the [standard deviation](https://en.wikipedia.org/wiki/Standard_deviation) [https://en.wikipedia.org/wiki/Standard\_deviation] of a normal distribution.

**variance**

A read-only property for the [variance](https://en.wikipedia.org/wiki/Variance) [https://en.wikipedia.org/wiki/Variance] of a normal distribution. Equal to the square of the standard deviation.

*classmethod* `from_samples(data)`

Makes a normal distribution instance with *mu* and *sigma* parameters estimated from the *data* using **`fmean()`** and **`stdev()`**.

The *data* can be any [iterable](#) and should consist of

values that can be converted to type `float`. If *data* does not contain at least two elements, raises `StatisticsError` because it takes at least one point to estimate a central value and at least two points to estimate dispersion.

`samples(n, *, seed = None)`

Generates *n* random samples for a given mean and standard deviation. Returns a `list` of `float` values.

If *seed* is given, creates a new instance of the underlying random number generator. This is useful for creating reproducible results, even in a multi-threading context.

`pdf(x)`

Using a [probability density function \(pdf\)](https://en.wikipedia.org/wiki/Probability_density_function) [https://en.wikipedia.org/wiki/Probability\_density\_function], compute the relative likelihood that a random variable *X* will be near the given value *x*. Mathematically, it is the limit of the ratio  $P(x \leq X < x+dx) / dx$  as *dx* approaches zero.

The relative likelihood is computed as the probability of a sample occurring in a narrow range divided by the width of the range (hence the word “density”). Since the likelihood is relative to other points, its value can be greater than 1.0.

`cdf(x)`

Using a [cumulative distribution function \(cdf\)](https://en.wikipedia.org/wiki/Cumulative_distribution_function) [https://en.wikipedia.org/wiki/Cumulative\_distribution\_function], compute the probability that a random variable *X* will be less than or equal to *x*. Mathematically, it is written  $P(X \leq x)$ .

`inv_cdf(p)`

Compute the inverse cumulative distribution function, also known as the [quantile function](https://en.wikipedia.org/wiki/Quantile_function) [https://en.wikipedia.org/wiki/Quantile\_function]

en.wikipedia.org/wiki/Quantile\_function] or the [percent-point](https://web.archive.org/web/20190203145224/https://www.statisticshowto.datasciencecentral.com/inverse-distribution-function/) [https://web.archive.org/web/20190203145224/https://www.statisticshowto.datasciencecentral.com/inverse-distribution-function/] function. Mathematically, it is written  $x : P(X \leq x) = p$ .

Finds the value  $x$  of the random variable  $X$  such that the probability of the variable being less than or equal to that value equals the given probability  $p$ .

### `overlap(other)`

Measures the agreement between two normal probability distributions. Returns a value between 0.0 and 1.0 giving [the overlapping area for the two probability density functions](https://www.rasch.org/rmt/rmt101r.htm) [https://www.rasch.org/rmt/rmt101r.htm].

### `quantiles( $n=4$ )`

Divide the normal distribution into  $n$  continuous intervals with equal probability. Returns a list of  $(n - 1)$  cut points separating the intervals.

Set  $n$  to 4 for quartiles (the default). Set  $n$  to 10 for deciles. Set  $n$  to 100 for percentiles which gives the 99 cuts points that separate the normal distribution into 100 equal sized groups.

### `zscore( $x$ )`

Compute the [Standard Score](https://www.statisticshowto.com/probability-and-statistics/z-score/) [https://www.statisticshowto.com/probability-and-statistics/z-score/] describing  $x$  in terms of the number of standard deviations above or below the mean of the normal distribution:  $(x - \text{mean}) / \text{stdev}$ .

*New in version 3.9.*

Instances of `NormalDist` support addition, subtraction, multiplication and division by a constant. These operations are used for translation and scaling. For example:

```
>>> temperature_february = NormalDist(5, 2.5)
>>> temperature_february * (9/5) + 32
NormalDist(mu=41.0, sigma=4.5)
```

Dividing a constant by an instance of **NormalDist** is not supported because the result wouldn't be normally distributed.

Since normal distributions arise from additive effects of independent variables, it is possible to [add and subtract two independent normally distributed random variables](https://en.wikipedia.org/wiki/Sum_of_normally_distributed_random_variables) [https://en.wikipedia.org/wiki/Sum\_of\_normally\_distributed\_random\_variables] represented as instances of **NormalDist**. For example:

```
>>> birth_weights = NormalDist.from_samples([2.5, 3
>>> drug_effects = NormalDist(0.4, 0.15)
>>> combined = birth_weights + drug_effects
>>> round(combined.mean, 1)
3.1
>>> round(combined.stdev, 1)
0.5
```

*New in version 3.8.*

## **NormalDist** Examples and Recipes

**NormalDist** readily solves classic probability problems.

For example, given [historical data for SAT exams](https://nces.ed.gov/programs/digest/d17/tables/dt17_226.40.asp) [https://nces.ed.gov/programs/digest/d17/tables/dt17\_226.40.asp] showing that scores are normally distributed with a mean of 1060 and a standard deviation of 195, determine the percentage of students with test scores between 1100 and 1200, after rounding to the nearest whole number:

```
>>> sat = NormalDist(1060, 195)
>>> fraction = sat.cdf(1200 + 0.5) - sat.cdf(1100 - 0.5)
>>> round(fraction * 100.0, 1)
18.4
```

Find the [quartiles](https://en.wikipedia.org/wiki/Quartile) [https://en.wikipedia.org/wiki/Quartile] and [deciles](https://en.wikipedia.org/wiki/Decile) [https://en.wikipedia.org/wiki/Decile] for the SAT scores:

```
>>> list(map(round, sat.quantiles()))
[928, 1060, 1192]
>>> list(map(round, sat.quantiles(n=10)))
[810, 896, 958, 1011, 1060, 1109, 1162, 1224, 1310]
```

To estimate the distribution for a model that isn't easy to solve analytically, [NormalDist](https://en.wikipedia.org/wiki/Monte_Carlo_simulation) can generate input samples for a [Monte Carlo simulation](https://en.wikipedia.org/wiki/Monte_Carlo_simulation) [https://en.wikipedia.org/wiki/Monte\_Carlo\_method]:

```
>>> def model(x, y, z):
...     return (3*x + 7*x*y - 5*y) / (11 * z)
...
>>> n = 100_000
>>> X = NormalDist(10, 2.5).samples(n, seed=3652260728)
>>> Y = NormalDist(15, 1.75).samples(n, seed=4582495471)
>>> Z = NormalDist(50, 1.25).samples(n, seed=6582483453)
>>> quantiles(map(model, X, Y, Z))
[1.4591308524824727, 1.8035946855390597, 2.1750914472747]
```

Normal distributions can be used to approximate [Binomial distributions](https://mathworld.wolfram.com/BinomialDistribution.html) [https://mathworld.wolfram.com/BinomialDistribution.html] when the sample size is large and when the probability of a successful trial is near 50%.

For example, an open source conference has 750 attendees and two rooms with a 500 person capacity. There is a talk about Python and another about Ruby. In previous conferences, 65% of the attendees preferred to listen to Python talks. Assuming the population preferences haven't changed, what is the probability that the Python room will stay within its capacity limits?

```
>>> n = 750                # Sample size
>>> p = 0.65               # Preference for Python
>>> q = 1.0 - p            # Preference for Ruby
>>> k = 500                # Room capacity

>>> # Approximation using the cumulative normal distributio
```

```

>>> from math import sqrt
>>> round(NormalDist(mu=n*p, sigma=sqrt(n*p*q)).cdf(k +
0.8402

>>> # Solution using the cumulative binomial distribution
>>> from math import comb, fsum
>>> round(fsum(comb(n, r) * p**r * q**(n-r) for r in range(0, k+1))
0.8402

>>> # Approximation using a simulation
>>> from random import seed, choices
>>> seed(8675309)
>>> def trial():
...     return choices(('Python', 'Ruby'), (p, q), k=n)
>>> mean(trial() <= k for i in range(10_000))
0.8398

```

Normal distributions commonly arise in machine learning problems.

Wikipedia has a [nice example of a Naive Bayesian Classifier](https://en.wikipedia.org/wiki/Naive_Bayes_classifier#Person_classification) [https://en.wikipedia.org/wiki/Naive\_Bayes\_classifier#Person\_classification]. The challenge is to predict a person's gender from measurements of normally distributed features including height, weight, and foot size.

We're given a training dataset with measurements for eight people. The measurements are assumed to be normally distributed, so we summarize the data with **NormalDist**:

```

>>> height_male = NormalDist.from_samples([6, 5.92, 5.58])
>>> height_female = NormalDist.from_samples([5, 5.5, 5.4])
>>> weight_male = NormalDist.from_samples([180, 190, 170])
>>> weight_female = NormalDist.from_samples([100, 150, 140])
>>> foot_size_male = NormalDist.from_samples([12, 11, 12])
>>> foot_size_female = NormalDist.from_samples([6, 8, 7])

```

Next, we encounter a new person whose feature measurements are known but whose gender is unknown:

```

>>> ht = 6.0          # height

```

```
>>> wt = 130          # weight
>>> fs = 8            # foot size
```

Starting with a 50% [prior probability](https://en.wikipedia.org/wiki/Prior_probability) of being male or female, we compute the posterior as the prior times the product of likelihoods for the feature measurements given the gender:

```
>>> prior_male = 0.5
>>> prior_female = 0.5
>>> posterior_male = (prior_male * height_male.pdf(ht) *
...                   weight_male.pdf(wt) * foot_size_ma
>>> posterior_female = (prior_female * height_female.pdf
...                   weight_female.pdf(wt) * foot_siz
```

The final prediction goes to the largest posterior. This is known as the [maximum a posteriori](https://en.wikipedia.org/wiki/Maximum_a_posteriori_estimation) or MAP:

```
>>> 'male' if posterior_male > posterior_female else 'fe
'female'
```

# Functional Programming Modules

The modules described in this chapter provide functions and classes that support a functional programming style, and general operations on callables.

The following modules are documented in this chapter:

- **itertools** — Functions creating iterators for efficient looping
  - Itertool functions
  - Itertools Recipes
- **functools** — Higher-order functions and operations on callable objects
  - **partial** Objects
- **operator** — Standard operators as functions
  - Mapping Operators to Functions
  - In-place Operators

# itertools — Functions creating iterators for efficient looping

---

This module implements a number of [iterator](#) building blocks inspired by constructs from APL, Haskell, and SML. Each has been recast in a form suitable for Python.

The module standardizes a core set of fast, memory efficient tools that are useful by themselves or in combination. Together, they form an “iterator algebra” making it possible to construct specialized tools succinctly and efficiently in pure Python.

For instance, SML provides a tabulation tool: `tabulate(f)` which produces a sequence `f(0), f(1), ...`. The same effect can be achieved in Python by combining [map\(\)](#) and [count\(\)](#) to form `map(f, count())`.

These tools and their built-in counterparts also work well with the high-speed functions in the [operator](#) module. For example, the multiplication operator can be mapped across two vectors to form an efficient dot-product: `sum(starmap(operator.mul, zip(vec1, vec2, strict=True)))`.

Infinite iterators:

## Arguments

---

`start, step` — `step`; `start + 2*step, 1, 3, 14, ...`

---

`p0, p1, ..., pN` — `p0, p1, A, B, C, D, A, B, C, D, ...`

---

`elems, elem` — `elems, ...` endlessly or up to `n` times

---

Iterators terminating on the shortest input sequence:

## Arguments

---

accumulated results of other binary functions (specified via the optional *func* argument).

If *func* is supplied, it should be a function of two arguments. Elements of the input *iterable* may be any type that can be accepted as arguments to *func*. (For example, with the default operation of addition, elements may be any addable type including **Decimal** or **Fraction**.)

Usually, the number of elements output matches the input iterable. However, if the keyword argument *initial* is provided, the accumulation leads off with the *initial* value so that the output has one more element than the input iterable.

Roughly equivalent to:

```
def accumulate(iterable, func=operator.add, *, init=None):
    'Return running totals'
    # accumulate([1,2,3,4,5]) --> 1 3 6 10 15
    # accumulate([1,2,3,4,5], initial=100) --> 100
    # accumulate([1,2,3,4,5], operator.mul) --> 1 2
    it = iter(iterable)
    total = init
    if initial is None:
        try:
            total = next(it)
        except StopIteration:
            return
    yield total
    for element in it:
        total = func(total, element)
        yield total
```

There are a number of uses for the *func* argument. It can be set to **min()** for a running minimum, **max()** for a running maximum, or **operator.mul()** for a running product. Amortization tables can be built by accumulating interest and applying payments:

```
>>> data = [3, 4, 6, 2, 1, 9, 0, 7, 5, 8]
```

```
>>> list(accumulate(data, operator.mul))      # runn
[3, 12, 72, 144, 144, 1296, 0, 0, 0, 0]
>>> list(accumulate(data, max))              # runn
[3, 4, 6, 6, 6, 9, 9, 9, 9, 9]

# Amortize a 5% loan of 1000 with 4 annual payments
>>> cashflows = [1000, -90, -90, -90, -90]
>>> list(accumulate(cashflows, lambda bal, pmt: bal
[1000, 960.0, 918.0, 873.90000000000001, 827.5950000
```

See [functools.reduce\(\)](#) for a similar function that returns only the final accumulated value.

*New in version 3.2.*

*Changed in version 3.3:* Added the optional *func* parameter.

*Changed in version 3.8:* Added the optional *initial* parameter.

`itertools.chain(*iterables)`

Make an iterator that returns elements from the first iterable until it is exhausted, then proceeds to the next iterable, until all of the iterables are exhausted. Used for treating consecutive sequences as a single sequence. Roughly equivalent to:

```
def chain(*iterables):
    # chain('ABC', 'DEF') --> A B C D E F
    for it in iterables:
        for element in it:
            yield element
```

*classmethod* `chain.from_iterable(iterable)`

Alternate constructor for [chain\(\)](#). Gets chained inputs from a single iterable argument that is evaluated lazily. Roughly equivalent to:

```
def from_iterable(iterables):
    # chain.from_iterable(['ABC', 'DEF']) --> A B C
```

```

    for it in iterables:
        for element in it:
            yield element

```

`itertools.combinations(iterable, r)`

Return *r* length subsequences of elements from the input *iterable*.

The combination tuples are emitted in lexicographic ordering according to the order of the input *iterable*. So, if the input *iterable* is sorted, the output tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. So if the input elements are unique, there will be no repeated values in each combination.

Roughly equivalent to:

```

def combinations(iterable, r):
    # combinations('ABCD', 2) --> AB AC AD BC BD CD
    # combinations(range(4), 3) --> 012 013 023 123
    pool = tuple(iterable)
    n = len(pool)
    if r > n:
        return
    indices = list(range(r))
    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != i + n - r:
                break
        else:
            return
        indices[i] += 1
        for j in range(i+1, r):
            indices[j] = indices[j-1] + 1
        yield tuple(pool[i] for i in indices)

```

The code for `combinations()` can be also expressed as a subsequence of `permutations()` after filtering entries where the elements are not in sorted order (according to their position in the input pool):

```
def combinations(iterable, r):
    pool = tuple(iterable)
    n = len(pool)
    for indices in permutations(range(n), r):
        if sorted(indices) == list(indices):
            yield tuple(pool[i] for i in indices)
```

The number of items returned is  $n! / r! / (n-r)!$  when  $0 \leq r \leq n$  or zero when  $r > n$ .

`itertools.combinations_with_replacement(iterable, r)`

Return  $r$  length subsequences of elements from the input *iterable* allowing individual elements to be repeated more than once.

The combination tuples are emitted in lexicographic ordering according to the order of the input *iterable*. So, if the input *iterable* is sorted, the output tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. So if the input elements are unique, the generated combinations will also be unique.

Roughly equivalent to:

```
def combinations_with_replacement(iterable, r):
    # combinations_with_replacement('ABC', 2) --> A
    pool = tuple(iterable)
    n = len(pool)
    if not n and r:
        return
    indices = [0] * r
    yield tuple(pool[i] for i in indices)
    while True:
```

```

    for i in reversed(range(r)):
        if indices[i] != n - 1:
            break
    else:
        return
    indices[i:] = [indices[i] + 1] * (r - i)
    yield tuple(pool[i] for i in indices)

```

The code for `combinations_with_replacement()` can be also expressed as a subsequence of `product()` after filtering entries where the elements are not in sorted order (according to their position in the input pool):

```

def combinations_with_replacement(iterable, r):
    pool = tuple(iterable)
    n = len(pool)
    for indices in product(range(n), repeat=r):
        if sorted(indices) == list(indices):
            yield tuple(pool[i] for i in indices)

```

The number of items returned is  $(n+r-1)! / r! / (n-1)!$  when  $n > 0$ .

*New in version 3.1.*

`itertools.compress(data, selectors)`

Make an iterator that filters elements from *data* returning only those that have a corresponding element in *selectors* that evaluates to `True`. Stops when either the *data* or *selectors* iterables has been exhausted. Roughly equivalent to:

```

def compress(data, selectors):
    # compress('ABCDEF', [1,0,1,0,1,1]) --> A C E F
    return (d for d, s in zip(data, selectors) if s)

```

*New in version 3.1.*

`itertools.count(start=0, step=1)`

Make an iterator that returns evenly spaced values starting

with number *start*. Often used as an argument to `map()` to generate consecutive data points. Also, used with `zip()` to add sequence numbers. Roughly equivalent to:

```
def count(start=0, step=1):
    # count(10) --> 10 11 12 13 14 ...
    # count(2.5, 0.5) --> 2.5 3.0 3.5 ...
    n = start
    while True:
        yield n
        n += step
```

When counting with floating point numbers, better accuracy can sometimes be achieved by substituting multiplicative code such as: `(start + step * i for i in count())`.

*Changed in version 3.1:* Added *step* argument and allowed non-integer arguments.

### `itertools.cycle(iterable)`

Make an iterator returning elements from the iterable and saving a copy of each. When the iterable is exhausted, return elements from the saved copy. Repeats indefinitely. Roughly equivalent to:

```
def cycle(iterable):
    # cycle('ABCD') --> A B C D A B C D A B C D ...
    saved = []
    for element in iterable:
        yield element
        saved.append(element)
    while saved:
        for element in saved:
            yield element
```

Note, this member of the toolkit may require significant auxiliary storage (depending on the length of the iterable).

### `itertools.dropwhile(predicate, iterable)`

Make an iterator that drops elements from the iterable as long as the predicate is true; afterwards, returns every element. Note, the iterator does not produce *any* output until the predicate first becomes false, so it may have a lengthy start-up time. Roughly equivalent to:

```
def dropwhile(predicate, iterable):
    # dropwhile(lambda x: x<5, [1,4,6,4,1]) --> 6 4
    iterable = iter(iterable)
    for x in iterable:
        if not predicate(x):
            yield x
            break
    for x in iterable:
        yield x
```

### `itertools.filterfalse(predicate, iterable)`

Make an iterator that filters elements from iterable returning only those for which the predicate is false. If *predicate* is `None`, return the items that are false. Roughly equivalent to:

```
def filterfalse(predicate, iterable):
    # filterfalse(lambda x: x%2, range(10)) --> 0 2
    if predicate is None:
        predicate = bool
    for x in iterable:
        if not predicate(x):
            yield x
```

### `itertools.groupby(iterable, key=None)`

Make an iterator that returns consecutive keys and groups from the *iterable*. The *key* is a function computing a key value for each element. If not specified or is `None`, *key* defaults to an identity function and returns the element unchanged. Generally, the iterable needs to already be sorted on the same key function.

The operation of `groupby()` is similar to the `uniq` filter in Unix. It generates a break or new group every time the value of the key function changes (which is why it is usually necessary to have sorted the data using the same key function). That behavior differs from SQL's GROUP BY which aggregates common elements regardless of their input order.

The returned group is itself an iterator that shares the underlying iterable with `groupby()`. Because the source is shared, when the `groupby()` object is advanced, the previous group is no longer visible. So, if that data is needed later, it should be stored as a list:

```
groups = []
uniquekeys = []
data = sorted(data, key=keyfunc)
for k, g in groupby(data, keyfunc):
    groups.append(list(g))          # Store group iterator
    uniquekeys.append(k)
```

`groupby()` is roughly equivalent to:

```
class groupby:
    # [k for k, g in groupby('AAAABBBCCDAABBB')] --
    # [list(g) for k, g in groupby('AAAABBBCCD')] --

    def __init__(self, iterable, key=None):
        if key is None:
            key = lambda x: x
        self.keyfunc = key
        self.it = iter(iterable)
        self.tgtkey = self.currkey = self.currvalue = None

    def __iter__(self):
        return self

    def __next__(self):
        self.id = object()
        while self.currkey == self.tgtkey:
            self.currvalue = next(self.it)          # Exhaust group
```

```

        self.currkey = self.keyfunc(self.currvalue)
        self.tgtkey = self.currkey
        return (self.currkey, self._grouper(self.tgtkey, self.currvalue))

    def _grouper(self, tgtkey, id):
        while self.id is id and self.currkey == tgtkey:
            yield self.currvalue
            try:
                self.currvalue = next(self.it)
            except StopIteration:
                return
        self.currkey = self.keyfunc(self.currvalue)

```

`itertools.islice(iterable, stop)`

`itertools.islice(iterable, start, stop[, step])`

Make an iterator that returns selected elements from the iterable. If *start* is non-zero, then elements from the iterable are skipped until *start* is reached. Afterward, elements are returned consecutively unless *step* is set higher than one which results in items being skipped. If *stop* is `None`, then iteration continues until the iterator is exhausted, if at all; otherwise, it stops at the specified position.

If *start* is `None`, then iteration starts at zero. If *step* is `None`, then the step defaults to one.

Unlike regular slicing, `islice()` does not support negative values for *start*, *stop*, or *step*. Can be used to extract related fields from data where the internal structure has been flattened (for example, a multi-line report may list a name field on every third line).

Roughly equivalent to:

```

def islice(iterable, *args):
    # islice('ABCDEFGH', 2) --> A B
    # islice('ABCDEFGH', 2, 4) --> C D
    # islice('ABCDEFGH', 2, None) --> C D E F G
    # islice('ABCDEFGH', 0, None, 2) --> A C E G

```

```

s = slice(*args)
start, stop, step = s.start or 0, s.stop or sys
it = iter(range(start, stop, step))
try:
    nexti = next(it)
except StopIteration:
    # Consume *iterable* up to the *start* posi
    for i, element in zip(range(start), iterabl
        pass
    return
try:
    for i, element in enumerate(iterable):
        if i == nexti:
            yield element
            nexti = next(it)
except StopIteration:
    # Consume to *stop*.
    for i, element in zip(range(i + 1, stop), i
        pass

```

`itertools.pairwise(iterable)`

Return successive overlapping pairs taken from the input *iterable*.

The number of 2-tuples in the output iterator will be one fewer than the number of inputs. It will be empty if the input *iterable* has fewer than two values.

Roughly equivalent to:

```

def pairwise(iterable):
    # pairwise('ABCDEFGF') --> AB BC CD DE EF FG
    a, b = tee(iterable)
    next(b, None)
    return zip(a, b)

```

*New in version 3.10.*

`itertools.permutations(iterable, r=None)`

Return successive  $r$  length permutations of elements in the *iterable*.

If  $r$  is not specified or is `None`, then  $r$  defaults to the length of the *iterable* and all possible full-length permutations are generated.

The permutation tuples are emitted in lexicographic order according to the order of the input *iterable*. So, if the input *iterable* is sorted, the output tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. So if the input elements are unique, there will be no repeated values within a permutation.

Roughly equivalent to:

```
def permutations(iterable, r=None):
    # permutations('ABCD', 2) --> AB AC AD BA BC BD
    # permutations(range(3)) --> 012 021 102 120 201
    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    if r > n:
        return
    indices = list(range(n))
    cycles = list(range(n, n-r, -1))
    yield tuple(pool[i] for i in indices[:r])
    while n:
        for i in reversed(range(r)):
            cycles[i] -= 1
            if cycles[i] == 0:
                indices[i:] = indices[i+1:] + indices[0:1]
                cycles[i] = n - i
            else:
                j = cycles[i]
                indices[i], indices[-j] = indices[-j], indices[i]
                yield tuple(pool[i] for i in indices[:r])
                break
        n -= 1
```

```

else:
    return

```

The code for `permutations()` can be also expressed as a subsequence of `product()`, filtered to exclude entries with repeated elements (those from the same position in the input pool):

```

def permutations(iterable, r=None):
    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    for indices in product(range(n), repeat=r):
        if len(set(indices)) == r:
            yield tuple(pool[i] for i in indices)

```

The number of items returned is  $n! / (n-r)!$  when  $0 \leq r \leq n$  or zero when  $r > n$ .

`itertools.product(*iterables, repeat=1)`

Cartesian product of input iterables.

Roughly equivalent to nested for-loops in a generator expression. For example, `product(A, B)` returns the same as `((x,y) for x in A for y in B)`.

The nested loops cycle like an odometer with the rightmost element advancing on every iteration. This pattern creates a lexicographic ordering so that if the input's iterables are sorted, the product tuples are emitted in sorted order.

To compute the product of an iterable with itself, specify the number of repetitions with the optional `repeat` keyword argument. For example, `product(A, repeat=4)` means the same as `product(A, A, A, A)`.

This function is roughly equivalent to the following code, except that the actual implementation does not build up intermediate results in memory:

```
def product(*args, repeat=1):
    # product('ABCD', 'xy') --> Ax Ay Bx By Cx Cy Dx Dy
    # product(range(2), repeat=3) --> 000 001 010 011 100 101 110 111
    pools = [tuple(pool) for pool in args] * repeat
    result = [[]]
    for pool in pools:
        result = [x+[y] for x in result for y in pool]
    for prod in result:
        yield tuple(prod)
```

Before `product()` runs, it completely consumes the input iterables, keeping pools of values in memory to generate the products. Accordingly, it is only useful with finite inputs.

`itertools.repeat(object[, times])`

Make an iterator that returns *object* over and over again. Runs indefinitely unless the *times* argument is specified.

Roughly equivalent to:

```
def repeat(object, times=None):
    # repeat(10, 3) --> 10 10 10
    if times is None:
        while True:
            yield object
    else:
        for i in range(times):
            yield object
```

A common use for *repeat* is to supply a stream of constant values to *map* or *zip*:

```
>>> list(map(pow, range(10), repeat(2)))
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

`itertools.starmap(function, iterable)`

Make an iterator that computes the function using arguments obtained from the iterable. Used instead of `map()` when argument parameters are already grouped in tuples from a

single iterable (when the data has been “pre-zipped”).

The difference between `map()` and `starmap()` parallels the distinction between `function(a,b)` and `function(*c)`. Roughly equivalent to:

```
def starmap(function, iterable):
    # starmap(pow, [(2,5), (3,2), (10,3)]) --> 32 9
    for args in iterable:
        yield function(*args)
```

`itertools.takewhile(predicate, iterable)`

Make an iterator that returns elements from the iterable as long as the predicate is true. Roughly equivalent to:

```
def takewhile(predicate, iterable):
    # takewhile(lambda x: x<5, [1,4,6,4,1]) --> 1 4
    for x in iterable:
        if predicate(x):
            yield x
        else:
            break
```

`itertools.tee(iterable, n=2)`

Return *n* independent iterators from a single iterable.

The following Python code helps explain what *tee* does (although the actual implementation is more complex and uses only a single underlying FIFO queue):

```
def tee(iterable, n=2):
    it = iter(iterable)
    dequeues = [collections.deque() for i in range(n)]
    def gen(mydeque):
        while True:
            if not mydeque:                    # when the
                try:
                    newval = next(it)         # fetch a n
                except StopIteration:
                    return
```

```

        return
    for d in deque:
        # load it t
        d.append(newval)
    yield mydeque.popleft()
return tuple(gen(d) for d in deque)

```

Once a `tee()` has been created, the original *iterable* should not be used anywhere else; otherwise, the *iterable* could get advanced without the tee objects being informed.

tee iterators are not threadsafe. A `RuntimeError` may be raised when using simultaneously iterators returned by the same `tee()` call, even if the original *iterable* is threadsafe.

This itertools may require significant auxiliary storage (depending on how much temporary data needs to be stored). In general, if one iterator uses most or all of the data before another iterator starts, it is faster to use `list()` instead of `tee()`.

`itertools.zip_longest(*iterables, fillvalue=None)`

Make an iterator that aggregates elements from each of the iterables. If the iterables are of uneven length, missing values are filled-in with *fillvalue*. Iteration continues until the longest iterable is exhausted. Roughly equivalent to:

```

def zip_longest(*args, fillvalue=None):
    # zip_longest('ABCD', 'xy', fillvalue='-') -->
    iterators = [iter(it) for it in args]
    num_active = len(iterators)
    if not num_active:
        return
    while True:
        values = []
        for i, it in enumerate(iterators):
            try:
                value = next(it)
            except StopIteration:
                num_active -= 1

```

```
        if not num_active:
            return
        iterators[i] = repeat(fillvalue)
        value = fillvalue
        values.append(value)
    yield tuple(values)
```

If one of the iterables is potentially infinite, then the `zip_longest()` function should be wrapped with something that limits the number of calls (for example `islice()` or `takewhile()`). If not specified, *fillvalue* defaults to `None`.

## Itertools Recipes

This section shows recipes for creating an extended toolset using the existing itertools as building blocks.

The primary purpose of the itertools recipes is educational. The recipes show various ways of thinking about individual tools — for example, that `chain.from_iterable` is related to the concept of flattening. The recipes also give ideas about ways that the tools can be combined — for example, how `compress()` and `range()` can work together. The recipes also show patterns for using itertools with the **operator** and **collections** modules as well as with the built-in itertools such as `map()`, `filter()`, `reversed()`, and `enumerate()`.

A secondary purpose of the recipes is to serve as an incubator. The `accumulate()`, `compress()`, and `pairwise()` itertools started out as recipes. Currently, the `iter_index()` recipe is being tested to see whether it proves its worth.

Substantially all of these recipes and many, many others can be installed from the [more-itertools project](https://pypi.org/project/more-itertools/) [https://pypi.org/project/more-itertools/] found on the Python Package Index:

```
python -m pip install more-itertools
```

Many of the recipes offer the same high performance as the

underlying toolset. Superior memory performance is kept by processing elements one at a time rather than bringing the whole iterable into memory all at once. Code volume is kept small by linking the tools together in a functional style which helps eliminate temporary variables. High speed is retained by preferring “vectorized” building blocks over the use of for-loops and [generators](#) which incur interpreter overhead.

```
import collections
import math
import operator
import random
```

```
def take(n, iterable):
    "Return first n items of the iterable as a list"
    return list(islice(iterable, n))
```

```
def prepend(value, iterator):
    "Prepend a single value in front of an iterator"
    # prepend(1, [2, 3, 4]) --> 1 2 3 4
    return chain([value], iterator)
```

```
def tabulate(function, start=0):
    "Return function(0), function(1), ..."
    return map(function, count(start))
```

```
def tail(n, iterable):
    "Return an iterator over the last n items"
    # tail(3, 'ABCDEFGG') --> E F G
    return iter(collections.deque(iterable, maxlen=n))
```

```
def consume(iterator, n=None):
    "Advance the iterator n-steps ahead. If n is None, consume all."
    # Use functions that consume iterators at C speed.
    if n is None:
        # feed the entire iterator into a zero-length deque
        collections.deque(iterator, maxlen=0)
    else:
        # advance to the empty slice starting at position n

# functools — Higher-order functions and operations on callable objects

**Source code:** [Lib/functools.py](https://github.com/python/cpython/tree/3.11/Lib/functools.py) [https://github.com/python/cpython/tree/3.11/Lib/functools.py]

---

The **functools** module is for higher-order functions: functions that act on or return other functions. In general, any callable object can be treated as a function for the purposes of this module.

The **functools** module defines the following functions:

`@functools.cache(user_function)`

Simple lightweight unbounded function cache. Sometimes called “**memoize**” [https://en.wikipedia.org/wiki/Memoization].

Returns the same as `lru_cache(maxsize=None)`, creating a thin wrapper around a dictionary lookup for the function arguments. Because it never needs to evict old values, this is smaller and faster than `lru_cache()` with a size limit.

For example:

```
@cache
def factorial(n):
    return n * factorial(n-1) if n else 1

>>> factorial(10)          # no previously cached result
3628800
>>> factorial(5)           # just looks up cached value
120
>>> factorial(12)          # makes two new recursive calls
```

479001600

The cache is threadsafe so that the wrapped function can be used in multiple threads. This means that the underlying data structure will remain coherent during concurrent updates.

It is possible for the wrapped function to be called more than once if another thread makes an additional call before the initial call has been completed and cached.

*New in version 3.9.*

### `@functools.cached_property(func)`

Transform a method of a class into a property whose value is computed once and then cached as a normal attribute for the life of the instance. Similar to `property()`, with the addition of caching. Useful for expensive computed properties of instances that are otherwise effectively immutable.

Example:

```
class DataSet:

    def __init__(self, sequence_of_numbers):
        self._data = tuple(sequence_of_numbers)

    @cached_property
    def stdev(self):
        return statistics.stdev(self._data)
```

The mechanics of `cached_property()` are somewhat different from `property()`. A regular property blocks attribute writes unless a setter is defined. In contrast, a `cached_property` allows writes.

The `cached_property` decorator only runs on lookups and only when an attribute of the same name doesn't exist. When it does run, the `cached_property` writes to the attribute with the same name. Subsequent attribute reads and writes take precedence over the `cached_property` method and it works like

a normal attribute.

The cached value can be cleared by deleting the attribute. This allows the `cached_property` method to run again.

Note, this decorator interferes with the operation of [PEP 412](https://peps.python.org/pep-0412/) [https://peps.python.org/pep-0412/] key-sharing dictionaries. This means that instance dictionaries can take more space than usual.

Also, this decorator requires that the `__dict__` attribute on each instance be a mutable mapping. This means it will not work with some types, such as metaclasses (since the `__dict__` attributes on type instances are read-only proxies for the class namespace), and those that specify `__slots__` without including `__dict__` as one of the defined slots (as such classes don't provide a `__dict__` attribute at all).

If a mutable mapping is not available or if space-efficient key sharing is desired, an effect similar to `cached_property()` can also be achieved by stacking `property()` on top of `lru_cache()`. See [How do I cache method calls?](#) for more details on how this differs from `cached_property()`.

*New in version 3.8.*

`functools.cmp_to_key(func)`

Transform an old-style comparison function to a [key function](#). Used with tools that accept key functions (such as `sorted()`, `min()`, `max()`, `heapq.nlargest()`, `heapq.nsmallest()`, `itertools.groupby()`). This function is primarily used as a transition tool for programs being converted from Python 2 which supported the use of comparison functions.

A comparison function is any callable that accepts two arguments, compares them, and returns a negative number for less-than, zero for equality, or a positive number for greater-than. A key function is a callable that accepts one argument and returns another value to be used as the sort

key.

Example:

```
sorted(iterable, key=cmp_to_key(locale.strcoll)) #
```

For sorting examples and a brief sorting tutorial, see [Sorting HOW TO](#).

*New in version 3.2.*

`@functools.lru_cache(user_function)`

`@functools.lru_cache(maxsize=128, typed=False)`

Decorator to wrap a function with a memoizing callable that saves up to the *maxsize* most recent calls. It can save time when an expensive or I/O bound function is periodically called with the same arguments.

The cache is threadsafe so that the wrapped function can be used in multiple threads. This means that the underlying data structure will remain coherent during concurrent updates.

It is possible for the wrapped function to be called more than once if another thread makes an additional call before the initial call has been completed and cached.

Since a dictionary is used to cache results, the positional and keyword arguments to the function must be [hashable](#).

Distinct argument patterns may be considered to be distinct calls with separate cache entries. For example, `f(a=1, b=2)` and `f(b=2, a=1)` differ in their keyword argument order and may have two separate cache entries.

If *user\_function* is specified, it must be a callable. This allows the *lru\_cache* decorator to be applied directly to a user function, leaving the *maxsize* at its default value of 128:

```
@lru_cache
```

```
def count_vowels(sentence):
```

```
    return sum(sentence.count(vowel) for vowel in 'aeiouy')
```

If *maxsize* is set to `None`, the LRU feature is disabled and the cache can grow without bound.

If *typed* is set to `true`, function arguments of different types will be cached separately. If *typed* is `false`, the implementation will usually regard them as equivalent calls and only cache a single result. (Some types such as *str* and *int* may be cached separately even when *typed* is `false`.)

Note, type specificity applies only to the function's immediate arguments rather than their contents. The scalar arguments, `Decimal(42)` and `Fraction(42)` are be treated as distinct calls with distinct results. In contrast, the tuple arguments `('answer', Decimal(42))` and `('answer', Fraction(42))` are treated as equivalent.

The wrapped function is instrumented with a **`cache_parameters()`** function that returns a new `dict` showing the values for *maxsize* and *typed*. This is for information purposes only. Mutating the values has no effect.

To help measure the effectiveness of the cache and tune the *maxsize* parameter, the wrapped function is instrumented with a **`cache_info()`** function that returns a `named tuple` showing *hits*, *misses*, *maxsize* and *currsz*.

The decorator also provides a **`cache_clear()`** function for clearing or invalidating the cache.

The original underlying function is accessible through the **`__wrapped__`** attribute. This is useful for introspection, for bypassing the cache, or for rewrapping the function with a different cache.

The cache keeps references to the arguments and return values until they age out of the cache or until the cache is cleared.

If a method is cached, the `self` instance argument is included in the cache. See [How do I cache method calls?](#)

An **LRU (least recently used) cache** [[https://en.wikipedia.org/wiki/Cache\\_replacement\\_policies#Least\\_recently\\_used\\_\(LRU\)](https://en.wikipedia.org/wiki/Cache_replacement_policies#Least_recently_used_(LRU))] works best when the most recent calls are the best predictors of upcoming calls (for example, the most popular articles on a news server tend to change each day). The cache's size limit assures that the cache does not grow without bound on long-running processes such as web servers.

In general, the LRU cache should only be used when you want to reuse previously computed values. Accordingly, it doesn't make sense to cache functions with side-effects, functions that need to create distinct mutable objects on each call, or impure functions such as `time()` or `random()`.

Example of an LRU cache for static web content:

```
@lru_cache(maxsize=32)
def get_pep(num):
    'Retrieve text of a Python Enhancement Proposal
    resource = 'https://peps.python.org/pep-%04d/'
    try:
        with urllib.request.urlopen(resource) as s:
            return s.read()
    except urllib.error.HTTPError:
        return 'Not Found'

>>> for n in 8, 290, 308, 320, 8, 218, 320, 279, 28
...     pep = get_pep(n)
...     print(n, len(pep))

>>> get_pep.cache_info()
CacheInfo(hits=3, misses=8, maxsize=32, currsize=8)
```

Example of efficiently computing **Fibonacci numbers** [[https://en.wikipedia.org/wiki/Fibonacci\\_number](https://en.wikipedia.org/wiki/Fibonacci_number)] using a cache to implement a **dynamic programming** [[https://en.wikipedia.org/wiki/Dynamic\\_programming](https://en.wikipedia.org/wiki/Dynamic_programming)] technique:

```
@lru_cache(maxsize=None)
def fib(n):
```

```

    if n < 2:
        return n
    return fib(n-1) + fib(n-2)

>>> [fib(n) for n in range(16)]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610]

>>> fib.cache_info()
CacheInfo(hits=28, misses=16, maxsize=None, currsize=16)

```

*New in version 3.2.*

*Changed in version 3.3:* Added the *typed* option.

*Changed in version 3.8:* Added the *user\_function* option.

*New in version 3.9:* Added the function  
**cache\_parameters()**

## @functools.total\_ordering

Given a class defining one or more rich comparison ordering methods, this class decorator supplies the rest. This simplifies the effort involved in specifying all of the possible rich comparison operations:

The class must define one of `__lt__()`, `__le__()`, `__gt__()`, or `__ge__()`. In addition, the class should supply an `__eq__()` method.

For example:

```

@total_ordering
class Student:
    def __is_valid_operand(self, other):
        return (hasattr(other, "lastname") and
                hasattr(other, "firstname"))
    def __eq__(self, other):
        if not self.__is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()) ==
                (other.lastname.lower(), other.firstname.lower()))

```

```

        (other.lastname.lower(), other.firstname.lower()),
    )
    def __lt__(self, other):
        if not self._is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()),
                (other.lastname.lower(), other.firstname.lower()))

```

## Note

While this decorator makes it easy to create well behaved totally ordered types, it *does* come at the cost of slower execution and more complex stack traces for the derived comparison methods. If performance benchmarking indicates this is a bottleneck for a given application, implementing all six rich comparison methods instead is likely to provide an easy speed boost.

## Note

This decorator makes no attempt to override methods that have been declared in the class *or its superclasses*. Meaning that if a superclass defines a comparison operator, *total\_ordering* will not implement it again, even if the original method is abstract.

*New in version 3.2.*

*Changed in version 3.4:* Returning NotImplemented from the underlying comparison function for unrecognised types is now supported.

`functools.partial(func, /, *args, **keywords)`

Return a new **partial object** which when called will behave like *func* called with the positional arguments *args* and keyword arguments *keywords*. If more arguments are supplied to the call, they are appended to *args*. If additional keyword arguments are supplied, they extend and override *keywords*. Roughly equivalent to:

```
def partial(func, /, *args, **keywords):
    def newfunc(*fargs, **fkeywords):
        newkeywords = {**keywords, **fkeywords}
        return func(*args, *fargs, **newkeywords)
    newfunc.func = func
    newfunc.args = args
    newfunc.keywords = keywords
    return newfunc
```

The `partial()` is used for partial function application which “freezes” some portion of a function’s arguments and/or keywords resulting in a new object with a simplified signature. For example, `partial()` can be used to create a callable that behaves like the `int()` function where the *base* argument defaults to two:

```
>>> from functools import partial
>>> basetwo = partial(int, base=2)
>>> basetwo.__doc__ = 'Convert base 2 string to an
>>> basetwo('10010')
18
```

*class* `functools.partialmethod(func, /, *args, **keywords)`

Return a new `partialmethod` descriptor which behaves like `partial` except that it is designed to be used as a method definition rather than being directly callable.

*func* must be a `descriptor` or a callable (objects which are both, like normal functions, are handled as descriptors).

When *func* is a descriptor (such as a normal Python function, `classmethod()`, `staticmethod()`, `abstractmethod()` or another instance of `partialmethod`), calls to `__get__` are delegated to the underlying descriptor, and an appropriate `partial object` returned as the result.

When *func* is a non-descriptor callable, an appropriate bound method is created dynamically. This behaves like a normal Python function when used as a method: the *self* argument will be inserted as the first positional argument, even before

the *args* and *keywords* supplied to the `partialmethod` constructor.

Example:

```
>>> class Cell:
...     def __init__(self):
...         self._alive = False
...     @property
...     def alive(self):
...         return self._alive
...     def set_state(self, state):
...         self._alive = bool(state)
...     set_alive = partialmethod(set_state, True)
...     set_dead = partialmethod(set_state, False)
...
>>> c = Cell()
>>> c.alive
False
>>> c.set_alive()
>>> c.alive
True
```

*New in version 3.4.*

`functools.reduce(function, iterable[, initializer])`

Apply *function* of two arguments cumulatively to the items of *iterable*, from left to right, so as to reduce the iterable to a single value. For example, `reduce(lambda x, y: x+y, [1, 2, 3, 4, 5])` calculates  $((((1+2)+3)+4)+5)$ . The left argument, *x*, is the accumulated value and the right argument, *y*, is the update value from the *iterable*. If the optional *initializer* is present, it is placed before the items of the iterable in the calculation, and serves as a default when the iterable is empty. If *initializer* is not given and *iterable* contains only one item, the first item is returned.

Roughly equivalent to:

```
def reduce(function, iterable, initializer=None):
    it = iter(iterable)
    if initializer is None:
        value = next(it)
    else:
        value = initializer
    for element in it:
        value = function(value, element)
    return value
```

See [itertools.accumulate\(\)](#) for an iterator that yields all intermediate values.

### `@functools singledispatch`

Transform a function into a [single-dispatch generic function](#).

To define a generic function, decorate it with the `@singledispatch` decorator. When defining a function using `@singledispatch`, note that the dispatch happens on the type of the first argument:

```
>>> from functools import singledispatch
>>> @singledispatch
... def fun(arg, verbose=False):
...     if verbose:
...         print("Let me just say,", end=" ")
...     print(arg)
```

To add overloaded implementations to the function, use the **`register()`** attribute of the generic function, which can be used as a decorator. For functions annotated with types, the decorator will infer the type of the first argument automatically:

```
>>> @fun.register
... def _(arg: int, verbose=False):
...     if verbose:
...         print("Strength in numbers, eh?", end=" ")
...     print(arg)
... 
```

```
>>> @fun.register
... def _(arg: list, verbose=False):
...     if verbose:
...         print("Enumerate this:")
...     for i, elem in enumerate(arg):
...         print(i, elem)
```

`types.UnionType` and `typing.Union` can also be used:

```
>>> @fun.register
... def _(arg: int | float, verbose=False):
...     if verbose:
...         print("Strength in numbers, eh?", end="")
...         print(arg)
...
>>> from typing import Union
>>> @fun.register
... def _(arg: Union[list, set], verbose=False):
...     if verbose:
...         print("Enumerate this:")
...         for i, elem in enumerate(arg):
...             print(i, elem)
...
>>>
```

For code which doesn't use type annotations, the appropriate type argument can be passed explicitly to the decorator itself:

```
>>> @fun.register(complex)
... def _(arg, verbose=False):
...     if verbose:
...         print("Better than complicated.", end="")
...     print(arg.real, arg.imag)
... 
```

To enable registering `lambdas` and pre-existing functions, the `register()` attribute can also be used in a functional form:

```
>>> def nothing(arg, verbose=False):
...     print("Nothing.")
... 
```

```
>>> fun.register(type(None), nothing)
```

The **register()** attribute returns the undecorated function. This enables decorator stacking, **pickling**, and the creation of unit tests for each variant independently:

```
>>> @fun.register(float)
... @fun.register(Decimal)
... def fun_num(arg, verbose=False):
...     if verbose:
...         print("Half of your number:", end=" ")
...     print(arg / 2)
...
>>> fun_num is fun
False
```

When called, the generic function dispatches on the type of the first argument:

```
>>> fun("Hello, world.")
Hello, world.
>>> fun("test.", verbose=True)
Let me just say, test.
>>> fun(42, verbose=True)
Strength in numbers, eh? 42
>>> fun(['spam', 'spam', 'eggs', 'spam'], verbose=True)
Enumerate this:
0 spam
1 spam
2 eggs
3 spam
>>> fun(None)
Nothing.
>>> fun(1.23)
0.615
```

Where there is no registered implementation for a specific type, its method resolution order is used to find a more generic implementation. The original function decorated with **@singledispatch** is registered for the base **object** type,

which means it is used if no better implementation is found.

If an implementation is registered to an [abstract base class](#), virtual subclasses of the base class will be dispatched to that implementation:

```
>>> from collections.abc import Mapping
>>> @fun.register
... def _(arg: Mapping, verbose=False):
...     if verbose:
...         print("Keys & Values")
...     for key, value in arg.items():
...         print(key, "=>", value)
...
>>> fun({"a": "b"})
a => b
```

To check which implementation the generic function will choose for a given type, use the `dispatch()` attribute:

```
>>> fun.dispatch(float)
<function fun_num at 0x1035a2840>
>>> fun.dispatch(dict)      # note: default implement
<function fun at 0x103fe0000>
```

To access all registered implementations, use the read-only `registry` attribute:

```
>>> fun.registry.keys()
dict_keys([<class 'NoneType'>, <class 'int'>, <class 'decimal.Decimal'>, <class 'list'>, <class 'float'>])
>>> fun.registry[float]
<function fun_num at 0x1035a2840>
>>> fun.registry[object]
<function fun at 0x103fe0000>
```

*New in version 3.4.*

*Changed in version 3.7:* The **`register()`** attribute now

supports using type annotations.

*Changed in version 3.11:* The `register()` attribute now supports `types.UnionType` and `typing.Union` as type annotations.

*class* `functools.singledispatchmethod(func)`

Transform a method into a [single-dispatch generic function](#).

To define a generic method, decorate it with the `@singledispatchmethod` decorator. When defining a function using `@singledispatchmethod`, note that the dispatch happens on the type of the first non-*self* or non-*cls* argument:

```
class Negator:
    @singledispatchmethod
    def neg(self, arg):
        raise NotImplementedError("Cannot negate a")

    @neg.register
    def _(self, arg: int):
        return -arg

    @neg.register
    def _(self, arg: bool):
        return not arg
```

`@singledispatchmethod` supports nesting with other decorators such as `@classmethod`. Note that to allow for `dispatcher.register`, `singledispatchmethod` must be the *outer most* decorator. Here is the `Negator` class with the `neg` methods bound to the class, rather than an instance of the class:

```
class Negator:
    @singledispatchmethod
    @classmethod
    def neg(cls, arg):
        raise NotImplementedError("Cannot negate a")
```

```

@neg.register
@classmethod
def __(cls, arg: int):
    return -arg

@neg.register
@classmethod
def __(cls, arg: bool):
    return not arg

```

The same pattern can be used for other similar decorators: [@staticmethod](#), [@abstractmethod](#), and others.

*New in version 3.8.*

```

functools.update_wrapper(wrapper, wrapped,
    assigned = WRAPPER_ASSIGNMENTS,
    updated = WRAPPER_UPDATES)

```

Update a *wrapper* function to look like the *wrapped* function. The optional arguments are tuples to specify which attributes of the original function are assigned directly to the matching attributes on the wrapper function and which attributes of the wrapper function are updated with the corresponding attributes from the original function. The default values for these arguments are the module level constants `WRAPPER_ASSIGNMENTS` (which assigns to the wrapper function's `__module__`, `__name__`, `__qualname__`, `__annotations__` and `__doc__`, the documentation string) and `WRAPPER_UPDATES` (which updates the wrapper function's `__dict__`, i.e. the instance dictionary).

To allow access to the original function for introspection and other purposes (e.g. bypassing a caching decorator such as [lru\\_cache\(\)](#)), this function automatically adds a `__wrapped__` attribute to the wrapper that refers to the function being wrapped.

The main intended use for this function is in [decorator](#)

functions which wrap the decorated function and return the wrapper. If the wrapper function is not updated, the metadata of the returned function will reflect the wrapper definition rather than the original function definition, which is typically less than helpful.

`update_wrapper()` may be used with callables other than functions. Any attributes named in *assigned* or *updated* that are missing from the object being wrapped are ignored (i.e. this function will not attempt to set them on the wrapper function). `AttributeError` is still raised if the wrapper function itself is missing any attributes named in *updated*.

*New in version 3.2:* Automatic addition of the `__wrapped__` attribute.

*New in version 3.2:* Copying of the `__annotations__` attribute by default.

*Changed in version 3.2:* Missing attributes no longer trigger an `AttributeError`.

*Changed in version 3.4:* The `__wrapped__` attribute now always refers to the wrapped function, even if that function defined a `__wrapped__` attribute. (see [bpo-17482](https://bugs.python.org/issue/?action=redirect&bpo=17482) [https://bugs.python.org/issue/?action=redirect&bpo=17482])

`@functools.wraps(wrapped, assigned=WRAPPER_ASSIGNMENTS, updated=WRAPPER_UPDATES)`

This is a convenience function for invoking `update_wrapper()` as a function decorator when defining a wrapper function. It is equivalent to `partial(update_wrapper, wrapped=wrapped, assigned=assigned, updated=updated)`. For example:

```
>>> from functools import wraps
>>> def my_decorator(f):
...     @wraps(f)
...     def wrapper(*args, **kwargs):
...         print('Calling decorated function')
```

```

...         return f(*args, **kwargs)
...     return wrapper
...
>>> @my_decorator
... def example():
...     """Docstring"""
...     print('Called example function')
...
>>> example()
Calling decorated function
Called example function
>>> example.__name__
'example'
>>> example.__doc__
'Docstring'

```

Without the use of this decorator factory, the name of the `example` function would have been `'wrapper'`, and the docstring of the original `example()` would have been lost.

## partial Objects

**partial** objects are callable objects created by `partial()`. They have three read-only attributes:

`partial.func`

A callable object or function. Calls to the **partial** object will be forwarded to **func** with new arguments and keywords.

`partial.args`

The leftmost positional arguments that will be prepended to the positional arguments provided to a **partial** object call.

`partial.keywords`

The keyword arguments that will be supplied when the **partial** object is called.

**partial** objects are like **function** objects in that they are callable, weak referencable, and can have attributes. There are some important differences. For instance, the `__name__` and `__doc__` attributes are not created automatically. Also, **partial** objects defined in classes behave like static methods and do not transform into bound methods during instance attribute look-up.

# operator — Standard operators as functions

**Source code:** [Lib/operator.py](https://github.com/python/cpython/tree/3.11/Lib/operator.py) [https://github.com/python/cpython/tree/3.11/Lib/operator.py]

---

The `operator` module exports a set of efficient functions corresponding to the intrinsic operators of Python. For example, `operator.add(x, y)` is equivalent to the expression `x+y`. Many function names are those used for special methods, without the double underscores. For backward compatibility, many of these have a variant with the double underscores kept. The variants without the double underscores are preferred for clarity.

The functions fall into categories that perform object comparisons, logical operations, mathematical operations and sequence operations.

The object comparison functions are useful for all objects, and are named after the rich comparison operators they support:

```
operator.lt(a, b)
operator.le(a, b)
operator.eq(a, b)
operator.ne(a, b)
operator.ge(a, b)
operator.gt(a, b)
operator._lt_(a, b)
operator._le_(a, b)
operator._eq_(a, b)
operator._ne_(a, b)
operator._ge_(a, b)
```

`operator._gt_(a, b)`

Perform “rich comparisons” between *a* and *b*. Specifically, `lt(a, b)` is equivalent to `a < b`, `le(a, b)` is equivalent to `a <= b`, `eq(a, b)` is equivalent to `a == b`, `ne(a, b)` is equivalent to `a != b`, `gt(a, b)` is equivalent to `a > b` and `ge(a, b)` is equivalent to `a >= b`. Note that these functions can return any value, which may or may not be interpretable as a Boolean value. See [Comparisons](#) for more information about rich comparisons.

The logical operations are also generally applicable to all objects, and support truth tests, identity tests, and boolean operations:

`operator.not(obj)`

`operator._not_(obj)`

Return the outcome of `not obj`. (Note that there is no `__not__()` method for object instances; only the interpreter core defines this operation. The result is affected by the `__bool__()` and `__len__()` methods.)

`operator.truth(obj)`

Return `True` if *obj* is true, and `False` otherwise. This is equivalent to using the `bool` constructor.

`operator.is(a, b)`

Return `a is b`. Tests object identity.

`operator.is_not(a, b)`

Return `a is not b`. Tests object identity.

The mathematical and bitwise operations are the most numerous:

`operator.abs(obj)`

`operator._abs_(obj)`

Return the absolute value of *obj*.

`operator.add(a, b)`

`operator._add_(a, b)`

Return  $a + b$ , for  $a$  and  $b$  numbers.

`operator.and_(a, b)`

`operator._and_(a, b)`

Return the bitwise and of  $a$  and  $b$ .

`operator.floordiv(a, b)`

`operator._floordiv_(a, b)`

Return  $a // b$ .

`operator.index(a)`

`operator._index_(a)`

Return  $a$  converted to an integer. Equivalent to

`a.__index__()`.

*Changed in version 3.10:* The result always has exact type `int`. Previously, the result could have been an instance of a subclass of `int`.

`operator.inv(obj)`

`operator.invert(obj)`

`operator._inv_(obj)`

`operator._invert_(obj)`

Return the bitwise inverse of the number  $obj$ . This is equivalent to  $\sim obj$ .

`operator.lshift(a, b)`

`operator._lshift_(a, b)`

Return  $a$  shifted left by  $b$ .

`operator.mod(a, b)`

`operator._mod_(a, b)`

Return  $a \% b$ .

`operator.mul(a, b)`

`operator._mul_(a, b)`

Return  $a * b$ , for  $a$  and  $b$  numbers.

`operator.matmul(a, b)`

`operator._matmul_(a, b)`

Return  $a @ b$ .

*New in version 3.5.*

`operator.neg(obj)`

`operator._neg_(obj)`

Return  $obj$  negated ( $-obj$ ).

`operator.or_(a, b)`

`operator._or_(a, b)`

Return the bitwise or of  $a$  and  $b$ .

`operator.pos(obj)`

`operator._pos_(obj)`

Return  $obj$  positive ( $+obj$ ).

`operator.pow(a, b)`

`operator._pow_(a, b)`

Return  $a ** b$ , for  $a$  and  $b$  numbers.

`operator.rshift(a, b)`

`operator._rshift_(a, b)`

Return  $a$  shifted right by  $b$ .

`operator.sub(a, b)`

`operator._sub_(a, b)`

Return  $a - b$ .

`operator.truediv(a, b)`

`operator._truediv_(a, b)`

Return  $a / b$  where  $2/3$  is  $.66$  rather than  $0$ . This is also known as “true” division.

`operator.xor(a, b)`

`operator._xor_(a, b)`

Return the bitwise exclusive or of  $a$  and  $b$ .

Operations which work with sequences (some of them with mappings too) include:

`operator.concat(a, b)`

`operator._concat_(a, b)`

Return  $a + b$  for  $a$  and  $b$  sequences.

`operator.contains(a, b)`

`operator._contains_(a, b)`

Return the outcome of the test  $b \text{ in } a$ . Note the reversed operands.

`operator.countOf(a, b)`

Return the number of occurrences of  $b$  in  $a$ .

`operator.delitem(a, b)`

`operator._delitem_(a, b)`

Remove the value of  $a$  at index  $b$ .

`operatorgetitem(a, b)`

`operator._getitem_(a, b)`

Return the value of  $a$  at index  $b$ .

`operator.indexOf(a, b)`

Return the index of the first of occurrence of  $b$  in  $a$ .

`operator.setitem(a, b, c)`

`operator._setitem_(a, b, c)`

Set the value of *a* at index *b* to *c*.

`operator.length_hint(obj, default=0)`

Return an estimated length for the object *obj*. First try to return its actual length, then an estimate using `object.__length_hint__()`, and finally return the default value.

*New in version 3.4.*

The following operation works with callables:

`operator.call(obj, /, *args, **kwargs)`

`operator._call_(obj, /, *args, **kwargs)`

Return `obj(*args, **kwargs)`.

*New in version 3.11.*

The `operator` module also defines tools for generalized attribute and item lookups. These are useful for making fast field extractors as arguments for `map()`, `sorted()`, `itertools.groupby()`, or other functions that expect a function argument.

`operator.attrgetter(attr)`

`operator.attrgetter(*attrs)`

Return a callable object that fetches *attr* from its operand. If more than one attribute is requested, returns a tuple of attributes. The attribute names can also contain dots. For example:

- After `f = attrgetter('name')`, the call `f(b)` returns `b.name`.
- After `f = attrgetter('name', 'date')`, the call `f(b)` returns `(b.name, b.date)`.
- After `f = attrgetter('name.first', 'name.last')`, the call `f(b)` returns

```
(b.name.first, b.name.last).
```

Equivalent to:

```
def attrgetter(*items):
    if any(not isinstance(item, str) for item in items):
        raise TypeError('attribute name must be a string')
    if len(items) == 1:
        attr = items[0]
        def g(obj):
            return resolve_attr(obj, attr)
    else:
        def g(obj):
            return tuple(resolve_attr(obj, attr) for attr in items)
    return g

def resolve_attr(obj, attr):
    for name in attr.split("."):
        obj = getattr(obj, name)
    return obj
```

`operator.itemgetter(item)`

`operator.itemgetter(*items)`

Return a callable object that fetches *item* from its operand using the operand's `__getitem__()` method. If multiple items are specified, returns a tuple of lookup values. For example:

- After `f = itemgetter(2)`, the call `f(r)` returns `r[2]`.
- After `g = itemgetter(2, 5, 3)`, the call `g(r)` returns `(r[2], r[5], r[3])`.

Equivalent to:

```
def itemgetter(*items):
    if len(items) == 1:
        item = items[0]
        def g(obj):
            return obj[item]
```

```

        return obj[item]
    else:
        def g(obj):
            return tuple(obj[item] for item in item)
        return g

```

The items can be any type accepted by the operand's `__getitem__()` method. Dictionaries accept any [hashable](#) value. Lists, tuples, and strings accept an index or a slice:

```

>>> itemgetter(1)('ABCDEFGH')
'B'
>>> itemgetter(1, 3, 5)('ABCDEFGH')
('B', 'D', 'F')
>>> itemgetter(slice(2, None))('ABCDEFGH')
'CDEFG'
>>> soldier = dict(rank='captain', name='dotterbart')
>>> itemgetter('rank')(soldier)
'captain'

```

Example of using `itemgetter()` to retrieve specific fields from a tuple record:

```

>>> inventory = [('apple', 3), ('banana', 2), ('pear', 5)]
>>> getcount = itemgetter(1)
>>> list(map(getcount, inventory))
[3, 2, 5]
>>> sorted(inventory, key=getcount)
[('orange', 1), ('banana', 2), ('apple', 3), ('pear', 5)]

```

`operator.methodcaller(name, /, *args, **kwargs)`

Return a callable object that calls the method *name* on its operand. If additional arguments and/or keyword arguments are given, they will be given to the method as well. For example:

- After `f = methodcaller('name')`, the call `f(b)` returns `b.name()`.
- After `f = methodcaller('name', 'foo')`,

```
bar=1), the call f(b) returns b.name('foo',
bar=1).
```

Equivalent to:

```
def methodcaller(name, /, *args, **kwargs):
    def caller(obj):
        return getattr(obj, name)(*args, **kwargs)
    return caller
```

## Mapping Operators to Functions

This table shows how abstract operations correspond to operator symbols in the Python syntax and the functions in the [operator](#) module.

| Operation                  |
|----------------------------|
| Addition                   |
| Concatenation              |
| Concatenation (seq1, seq2) |
| Containment Test           |
| Containment Test (obj)     |
| Division                   |
| Division (a, b)            |
| Division (a, b)            |
| Bitwise And                |
| Bitwise Exclusive Or       |
| Bitwise Inversion          |
| Bitwise Or                 |
| Bitwise Or                 |
| Exponentiation             |
| Identity                   |
| Identity (a, b)            |
| Identity (a, b)            |
| Indexed Assignment         |
| Indexed Assignment (v)     |
| Indexed Deletion           |
| Indexed Deletion (k)       |
| Indexing                   |
| Indexing (obj, k)          |
| Left Shift                 |
| Left Shift (a, b)          |
| Modulo                     |
| Modulo (a, b)              |
| Multiplication             |
| Matrix Multiplication      |
| Negation (Arithmetic)      |
| Negation (Logical)         |
| Positive                   |
| Right Shift                |
| Right Shift (a, b)         |

~~Slice Assignment~~ `sequence[i, j], values)`

~~Slide Deletion~~ `sequence, slice(i, j))`

~~Slicing~~ `sequence[slice(i, j))`

~~String Formatting~~

~~Subtraction~~

~~Truth Test~~ `(j)`

~~Ordering~~ `(j)`

~~Ordering~~ `(j)`

~~Equality~~ `(b)`

~~Difference~~

~~Ordering~~ `(j)`

~~Ordering~~ `(j)`

## In-place Operators

Many operations have an “in-place” version. Listed below are functions providing a more primitive access to in-place operators than the usual syntax does; for example, the [statement](#) `x += y` is equivalent to `x = operator.iadd(x, y)`. Another way to put it is to say that `z = operator.iadd(x, y)` is equivalent to the compound statement `z = x; z += y`.

In those examples, note that when an in-place method is called, the computation and assignment are performed in two separate steps. The in-place functions listed below only do the first step, calling the in-place method. The second step, assignment, is not handled.

For immutable targets such as strings, numbers, and tuples, the updated value is computed, but not assigned back to the input variable:

```
>>> a = 'hello'
>>> iadd(a, ' world')
'hello world'
>>> a
'hello'
```

For mutable targets such as lists and dictionaries, the in-place method will perform the update, so no subsequent assignment is necessary:

```
>>> s = ['h', 'e', 'l', 'l', 'o']
>>> iadd(s, [' ', 'w', 'o', 'r', 'l', 'd'])
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
>>> s
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
```

`operator.iadd(a, b)`

`operator._iadd_(a, b)`

`a = iadd(a, b)` is equivalent to `a += b`.

`operator.iand(a, b)`

`operator._iand_(a, b)`

`a = iand(a, b)` is equivalent to `a &= b`.

`operator.iconcat(a, b)`

`operator._iconcat_(a, b)`

`a = iconcat(a, b)` is equivalent to `a += b` for *a* and *b* sequences.

`operator.ifloordiv(a, b)`

`operator._ifloordiv_(a, b)`

`a = ifloordiv(a, b)` is equivalent to `a //= b`.

`operator.ilshift(a, b)`

`operator._ilshift_(a, b)`

`a = ilshift(a, b)` is equivalent to `a <<= b`.

`operator.imod(a, b)`

`operator._imod_(a, b)`

`a = imod(a, b)` is equivalent to `a %= b`.

`operator.imul(a, b)`

`operator._imul_(a, b)`

`a = imul(a, b)` is equivalent to `a *= b`.

`operator.imatmul(a, b)`

`operator._imatmul_(a, b)`

`a = imatmul(a, b)` is equivalent to `a @= b`.

*New in version 3.5.*

`operator.ior(a, b)`

`operator._ior_(a, b)`

`a = ior(a, b)` is equivalent to `a |= b`.

`operator.ipow(a, b)`

`operator._ipow_(a, b)`

`a = ipow(a, b)` is equivalent to `a **= b`.

`operator.irshift(a, b)`

`operator._irshift_(a, b)`

`a = irshift(a, b)` is equivalent to `a >>= b`.

`operator.isub(a, b)`

`operator._isub_(a, b)`

`a = isub(a, b)` is equivalent to `a -= b`.

`operator.itruediv(a, b)`

`operator._itruediv_(a, b)`

`a = itrueidiv(a, b)` is equivalent to `a /= b`.

`operator.ixor(a, b)`

`operator._ixor_(a, b)`

`a = ixor(a, b)` is equivalent to `a ^= b`.

# File and Directory Access

The modules described in this chapter deal with disk files and directories. For example, there are modules for reading the properties of files, manipulating paths in a portable way, and creating temporary files. The full list of modules in this chapter is:

- **pathlib** — Object-oriented filesystem paths
  - Basic use
  - Pure paths
    - General properties
    - Operators
    - Accessing individual parts
    - Methods and properties
  - Concrete paths
    - Methods
  - Correspondence to tools in the **os** module
- **os.path** — Common pathname manipulations
- **fileinput** — Iterate over lines from multiple input streams
- **stat** — Interpreting **stat()** results
- **filecmp** — File and Directory Comparisons
  - The **dircmp** class
- **tempfile** — Generate temporary files and directories
  - Examples
  - Deprecated functions and variables
- **glob** — Unix style pathname pattern expansion
- **fnmatch** — Unix filename pattern matching
- **linecache** — Random access to text lines

- **shutil** — High-level file operations
  - Directory and files operations
    - Platform-dependent efficient copy operations
    - copytree example
    - rmtree example
  - Archiving operations
    - Archiving example
    - Archiving example with *base\_dir*
  - Querying the size of the output terminal

**See also**

**Module** **os**

Operating system interfaces, including functions to work with files at a lower level than Python [file objects](#).

**Module** **io**

Python's built-in I/O library, including both abstract classes and some concrete classes such as file I/O.

**Built-in function** **open()**

The standard way to open files for reading and writing with Python.

# pathlib — Object-oriented filesystem paths

*New in version 3.4.*

**Source code:** [Lib/pathlib.py](https://github.com/python/cpython/tree/3.11/Lib/pathlib.py) [https://github.com/python/cpython/tree/3.11/Lib/pathlib.py]

---

This module offers classes representing filesystem paths with semantics appropriate for different operating systems. Path classes are divided between **pure paths**, which provide purely computational operations without I/O, and **concrete paths**, which inherit from pure paths but also provide I/O operations.

If you've never used this module before or just aren't sure which class is right for your task, **Path** is most likely what you need. It instantiates a **concrete path** for the platform the code is running on.

Pure paths are useful in some special cases; for example:

1. If you want to manipulate Windows paths on a Unix machine (or vice versa). You cannot instantiate a **WindowsPath**

when running on Unix, but you can instantiate

**PureWindowsPath**.

2. You want to make sure that your code only manipulates paths without actually accessing the OS. In this case, instantiating one of the pure classes may be useful since those simply don't have any OS-accessing operations.

## See also

**PEP 428** [<https://peps.python.org/pep-0428/>]: The pathlib module – object-oriented filesystem paths.

## See also

For low-level path manipulation on strings, you can also use the **os.path** module.

# Basic use

Importing the main class:

```
>>> from pathlib import Path
```

Listing subdirectories:

```
>>> p = Path('.')
>>> [x for x in p.iterdir() if x.is_dir()]
[PosixPath('.hg'), PosixPath('docs'), PosixPath('dist'),
 PosixPath('__pycache__'), PosixPath('build')]
```

Listing Python source files in this directory tree:

```
>>> list(p.glob('**/*.py'))
[PosixPath('test_pathlib.py'), PosixPath('setup.py'),
 PosixPath('pathlib.py'), PosixPath('docs/conf.py'),
 PosixPath('build/lib/pathlib.py')]
```

Navigating inside a directory tree:

```
>>> p = Path('/etc')
>>> q = p / 'init.d' / 'reboot'
>>> q
PosixPath('/etc/init.d/reboot')
>>> q.resolve()
PosixPath('/etc/rc.d/init.d/halt')
```

Querying path properties:

```
>>> q.exists()
True
>>> q.is_dir()
False
```

Opening a file:

```
>>> with q.open() as f: f.readline()
...
'#!/bin/bash\n'
```

## Pure paths

Pure path objects provide path-handling operations which don't actually access a filesystem. There are three ways to access these classes, which we also call *flavours*:

`class pathlib.PurePath(*pathsegments)`

A generic class that represents the system's path flavour (instantiating it creates either a **PurePosixPath** or a **PureWindowsPath**):

```
>>> PurePath('setup.py')           # Running on a Unix machine
PurePosixPath('setup.py')
```

Each element of *pathsegments* can be either a string representing a path segment, an object implementing the **os.PathLike** interface which returns a string, or another path object:

```
>>> PurePath('foo', 'some/path', 'bar')
```

```
PurePosixPath('foo/some/path/bar')
>>> PurePath(Path('foo'), Path('bar'))
PurePosixPath('foo/bar')
```

When *pathsegments* is empty, the current directory is assumed:

```
>>> PurePath()
PurePosixPath('.')
```

If a segment is an absolute path, all previous segments are ignored (like `os.path.join()`):

```
>>> PurePath('/etc', '/usr', 'lib64')
PurePosixPath('/usr/lib64')
>>> PureWindowsPath('c:/Windows', 'd:bar')
PureWindowsPath('d:bar')
```

On Windows, the drive is not reset when a rooted relative path segment (e.g., `r'\foo'`) is encountered:

```
>>> PureWindowsPath('c:/Windows', '/Program Files')
PureWindowsPath('c:/Program Files')
```

Spurious slashes and single dots are collapsed, but double dots ('..') and leading double slashes ('//') are not, since this would change the meaning of a path for various reasons (e.g. symbolic links, UNC paths):

```
>>> PurePath('foo//bar')
PurePosixPath('foo/bar')
>>> PurePath('//foo/bar')
PurePosixPath('//foo/bar')
>>> PurePath('foo/./bar')
PurePosixPath('foo/bar')
>>> PurePath('foo/../bar')
PurePosixPath('foo/../bar')
```

(a naïve approach would make `PurePosixPath('foo/../bar')` equivalent to `PurePosixPath('bar')`, which is wrong if `foo` is a symbolic link to another directory)

Pure path objects implement the `os.PathLike` interface, allowing them to be used anywhere the interface is accepted.

*Changed in version 3.6:* Added support for the `os.PathLike` interface.

```
class pathlib.PurePosixPath(*pathsegments)
```

A subclass of `PurePath`, this path flavour represents non-Windows filesystem paths:

```
>>> PurePosixPath('/etc')
PurePosixPath('/etc')
```

*pathsegments* is specified similarly to `PurePath`.

```
class pathlib.PureWindowsPath(*pathsegments)
```

A subclass of `PurePath`, this path flavour represents Windows filesystem paths, including [UNC paths](https://en.wikipedia.org/wiki/Path_(computing)#UNC) [https://en.wikipedia.org/wiki/Path\_(computing)#UNC]:

```
>>> PureWindowsPath('c:/Program Files/')
PureWindowsPath('c:/Program Files')
>>> PureWindowsPath('//server/share/file')
PureWindowsPath('//server/share/file')
```

*pathsegments* is specified similarly to `PurePath`.

Regardless of the system you're running on, you can instantiate all of these classes, since they don't provide any operation that does system calls.

## General properties

Paths are immutable and [hashable](#). Paths of a same flavour are comparable and orderable. These properties respect the flavour's case-folding semantics:

```
>>> PurePosixPath('foo') == PurePosixPath('FOO')
False
```

```
>>> PureWindowsPath('foo') == PureWindowsPath('FOO')
True
>>> PureWindowsPath('FOO') in { PureWindowsPath('foo') }
True
>>> PureWindowsPath('C:') < PureWindowsPath('d:')
True
```

Paths of a different flavour compare unequal and cannot be ordered:

```
>>> PureWindowsPath('foo') == PurePosixPath('foo')
False
>>> PureWindowsPath('foo') < PurePosixPath('foo')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: '<' not supported between instances of 'PureW
```

## Operators

The slash operator helps create child paths, like [os.path.join\(\)](#). If the argument is an absolute path, the previous path is ignored. On Windows, the drive is not reset when the argument is a rooted relative path (e.g., `r'\foo'`):

```
>>> p = PurePath('/etc')
>>> p
PurePosixPath('/etc')
>>> p / 'init.d' / 'apache2'
PurePosixPath('/etc/init.d/apache2')
>>> q = PurePath('bin')
>>> '/usr' / q
PurePosixPath('/usr/bin')
>>> p / '/an_absolute_path'
PurePosixPath('/an_absolute_path')
>>> PureWindowsPath('c:/Windows', '/Program Files')
PureWindowsPath('c:/Program Files')
```

A path object can be used anywhere an object implementing [os.PathLike](#) is accepted:

```
>>> import os
>>> p = PurePath('/etc')
>>> os.fspath(p)
'/etc'
```

The string representation of a path is the raw filesystem path itself (in native form, e.g. with backslashes under Windows), which you can pass to any function taking a file path as a string:

```
>>> p = PurePath('/etc')
>>> str(p)
'/etc'
>>> p = PureWindowsPath('c:/Program Files')
>>> str(p)
'c:\\Program Files'
```

Similarly, calling **bytes** on a path gives the raw filesystem path as a bytes object, as encoded by **os.fsencode()**:

```
>>> bytes(p)
b'/etc'
```

## Note

Calling **bytes** is only recommended under Unix. Under Windows, the unicode form is the canonical representation of filesystem paths.

## Accessing individual parts

To access the individual “parts” (components) of a path, use the following property:

**PurePath.parts**

A tuple giving access to the path’s various components:

```
>>> p = PurePath('/usr/bin/python3')
>>> p.parts
('/', 'usr', 'bin', 'python3')
```

```
>>> p = PureWindowsPath('c:/Program Files/PSF')
>>> p.parts
('c:\\', 'Program Files', 'PSF')
```

(note how the drive and local root are regrouped in a single part)

## Methods and properties

Pure paths provide the following methods and properties:

### PurePath.drive

A string representing the drive letter or name, if any:

```
>>> PureWindowsPath('c:/Program Files/').drive
'c:'
>>> PureWindowsPath('/Program Files/').drive
''
>>> PurePosixPath('/etc').drive
''
```

UNC shares are also considered drives:

```
>>> PureWindowsPath('//host/share/foo.txt').drive
'\\\\\\host\\share'
```

### PurePath.root

A string representing the (local or global) root, if any:

```
>>> PureWindowsPath('c:/Program Files/').root
'\\'
>>> PureWindowsPath('c:Program Files/').root
''
>>> PurePosixPath('/etc').root
'/'
```

UNC shares always have a root:

```
>>> PureWindowsPath('//host/share').root
```

```
'\\'
```

If the path starts with more than two successive slashes, **PurePosixPath** collapses them:

```
>>> PurePosixPath('//etc').root
'/'
>>> PurePosixPath('///etc').root
'/'
>>> PurePosixPath('////etc').root
'/'
```

### Note

This behavior conforms to *The Open Group Base Specifications Issue 6*, paragraph [4.11 Pathname Resolution](https://pubs.opengroup.org/onlinepubs/009695399/basedefs/xbd_chap04.html#tag_04_11) [[https://pubs.opengroup.org/onlinepubs/009695399/basedefs/xbd\\_chap04.html#tag\\_04\\_11](https://pubs.opengroup.org/onlinepubs/009695399/basedefs/xbd_chap04.html#tag_04_11)]:

*“A pathname that begins with two successive slashes may be interpreted in an implementation-defined manner, although more than two leading slashes shall be treated as a single slash.”*

### PurePath.anchor

The concatenation of the drive and root:

```
>>> PureWindowsPath('c:/Program Files/').anchor
'c:\\'
>>> PureWindowsPath('c:Program Files/').anchor
'c:'
>>> PurePosixPath('/etc').anchor
'/'
>>> PureWindowsPath('//host/share').anchor
'\\\\\\host\\\\share\\'
```

### PurePath.parents

An immutable sequence providing access to the logical

ancestors of the path:

```
>>> p = PureWindowsPath('c:/foo/bar/setup.py')
>>> p.parents[0]
PureWindowsPath('c:/foo/bar')
>>> p.parents[1]
PureWindowsPath('c:/foo')
>>> p.parents[2]
PureWindowsPath('c:/')
```

*Changed in version 3.10:* The parents sequence now supports [slices](#) and negative index values.

## PurePath.parent

The logical parent of the path:

```
>>> p = PurePosixPath('/a/b/c/d')
>>> p.parent
PurePosixPath('/a/b/c')
```

You cannot go past an anchor, or empty path:

```
>>> p = PurePosixPath('/')
>>> p.parent
PurePosixPath('/')
>>> p = PurePosixPath('.')
>>> p.parent
PurePosixPath('.')
```

## Note

This is a purely lexical operation, hence the following behaviour:

```
>>> p = PurePosixPath('foo/..')
>>> p.parent
PurePosixPath('foo')
```

If you want to walk an arbitrary filesystem path upwards, it is recommended to first call [Path.resolve\(\)](#) so as to

resolve symlinks and eliminate "." components.

### PurePath.name

A string representing the final path component, excluding the drive and root, if any:

```
>>> PurePosixPath('my/library/setup.py').name
'setup.py'
```

UNC drive names are not considered:

```
>>> PureWindowsPath('//some/share/setup.py').name
'setup.py'
>>> PureWindowsPath('//some/share').name
''
```

### PurePath.suffix

The file extension of the final component, if any:

```
>>> PurePosixPath('my/library/setup.py').suffix
'.py'
>>> PurePosixPath('my/library.tar.gz').suffix
'.gz'
>>> PurePosixPath('my/library').suffix
''
```

### PurePath.suffixes

A list of the path's file extensions:

```
>>> PurePosixPath('my/library.tar.gar').suffixes
['.tar', '.gar']
>>> PurePosixPath('my/library.tar.gz').suffixes
['.tar', '.gz']
>>> PurePosixPath('my/library').suffixes
[]
```

### PurePath.stem

The final path component, without its suffix:

```
>>> PurePosixPath('my/library.tar.gz').stem
'library.tar'
>>> PurePosixPath('my/library.tar').stem
'library'
>>> PurePosixPath('my/library').stem
'library'
```

### PurePath.as\_posix()

Return a string representation of the path with forward slashes (/):

```
>>> p = PureWindowsPath('c:\\windows')
>>> str(p)
'c:\\windows'
>>> p.as_posix()
'c:/windows'
```

### PurePath.as\_uri()

Represent the path as a file URI. **ValueError** is raised if the path isn't absolute.

```
>>> p = PurePosixPath('/etc/passwd')
>>> p.as_uri()
'file:///etc/passwd'
>>> p = PureWindowsPath('c:/Windows')
>>> p.as_uri()
'file:///c:/Windows'
```

### PurePath.is\_absolute()

Return whether the path is absolute or not. A path is considered absolute if it has both a root and (if the flavour allows) a drive:

```
>>> PurePosixPath('/a/b').is_absolute()
True
>>> PurePosixPath('a/b').is_absolute()
```

False

```
>>> PureWindowsPath('c:/a/b').is_absolute()
True
>>> PureWindowsPath('/a/b').is_absolute()
False
>>> PureWindowsPath('c:').is_absolute()
False
>>> PureWindowsPath('//some/share').is_absolute()
True
```

**PurePath.is\_relative\_to(\*other)**

Return whether or not this path is relative to the *other* path.

```
>>> p = PurePath('/etc/passwd')
>>> p.is_relative_to('/etc')
True
>>> p.is_relative_to('/usr')
False
```

*New in version 3.9.*

**PurePath.is\_reserved()**

With **PureWindowsPath**, return `True` if the path is considered reserved under Windows, `False` otherwise. With **PurePosixPath**, `False` is always returned.

```
>>> PureWindowsPath('nul').is_reserved()
True
>>> PurePosixPath('nul').is_reserved()
False
```

File system calls on reserved paths can fail mysteriously or have unintended effects.

**PurePath.joinpath(\*other)**

Calling this method is equivalent to combining the path with each of the *other* arguments in turn:

```
>>> PurePosixPath('/etc').joinpath('passwd')
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath(PurePosixPath('p
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath('init.d', 'apach
PurePosixPath('/etc/init.d/apache2')
>>> PureWindowsPath('c:').joinpath('/Program Files'
PureWindowsPath('c:/Program Files')
```

### PurePath.match(*pattern*)

Match this path against the provided glob-style pattern.  
Return `True` if matching is successful, `False` otherwise.

If *pattern* is relative, the path can be either relative or absolute, and matching is done from the right:

```
>>> PurePath('a/b.py').match('*py')
True
>>> PurePath('/a/b/c.py').match('b/*py')
True
>>> PurePath('/a/b/c.py').match('a/*py')
False
```

If *pattern* is absolute, the path must be absolute, and the whole path must match:

```
>>> PurePath('/a.py').match('/*.py')
True
>>> PurePath('a/b.py').match('/*.py')
False
```

As with other methods, case-sensitivity follows platform defaults:

```
>>> PurePosixPath('b.py').match('*PY')
False
>>> PureWindowsPath('b.py').match('*PY')
True
```

## PurePath.relative\_to(\**other*)

Compute a version of this path relative to the path represented by *other*. If it's impossible, ValueError is raised:

```
>>> p = PurePosixPath('/etc/passwd')
>>> p.relative_to('/')
PurePosixPath('etc/passwd')
>>> p.relative_to('/etc')
PurePosixPath('passwd')
>>> p.relative_to('/usr')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 694, in relative_to
    .format(str(self), str(formatted)))
ValueError: '/etc/passwd' is not in the subpath of
```

NOTE: This function is part of **PurePath** and works with strings. It does not check or access the underlying file structure.

## PurePath.with\_name(*name*)

Return a new path with the **name** changed. If the original path doesn't have a name, ValueError is raised:

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_name('setup.py')
PureWindowsPath('c:/Downloads/setup.py')
>>> p = PureWindowsPath('c:/')
>>> p.with_name('setup.py')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/antoine/cpython/default/Lib/pathlib.py", line 694, in with_name
    raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

## PurePath.with\_stem(*stem*)

Return a new path with the **stem** changed. If the original path doesn't have a name, ValueError is raised:

```
>>> p = PureWindowsPath('c:/Downloads/draft.txt')
>>> p.with_stem('final')
PureWindowsPath('c:/Downloads/final.txt')
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_stem('lib')
PureWindowsPath('c:/Downloads/lib.gz')
>>> p = PureWindowsPath('c:/')
>>> p.with_stem('')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/antoine/cpython/default/Lib/pathlib.p
    return self.with_name(stem + self.suffix)
  File "/home/antoine/cpython/default/Lib/pathlib.p
    raise ValueError("%r has an empty name" % (self
ValueError: PureWindowsPath('c:/') has an empty nam
```

*New in version 3.9.*

### PurePath.with\_suffix(suffix)

Return a new path with the **suffix** changed. If the original path doesn't have a suffix, the new *suffix* is appended instead. If the *suffix* is an empty string, the original suffix is removed:

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_suffix('.bz2')
PureWindowsPath('c:/Downloads/pathlib.tar.bz2')
>>> p = PureWindowsPath('README')
>>> p.with_suffix('.txt')
PureWindowsPath('README.txt')
>>> p = PureWindowsPath('README.txt')
>>> p.with_suffix('')
PureWindowsPath('README')
```

## Concrete paths

Concrete paths are subclasses of the pure path classes. In addition to operations provided by the latter, they also provide methods to do system calls on path objects. There are three ways to instantiate

concrete paths:

`class pathlib.Path(*pathsegments)`

A subclass of `PurePath`, this class represents concrete paths of the system's path flavour (instantiating it creates either a `PosixPath` or a `WindowsPath`):

```
>>> Path('setup.py')
PosixPath('setup.py')
```

*pathsegments* is specified similarly to `PurePath`.

`class pathlib.PosixPath(*pathsegments)`

A subclass of `Path` and `PurePosixPath`, this class represents concrete non-Windows filesystem paths:

```
>>> PosixPath('/etc')
PosixPath('/etc')
```

*pathsegments* is specified similarly to `PurePath`.

`class pathlib.WindowsPath(*pathsegments)`

A subclass of `Path` and `PureWindowsPath`, this class represents concrete Windows filesystem paths:

```
>>> WindowsPath('c:/Program Files/')
WindowsPath('c:/Program Files')
```

*pathsegments* is specified similarly to `PurePath`.

You can only instantiate the class flavour that corresponds to your system (allowing system calls on non-compatible path flavours could lead to bugs or failures in your application):

```
>>> import os
>>> os.name
'posix'
>>> Path('setup.py')
PosixPath('setup.py')
```

```
>>> PosixPath('setup.py')
PosixPath('setup.py')
>>> WindowsPath('setup.py')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 798, in __new__
    % (cls.__name__,))
NotImplementedError: cannot instantiate 'WindowsPath' on
```

## Methods

Concrete paths provide the following methods in addition to pure paths methods. Many of these methods can raise an **OSError** if a system call fails (for example because the path doesn't exist).

*Changed in version 3.8:* **exists()**, **is\_dir()**, **is\_file()**, **is\_mount()**, **is\_symlink()**, **is\_block\_device()**, **is\_char\_device()**, **is\_fifo()**, **is\_socket()** now return False instead of raising an exception for paths that contain characters unrepresentable at the OS level.

*classmethod* Path.cwd()

Return a new path object representing the current directory (as returned by **os.getcwd()**):

```
>>> Path.cwd()
PosixPath('/home/antoine/pathlib')
```

*classmethod* Path.home()

Return a new path object representing the user's home directory (as returned by **os.path.expanduser()** with `~` construct). If the home directory can't be resolved, **RuntimeError** is raised.

```
>>> Path.home()
PosixPath('/home/antoine')
```

*New in version 3.5.*

`Path.stat(*, follow_symlinks=True)`

Return a `os.stat_result` object containing information about this path, like `os.stat()`. The result is looked up at each call to this method.

This method normally follows symlinks; to stat a symlink add the argument `follow_symlinks=False`, or use `lstat()`.

```
>>> p = Path('setup.py')
>>> p.stat().st_size
956
>>> p.stat().st_mtime
1327883547.852554
```

*Changed in version 3.10:* The `follow_symlinks` parameter was added.

`Path.chmod(mode, *, follow_symlinks=True)`

Change the file mode and permissions, like `os.chmod()`.

This method normally follows symlinks. Some Unix flavours support changing permissions on the symlink itself; on these platforms you may add the argument `follow_symlinks=False`, or use `lchmod()`.

```
>>> p = Path('setup.py')
>>> p.stat().st_mode
33277
>>> p.chmod(0o444)
>>> p.stat().st_mode
33060
```

*Changed in version 3.10:* The `follow_symlinks` parameter was added.

`Path.exists()`

Whether the path points to an existing file or directory:

```
>>> Path('.').exists()
```

```
True
>>> Path('setup.py').exists()
True
>>> Path('/etc').exists()
True
>>> Path('nonexistentfile').exists()
False
```

## Note

If the path points to a symlink, `exists()` returns whether the symlink *points to* an existing file or directory.

## Path.expanduser()

Return a new path with expanded `~` and `~user` constructs, as returned by `os.path.expanduser()`. If a home directory can't be resolved, `RuntimeError` is raised.

```
>>> p = PosixPath('~ /films/Monty Python')
>>> p.expanduser()
PosixPath('/home/eric/films/Monty Python')
```

*New in version 3.5.*

## Path.glob(pattern)

Glob the given relative *pattern* in the directory represented by this path, yielding all matching files (of any kind):

```
>>> sorted(Path('.').glob('*.*py'))
[PosixPath('pathlib.py'), PosixPath('setup.py'), Po
>>> sorted(Path('.').glob('*/*.*py'))
[PosixPath('docs/conf.py')]
```

Patterns are the same as for `fnmatch`, with the addition of `***` which means “this directory and all subdirectories, recursively”. In other words, it enables recursive globbing:

```
>>> sorted(Path('.').glob('***/*.*py'))
```

```
[PosixPath('build/lib/pathlib.py'),  
 PosixPath('docs/conf.py'),  
 PosixPath('pathlib.py'),  
 PosixPath('setup.py'),  
 PosixPath('test_pathlib.py')]
```

## Note

Using the “\*\*” pattern in large directory trees may consume an inordinate amount of time.

Raises an [auditing event](#) `pathlib.Path.glob` with arguments `self, pattern`.

*Changed in version 3.11:* Return only directories if *pattern* ends with a pathname components separator ([sep](#) or [altsep](#)).

## `Path.group()`

Return the name of the group owning the file. [KeyError](#) is raised if the file’s gid isn’t found in the system database.

## `Path.is_dir()`

Return `True` if the path points to a directory (or a symbolic link pointing to a directory), `False` if it points to another kind of file.

`False` is also returned if the path doesn’t exist or is a broken symlink; other errors (such as permission errors) are propagated.

## `Path.is_file()`

Return `True` if the path points to a regular file (or a symbolic link pointing to a regular file), `False` if it points to another kind of file.

`False` is also returned if the path doesn’t exist or is a broken symlink; other errors (such as permission errors) are propagated.

## Path.is\_mount()

Return `True` if the path is a *mount point*: a point in a file system where a different file system has been mounted. On POSIX, the function checks whether *path*'s parent, `path/..`, is on a different device than *path*, or whether `path/..` and *path* point to the same i-node on the same device — this should detect mount points for all Unix and POSIX variants. Not implemented on Windows.

*New in version 3.7.*

## Path.is\_symlink()

Return `True` if the path points to a symbolic link, `False` otherwise.

`False` is also returned if the path doesn't exist; other errors (such as permission errors) are propagated.

## Path.is\_socket()

Return `True` if the path points to a Unix socket (or a symbolic link pointing to a Unix socket), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

## Path.is\_fifo()

Return `True` if the path points to a FIFO (or a symbolic link pointing to a FIFO), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

## Path.is\_block\_device()

Return `True` if the path points to a block device (or a symbolic link pointing to a block device), `False` if it points

to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

### `Path.is_char_device()`

Return `True` if the path points to a character device (or a symbolic link pointing to a character device), `False` if it points to another kind of file.

`False` is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

### `Path.iterdir()`

When the path points to a directory, yield path objects of the directory contents:

```
>>> p = Path('docs')
>>> for child in p.iterdir(): child
...
PosixPath('docs/conf.py')
PosixPath('docs/_templates')
PosixPath('docs/make.bat')
PosixPath('docs/index.rst')
PosixPath('docs/_build')
PosixPath('docs/_static')
PosixPath('docs/Makefile')
```

The children are yielded in arbitrary order, and the special entries `'.'` and `'..'` are not included. If a file is removed from or added to the directory after creating the iterator, whether a path object for that file be included is unspecified.

### `Path.lchmod(mode)`

Like `Path.chmod()` but, if the path points to a symbolic link, the symbolic link's mode is changed rather than its target's.

## Path.lstat()

Like `Path.stat()` but, if the path points to a symbolic link, return the symbolic link's information rather than its target's.

## Path.mkdir(*mode=0o777, parents=False, exist\_ok=False*)

Create a new directory at this given path. If *mode* is given, it is combined with the process' `umask` value to determine the file mode and access flags. If the path already exists, `FileExistsError` is raised.

If *parents* is true, any missing parents of this path are created as needed; they are created with the default permissions without taking *mode* into account (mimicking the POSIX `mkdir -p` command).

If *parents* is false (the default), a missing parent raises `FileNotFoundError`.

If *exist\_ok* is false (the default), `FileExistsError` is raised if the target directory already exists.

If *exist\_ok* is true, `FileExistsError` exceptions will be ignored (same behavior as the POSIX `mkdir -p` command), but only if the last path component is not an existing non-directory file.

*Changed in version 3.5:* The *exist\_ok* parameter was added.

## Path.open(*mode='r', buffering=-1, encoding=None, errors=None, newline=None*)

Open the file pointed to by the path, like the built-in `open()` function does:

```
>>> p = Path('setup.py')
>>> with p.open() as f:
...     f.readline()
...
'#!/usr/bin/env python3\n'
```

## Path.owner()

Return the name of the user owning the file. `KeyError` is raised if the file's uid isn't found in the system database.

## Path.read\_bytes()

Return the binary contents of the pointed-to file as a bytes object:

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

*New in version 3.5.*

## Path.read\_text(encoding=None, errors=None)

Return the decoded contents of the pointed-to file as a string:

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

The file is opened and then closed. The optional parameters have the same meaning as in `open()`.

*New in version 3.5.*

## Path.readlink()

Return the path to which the symbolic link points (as returned by `os.readlink()`):

```
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.readlink()
PosixPath('setup.py')
```

*New in version 3.9.*

### `Path.rename(target)`

Rename this file or directory to the given *target*, and return a new Path instance pointing to *target*. On Unix, if *target* exists and is a file, it will be replaced silently if the user has permission. On Windows, if *target* exists, `FileExistsError` will be raised. *target* can be either a string or another path object:

```
>>> p = Path('foo')
>>> p.open('w').write('some text')
9
>>> target = Path('bar')
>>> p.rename(target)
PosixPath('bar')
>>> target.open().read()
'some text'
```

The target path may be absolute or relative. Relative paths are interpreted relative to the current working directory, *not* the directory of the Path object.

It is implemented in terms of `os.rename()` and gives the same guarantees.

*Changed in version 3.8:* Added return value, return the new Path instance.

### `Path.replace(target)`

Rename this file or directory to the given *target*, and return a new Path instance pointing to *target*. If *target* points to an existing file or empty directory, it will be unconditionally replaced.

The target path may be absolute or relative. Relative paths are interpreted relative to the current working directory, *not* the directory of the Path object.

*Changed in version 3.8:* Added return value, return the new Path instance.

### Path.absolute()

Make the path absolute, without normalization or resolving symlinks. Returns a new path object:

```
>>> p = Path('tests')
>>> p
PosixPath('tests')
>>> p.absolute()
PosixPath('/home/antoine/pathlib/tests')
```

### Path.resolve(strict=False)

Make the path absolute, resolving any symlinks. A new path object is returned:

```
>>> p = Path()
>>> p
PosixPath('.')
>>> p.resolve()
PosixPath('/home/antoine/pathlib')
```

“..” components are also eliminated (this is the only method to do so):

```
>>> p = Path('docs/../setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
```

If the path doesn't exist and *strict* is `True`, **FileNotFoundError** is raised. If *strict* is `False`, the path is resolved as far as possible and any remainder is appended without checking whether it exists. If an infinite loop is encountered along the resolution path, **RuntimeError** is raised.

*New in version 3.6:* The *strict* argument (pre-3.6 behavior is *strict*).

## Path.rglob(*pattern*)

This is like calling `Path.glob()` with “\*\*/” added in front of the given relative *pattern*:

```
>>> sorted(Path().rglob("*.py"))
[PosixPath('build/lib/pathlib.py'),
 PosixPath('docs/conf.py'),
 PosixPath('pathlib.py'),
 PosixPath('setup.py'),
 PosixPath('test_pathlib.py')]
```

Raises an `auditing event` `pathlib.Path.rglob` with arguments `self, pattern`.

*Changed in version 3.11:* Return only directories if *pattern* ends with a pathname components separator (`sep` or `altsep`).

## Path.rmdir()

Remove this directory. The directory must be empty.

## Path.samefile(*other\_path*)

Return whether this path points to the same file as *other\_path*, which can be either a Path object, or a string. The semantics are similar to `os.path.samefile()` and `os.path.samestat()`.

An `OSError` can be raised if either file cannot be accessed for some reason.

```
>>> p = Path('spam')
>>> q = Path('eggs')
>>> p.samefile(q)
False
>>> p.samefile('spam')
True
```

*New in version 3.5.*

## Path.symlink\_to(*target*, *target\_is\_directory=False*)

Make this path a symbolic link to *target*. Under Windows, *target\_is\_directory* must be true (default `False`) if the link's target is a directory. Under POSIX, *target\_is\_directory*'s value is ignored.

```
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
>>> p.stat().st_size
956
>>> p.lstat().st_size
8
```

### Note

The order of arguments (link, target) is the reverse of `os.symlink()`'s.

`Path.hardlink_to(target)`

Make this path a hard link to the same file as *target*.

### Note

The order of arguments (link, target) is the reverse of `os.link()`'s.

*New in version 3.10.*

`Path.link_to(target)`

Make *target* a hard link to this path.

### Warning

This function does not make this path a hard link to *target*, despite the implication of the function and argument names. The argument order (target, link) is the reverse of `Path.symlink_to()` and `Path.hardlink_to()`, but

matches that of `os.link()`.

*New in version 3.8.*

*Deprecated since version 3.10:* This method is deprecated in favor of `Path.hardlink_to()`, as the argument order of `Path.link_to()` does not match that of `Path.symlink_to()`.

`Path.touch(mode=0o666, exist_ok=True)`

Create a file at this given path. If *mode* is given, it is combined with the process' `umask` value to determine the file mode and access flags. If the file already exists, the function succeeds if *exist\_ok* is true (and its modification time is updated to the current time), otherwise `FileExistsError` is raised.

`Path.unlink(missing_ok=False)`

Remove this file or symbolic link. If the path points to a directory, use `Path.rmdir()` instead.

If *missing\_ok* is false (the default), `FileNotFoundError` is raised if the path does not exist.

If *missing\_ok* is true, `FileNotFoundError` exceptions will be ignored (same behavior as the POSIX `rm -f` command).

*Changed in version 3.8:* The *missing\_ok* parameter was added.

`Path.write_bytes(data)`

Open the file pointed to in bytes mode, write *data* to it, and close the file:

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

An existing file of the same name is overwritten.

*New in version 3.5.*

`Path.write_text(data, encoding=None, errors=None, newline=None)`

Open the file pointed to in text mode, write *data* to it, and close the file:

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

An existing file of the same name is overwritten. The optional parameters have the same meaning as in `open()`.

*New in version 3.5.*

*Changed in version 3.10:* The *newline* parameter was added.

## Correspondence to tools in the `os` module

Below is a table mapping various `os` functions to their corresponding `PurePath/Path` equivalent.

### Note

Not all pairs of functions/methods below are equivalent. Some of them, despite having some overlapping use-cases, have different semantics. They include `os.path.abspath()` and `Path.absolute()`, `os.path.relpath()` and `PurePath.relative_to()`.

| <code>pathlib</code>         | <code>os.path</code>            |
|------------------------------|---------------------------------|
| <code>Path.absolute()</code> | <code>os.path.abspath()</code>  |
| <code>Path.resolve()</code>  | <code>os.path.realpath()</code> |

```
Batbhmbd()
Batbkdkdi()
Batmahkdir$(X)
Bathenemen()
Batkepepta()
Batmdmddi()
Batmovex(k,())os.unlink()
Batgetwd(X)
Batpathieks$ts()
Batpathpendsn$(Path.home())
Bathistiddi()
Batpath_dsd()
Batpath_fsfil()
Batpath_symlink(X)
Batlink(link_to())
Bathymnk(link_to())
Batheadadmknk()
BarpBahhreepathveto() 2
Batstat(), Path.owner(), Path.group()
BarpBahhisabak$solute()
BarpBahhjgom(path)
BarpBahhbameame()
BarpBahhdpaneme()
Batpathsmefile()
BarpBahhsptenand(PurePath.suffix
```

## Footnotes

1

`os.path.abspath()` normalizes the resulting path, which may change its meaning in the presence of symlinks, while `Path.absolute()` does not.

2

`PurePath.relative_to()` requires `self` to be the subpath of the argument, but `os.path.relpath()` does not.

# os.path — Common pathname manipulations

**Source code:** [Lib/posixpath.py](https://github.com/python/cpython/tree/3.11/Lib/posixpath.py) [https://github.com/python/cpython/tree/3.11/Lib/posixpath.py] (for POSIX) and [Lib/ntpath.py](https://github.com/python/cpython/tree/3.11/Lib/ntpath.py) [https://github.com/python/cpython/tree/3.11/Lib/ntpath.py] (for Windows).

---

This module implements some useful functions on pathnames. To read or write files see [open\(\)](#), and for accessing the filesystem see the [os](#) module. The path parameters can be passed as strings, or bytes, or any object implementing the [os.PathLike](#) protocol.

Unlike a Unix shell, Python does not do any *automatic* path expansions. Functions such as [expanduser\(\)](#) and [expandvars\(\)](#) can be invoked explicitly when an application desires shell-like path expansion. (See also the [glob](#) module.)

## See also

The [pathlib](#) module offers high-level path objects.

## Note

All of these functions accept either only bytes or only string objects as their parameters. The result is an object of the same type, if a path or file name is returned.

## Note

Since different operating systems have different path name conventions, there are several versions of this module in the standard library. The [os.path](#) module is always the path module suitable for the operating system Python is running on,

and therefore usable for local paths. However, you can also import and use the individual modules if you want to manipulate a path that is *always* in one of the different formats. They all have the same interface:

- **posixpath** for UNIX-style paths
- **ntpath** for Windows paths

*Changed in version 3.8:* **exists()**, **lexists()**, **isdir()**, **isfile()**, **islink()**, and **ismount()** now return `False` instead of raising an exception for paths that contain characters or bytes unrepresentable at the OS level.

### `os.path.abspath(path)`

Return a normalized absolutized version of the pathname *path*. On most platforms, this is equivalent to calling the function **normpath()** as follows:

```
normpath(join(os.getcwd(), path)).
```

*Changed in version 3.6:* Accepts a [path-like object](#).

### `os.path.basename(path)`

Return the base name of pathname *path*. This is the second element of the pair returned by passing *path* to the function **split()**. Note that the result of this function is different from the Unix **basename** program; where **basename** for `'/foo/bar/'` returns `'bar'`, the **basename()** function returns an empty string `('')`.

*Changed in version 3.6:* Accepts a [path-like object](#).

### `os.path.commonpath(paths)`

Return the longest common sub-path of each pathname in the sequence *paths*. Raise **ValueError** if *paths* contain both absolute and relative pathnames, the *paths* are on the different drives or if *paths* is empty. Unlike **commonprefix()**, this returns a valid path.

[Availability](#): Unix, Windows.

*New in version 3.5.*

*Changed in version 3.6:* Accepts a sequence of [path-like objects](#).

`os.path.commonprefix(list)`

Return the longest path prefix (taken character-by-character) that is a prefix of all paths in *list*. If *list* is empty, return the empty string ('').

### Note

This function may return invalid paths because it works a character at a time. To obtain a valid path, see [commonpath\(\)](#).

```
>>> os.path.commonprefix(['/usr/lib', '/usr/local/
'/usr/l'
```

```
>>> os.path.commonpath(['/usr/lib', '/usr/local/li
'/usr'
```

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.dirname(path)`

Return the directory name of pathname *path*. This is the first element of the pair returned by passing *path* to the function [split\(\)](#).

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.exists(path)`

Return `True` if *path* refers to an existing path or an open file descriptor. Returns `False` for broken symbolic links. On some platforms, this function may return `False` if permission is not granted to execute [os.stat\(\)](#) on the requested file, even if the *path* physically exists.

*Changed in version 3.3:* *path* can now be an integer: `True` is

returned if it is an open file descriptor, `False` otherwise.

*Changed in version 3.6:* Accepts a [path-like object](#).

### `os.path.lexists(path)`

Return `True` if *path* refers to an existing path. Returns `True` for broken symbolic links. Equivalent to `exists()` on platforms lacking `os.lstat()`.

*Changed in version 3.6:* Accepts a [path-like object](#).

### `os.path.expanduser(path)`

On Unix and Windows, return the argument with an initial component of `~` or `~user` replaced by that *user*'s home directory.

On Unix, an initial `~` is replaced by the environment variable **HOME** if it is set; otherwise the current user's home directory is looked up in the password directory through the built-in module `pwd`. An initial `~user` is looked up directly in the password directory.

On Windows, **USERPROFILE** will be used if set, otherwise a combination of **HOMEPATH** and **HOMEDRIVE** will be used. An initial `~user` is handled by checking that the last directory component of the current user's home directory matches **USERNAME**, and replacing it if so.

If the expansion fails or if the path does not begin with a tilde, the path is returned unchanged.

*Changed in version 3.6:* Accepts a [path-like object](#).

*Changed in version 3.8:* No longer uses **HOME** on Windows.

### `os.path.expandvars(path)`

Return the argument with environment variables expanded. Substrings of the form `$name` or `${name}` are replaced by the value of environment variable *name*. Malformed variable

names and references to non-existing variables are left unchanged.

On Windows, `%name%` expansions are supported in addition to `$name` and `${name}`.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.getatime(path)`

Return the time of last access of *path*. The return value is a floating point number giving the number of seconds since the epoch (see the [time](#) module). Raise **OSError** if the file does not exist or is inaccessible.

`os.path.getmtime(path)`

Return the time of last modification of *path*. The return value is a floating point number giving the number of seconds since the epoch (see the [time](#) module). Raise **OSError** if the file does not exist or is inaccessible.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.getctime(path)`

Return the system's ctime which, on some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time for *path*. The return value is a number giving the number of seconds since the epoch (see the [time](#) module). Raise **OSError** if the file does not exist or is inaccessible.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.getsize(path)`

Return the size, in bytes, of *path*. Raise **OSError** if the file does not exist or is inaccessible.

*Changed in version 3.6:* Accepts a [path-like object](#).

### `os.path.isabs(path)`

Return `True` if *path* is an absolute pathname. On Unix, that means it begins with a slash, on Windows that it begins with a (back)slash after chopping off a potential drive letter.

*Changed in version 3.6:* Accepts a [path-like object](#).

### `os.path.isfile(path)`

Return `True` if *path* is an [existing](#) regular file. This follows symbolic links, so both `islink()` and `isfile()` can be true for the same path.

*Changed in version 3.6:* Accepts a [path-like object](#).

### `os.path.isdir(path)`

Return `True` if *path* is an [existing](#) directory. This follows symbolic links, so both `islink()` and `isdir()` can be true for the same path.

*Changed in version 3.6:* Accepts a [path-like object](#).

### `os.path.islink(path)`

Return `True` if *path* refers to an [existing](#) directory entry that is a symbolic link. Always `False` if symbolic links are not supported by the Python runtime.

*Changed in version 3.6:* Accepts a [path-like object](#).

### `os.path.ismount(path)`

Return `True` if pathname *path* is a *mount point*: a point in a file system where a different file system has been mounted. On POSIX, the function checks whether *path*'s parent, *path/..*, is on a different device than *path*, or whether *path/..* and *path* point to the same i-node on the same device — this should detect mount points for all Unix and POSIX variants. It is not able to reliably detect bind mounts on the same filesystem. On Windows, a drive letter root and a share UNC are always mount points, and for any other path

`GetVolumePathName` is called to see if it is different from the input path.

*New in version 3.4:* Support for detecting non-root mount points on Windows.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.join(path, *paths)`

Join one or more path segments intelligently. The return value is the concatenation of *path* and all members of *\*paths*, with exactly one directory separator following each non-empty part, except the last. That is, the result will only end in a separator if the last part is either empty or ends in a separator. If a segment is an absolute path (which on Windows requires both a drive and a root), then all previous segments are ignored and joining continues from the absolute path segment.

On Windows, the drive is not reset when a rooted path segment (e.g., `r'\foo'`) is encountered. If a segment is on a different drive or is an absolute path, all previous segments are ignored and the drive is reset. Note that since there is a current directory for each drive, `os.path.join("c:", "foo")` represents a path relative to the current directory on drive `C:` (`c:foo`), not `c:\foo`.

*Changed in version 3.6:* Accepts a [path-like object](#) for *path* and *paths*.

`os.path.normcase(path)`

Normalize the case of a pathname. On Windows, convert all characters in the pathname to lowercase, and also convert forward slashes to backward slashes. On other operating systems, return the path unchanged.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.normpath(path)`

Normalize a pathname by collapsing redundant separators and up-level references so that `A//B`, `A/B/`, `A/./B` and `A/foo/./B` all become `A/B`. This string manipulation may change the meaning of a path that contains symbolic links. On Windows, it converts forward slashes to backward slashes. To normalize case, use `normcase()`.

## Note

On POSIX systems, in accordance with [IEEE Std 1003.1 2013 Edition; 4.13 Pathname Resolution](https://pubs.opengroup.org/onlinepubs/9699919799/basedefs/V1_chap04.html#tag_04_13) [https://pubs.opengroup.org/onlinepubs/9699919799/basedefs/V1\_chap04.html#tag\_04\_13], if a pathname begins with exactly two slashes, the first component following the leading characters may be interpreted in an implementation-defined manner, although more than two leading characters shall be treated as a single character.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.realpath(path, *, strict=False)`

Return the canonical path of the specified filename, eliminating any symbolic links encountered in the path (if they are supported by the operating system).

If a path doesn't exist or a symlink loop is encountered, and `strict` is `True`, `OSError` is raised. If `strict` is `False`, the path is resolved as far as possible and any remainder is appended without checking whether it exists.

## Note

This function emulates the operating system's procedure

for making a path canonical, which differs slightly between Windows and UNIX with respect to how links and subsequent path components interact.

Operating system APIs make paths canonical as needed, so it's not normally necessary to call this function.

*Changed in version 3.6:* Accepts a [path-like object](#).

*Changed in version 3.8:* Symbolic links and junctions are now resolved on Windows.

*Changed in version 3.10:* The *strict* parameter was added.

`os.path.relpath(path, start=os.curdir)`

Return a relative filepath to *path* either from the current directory or from an optional *start* directory. This is a path computation: the filesystem is not accessed to confirm the existence or nature of *path* or *start*. On Windows, [ValueError](#) is raised when *path* and *start* are on different drives.

*start* defaults to [os.curdir](#).

[Availability](#): Unix, Windows.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.samefile(path1, path2)`

Return `True` if both pathname arguments refer to the same file or directory. This is determined by the device number and i-node number and raises an exception if an [os.stat\(\)](#) call on either pathname fails.

[Availability](#): Unix, Windows.

*Changed in version 3.2:* Added Windows support.

*Changed in version 3.4:* Windows now uses the same implementation as all other platforms.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.sameopenfile(fp1, fp2)`

Return `True` if the file descriptors *fp1* and *fp2* refer to the same file.

[Availability](#): Unix, Windows.

*Changed in version 3.2:* Added Windows support.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.samestat(stat1, stat2)`

Return `True` if the stat tuples *stat1* and *stat2* refer to the same file. These structures may have been returned by [os.fstat\(\)](#), [os.lstat\(\)](#), or [os.stat\(\)](#). This function implements the underlying comparison used by [samefile\(\)](#) and [sameopenfile\(\)](#).

[Availability](#): Unix, Windows.

*Changed in version 3.4:* Added Windows support.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.split(path)`

Split the pathname *path* into a pair, (*head*, *tail*) where *tail* is the last pathname component and *head* is everything leading up to that. The *tail* part will never contain a slash; if *path* ends in a slash, *tail* will be empty. If there is no slash in *path*, *head* will be empty. If *path* is empty, both *head* and *tail* are empty. Trailing slashes are stripped from *head* unless it is the root (one or more slashes only). In all cases, `join(head, tail)` returns a path to the same location as *path* (but the strings may differ). Also see the functions [dirname\(\)](#) and [basename\(\)](#).

*Changed in version 3.6:* Accepts a [path-like object](#).

## `os.path.splitdrive(path)`

Split the pathname *path* into a pair (*drive*, *tail*) where *drive* is either a mount point or the empty string. On systems which do not use drive specifications, *drive* will always be the empty string. In all cases, *drive* + *tail* will be the same as *path*.

On Windows, splits a pathname into drive/UNC sharepoint and relative path.

If the path contains a drive letter, *drive* will contain everything up to and including the colon:

```
>>> splitdrive("c:/dir")
("c:", "/dir")
```

If the path contains a UNC path, *drive* will contain the host name and share, up to but not including the fourth separator:

```
>>> splitdrive("//host/computer/dir")
("//host/computer", "/dir")
```

*Changed in version 3.6:* Accepts a [path-like object](#).

## `os.path.splitext(path)`

Split the pathname *path* into a pair (*root*, *ext*) such that *root* + *ext* == *path*, and the extension, *ext*, is empty or begins with a period and contains at most one period.

If the path contains no extension, *ext* will be '':

```
>>> splitext('bar')
('bar', '')
```

If the path contains an extension, then *ext* will be set to this extension, including the leading period. Note that previous periods will be ignored:

```
>>> splitext('foo.bar.exe')
('foo.bar', '.exe')
```

```
>>> splitext('/foo/bar.exe')  
('/foo/bar', '.exe')
```

Leading periods of the last component of the path are considered to be part of the root:

```
>>> splitext('.cshrc')  
('.cshrc', '')  
>>> splitext('/foo/....jpg')  
('/foo/....jpg', '')
```

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.path.supports_unicode_filenames`

True if arbitrary Unicode strings can be used as file names (within limitations imposed by the file system).

# fileinput — Iterate over lines from multiple input streams

**Source code:** [Lib/fileinput.py](https://github.com/python/cpython/tree/3.11/Lib/fileinput.py) [https://github.com/python/cpython/tree/3.11/Lib/fileinput.py]

---

This module implements a helper class and functions to quickly write a loop over standard input or a list of files. If you just want to read or write one file see [open\(\)](#).

The typical use is:

```
import fileinput
for line in fileinput.input(encoding="utf-8"):
    process(line)
```

This iterates over the lines of all files listed in `sys.argv[1:]`, defaulting to `sys.stdin` if the list is empty. If a filename is `'-'`, it is also replaced by `sys.stdin` and the optional arguments *mode* and *openhook* are ignored. To specify an alternative list of filenames, pass it as the first argument to [input\(\)](#). A single file name is also allowed.

All files are opened in text mode by default, but you can override this by specifying the *mode* parameter in the call to [input\(\)](#) or [FileInput](#). If an I/O error occurs during opening or reading a file, [OSError](#) is raised.

*Changed in version 3.3:* [IOError](#) used to be raised; it is now an alias of [OSError](#).

If `sys.stdin` is used more than once, the second and further use will return no lines, except perhaps for interactive use, or if it has been explicitly reset (e.g. using `sys.stdin.seek(0)`).

Empty files are opened and immediately closed; the only time their presence in the list of filenames is noticeable at all is when the last file opened is empty.

Lines are returned with any newlines intact, which means that the last line in a file may not have one.

You can control how files are opened by providing an opening hook via the `openhook` parameter to `fileinput.input()` or `FileInput()`. The hook must be a function that takes two arguments, *filename* and *mode*, and returns an accordingly opened file-like object. If *encoding* and/or *errors* are specified, they will be passed to the hook as additional keyword arguments. This module provides a `hook_compressed()` to support compressed files.

The following function is the primary interface of this module:

```
fileinput.input(files=None, inplace=False, backup='', *, mode='r',
openhook=None, encoding=None, errors=None)
```

Create an instance of the `FileInput` class. The instance will be used as global state for the functions of this module, and is also returned to use during iteration. The parameters to this function will be passed along to the constructor of the `FileInput` class.

The `FileInput` instance can be used as a context manager in the `with` statement. In this example, *input* is closed after the `with` statement is exited, even if an exception occurs:

```
with fileinput.input(files=('spam.txt', 'eggs.txt'))
    for line in f:
        process(line)
```

*Changed in version 3.2:* Can be used as a context manager.

*Changed in version 3.8:* The keyword parameters *mode* and *openhook* are now keyword-only.

*Changed in version 3.10:* The keyword-only parameter *encoding* and *errors* are added.

The following functions use the global state created by `fileinput.input()`; if there is no active state, `RuntimeError` is raised.

`fileinput.filename()`

Return the name of the file currently being read. Before the first line has been read, returns `None`.

`fileinput.fileno()`

Return the integer “file descriptor” for the current file. When no file is opened (before the first line and between files), returns `-1`.

`fileinput.lineno()`

Return the cumulative line number of the line that has just been read. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line.

`fileinput.filelineno()`

Return the line number in the current file. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line within the file.

`fileinput.isfirstline()`

Return `True` if the line just read is the first line of its file, otherwise return `False`.

`fileinput.isstdin()`

Return `True` if the last line was read from `sys.stdin`, otherwise return `False`.

`fileinput.nextfile()`

Close the current file so that the next iteration will read the first line from the next file (if any); lines not read from the file will not count towards the cumulative line count. The

filename is not changed until after the first line of the next file has been read. Before the first line has been read, this function has no effect; it cannot be used to skip the first file. After the last line of the last file has been read, this function has no effect.

```
fileinput.close()
```

Close the sequence.

The class which implements the sequence behavior provided by the module is available for subclassing as well:

```
class fileinput.FileInput(files=None, inplace=False, backup="", *,
mode='r', openhook=None, encoding=None, errors=None)
```

Class **FileInput** is the implementation; its methods **filename()**, **fileno()**, **lineno()**, **filelineno()**, **isfirstline()**, **isstdin()**, **nextfile()** and **close()** correspond to the functions of the same name in the module. In addition it is **iterable** and has a **readline()** method which returns the next input line. The sequence must be accessed in strictly sequential order; random access and **readline()** cannot be mixed.

With *mode* you can specify which file mode will be passed to **open()**. It must be one of 'r' and 'rb'.

The *openhook*, when given, must be a function that takes two arguments, *filename* and *mode*, and returns an accordingly opened file-like object. You cannot use *inplace* and *openhook* together.

You can specify *encoding* and *errors* that is passed to **open()** or *openhook*.

A **FileInput** instance can be used as a context manager in the **with** statement. In this example, *input* is closed after the **with** statement is exited, even if an exception occurs:

```
with FileInput(files=('spam.txt', 'eggs.txt')) as i:
    process(input)
```

*Changed in version 3.2:* Can be used as a context manager.

*Changed in version 3.8:* The keyword parameter *mode* and *openhook* are now keyword-only.

*Changed in version 3.10:* The keyword-only parameter *encoding* and *errors* are added.

*Changed in version 3.11:* The `'rU'` and `'U'` modes and the `__getitem__()` method have been removed.

**Optional in-place filtering:** if the keyword argument `inplace=True` is passed to `fileinput.input()` or to the `FileInput` constructor, the file is moved to a backup file and standard output is directed to the input file (if a file of the same name as the backup file already exists, it will be replaced silently). This makes it possible to write a filter that rewrites its input file in place. If the *backup* parameter is given (typically as `backup='.<some extension>'`), it specifies the extension for the backup file, and the backup file remains around; by default, the extension is `'.bak'` and it is deleted when the output file is closed. In-place filtering is disabled when standard input is read.

The two following opening hooks are provided by this module:

`fileinput.hook_compressed(filename, mode, *, encoding=None, errors=None)`

Transparently opens files compressed with gzip and bzip2 (recognized by the extensions `'.gz'` and `'.bz2'`) using the `gzip` and `bz2` modules. If the filename extension is not `'.gz'` or `'.bz2'`, the file is opened normally (ie, using `open()` without any decompression).

The *encoding* and *errors* values are passed to `io.TextIOWrapper` for compressed files and open for normal files.

Usage example: `fi =`

```
fileinput.FileInput(openhook=fileinput.hook_compressed,
encoding="utf-8")
```

*Changed in version 3.10:* The keyword-only parameter *encoding* and *errors* are added.

`fileinput.hook_encoded(encoding, errors=None)`

Returns a hook which opens each file with `open()`, using the given *encoding* and *errors* to read the file.

Usage example: `fi =`

```
fileinput.FileInput(openhook=fileinput.hook_encoded  
"surrogateescape"))
```

*Changed in version 3.6:* Added the optional *errors* parameter.

*Deprecated since version 3.10:* This function is deprecated since `fileinput.input()` and `FileInput` now have *encoding* and *errors* parameters.

# stat — Interpreting stat() results

**Source code:** [Lib/stat.py](https://github.com/python/cpython/tree/3.11/Lib/stat.py) [https://github.com/python/cpython/tree/3.11/Lib/stat.py]

---

The `stat` module defines constants and functions for interpreting the results of `os.stat()`, `os.fstat()` and `os.lstat()` (if they exist). For complete details about the `stat()`, `fstat()` and `lstat()` calls, consult the documentation for your system.

*Changed in version 3.4:* The `stat` module is backed by a C implementation.

The `stat` module defines the following functions to test for specific file types:

`stat.S_ISDIR(mode)`

Return non-zero if the mode is from a directory.

`stat.S_ISCHR(mode)`

Return non-zero if the mode is from a character special device file.

`stat.S_ISBLK(mode)`

Return non-zero if the mode is from a block special device file.

`stat.S_ISREG(mode)`

Return non-zero if the mode is from a regular file.

`stat.S_ISFIFO(mode)`

Return non-zero if the mode is from a FIFO (named pipe).

`stat.S_ISLNK(mode)`

Return non-zero if the mode is from a symbolic link.

`stat.S_ISSOCK(mode)`

Return non-zero if the mode is from a socket.

`stat.S_ISDOOR(mode)`

Return non-zero if the mode is from a door.

*New in version 3.4.*

`stat.S_ISPORT(mode)`

Return non-zero if the mode is from an event port.

*New in version 3.4.*

`stat.S_ISWHT(mode)`

Return non-zero if the mode is from a whiteout.

*New in version 3.4.*

Two additional functions are defined for more general manipulation of the file's mode:

`stat.S_IMODE(mode)`

Return the portion of the file's mode that can be set by `os.chmod()`—that is, the file's permission bits, plus the sticky bit, set-group-id, and set-user-id bits (on systems that support them).

`stat.S_IFMT(mode)`

Return the portion of the file's mode that describes the file type (used by the `S_IS*`() functions above).

Normally, you would use the `os.path.is*()` functions for

testing the type of a file; the functions here are useful when you are doing multiple tests of the same file and wish to avoid the overhead of the `stat()` system call for each test. These are also useful when checking for information about a file that isn't handled by `os.path`, like the tests for block and character devices.

Example:

```
import os, sys
from stat import *

def walktree(top, callback):
    '''recursively descend the directory tree rooted at
        calling the callback function for each regular fi

    for f in os.listdir(top):
        pathname = os.path.join(top, f)
        mode = os.lstat(pathname).st_mode
        if S_ISDIR(mode):
            # It's a directory, recurse into it
            walktree(pathname, callback)
        elif S_ISREG(mode):
            # It's a file, call the callback function
            callback(pathname)
        else:
            # Unknown file type, print a message
            print('Skipping %s' % pathname)

def visitfile(file):
    print('visiting', file)

if __name__ == '__main__':
    walktree(sys.argv[1], visitfile)
```

An additional utility function is provided to convert a file's mode in a human readable string:

`stat.filemode(mode)`

Convert a file's mode to a string of the form 'rwxrwxrwx'.

*New in version 3.3.*

*Changed in version 3.4:* The function supports `S_IFDOOR`, `S_IFPORT` and `S_IFWHT`.

All the variables below are simply symbolic indexes into the 10-tuple returned by `os.stat()`, `os.fstat()` or `os.lstat()`.

`stat.ST_MODE`

Inode protection mode.

`stat.ST_INO`

Inode number.

`stat.ST_DEV`

Device inode resides on.

`stat.ST_NLINK`

Number of links to the inode.

`stat.ST_UID`

User id of the owner.

`stat.ST_GID`

Group id of the owner.

`stat.ST_SIZE`

Size in bytes of a plain file; amount of data waiting on some special files.

`stat.ST_ATIME`

Time of last access.

`stat.ST_MTIME`

Time of last modification.

`stat.ST_CTIME`

The “ctime” as reported by the operating system. On some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time (see platform documentation for details).

The interpretation of “file size” changes according to the file type. For plain files this is the size of the file in bytes. For FIFOs and sockets under most flavors of Unix (including Linux in particular), the “size” is the number of bytes waiting to be read at the time of the call to `os.stat()`, `os.fstat()`, or `os.lstat()`; this can sometimes be useful, especially for polling one of these special files after a non-blocking open. The meaning of the size field for other character and block devices varies more, depending on the implementation of the underlying system call.

The variables below define the flags used in the `ST_MODE` field.

Use of the functions above is more portable than use of the first set of flags:

`stat.S_IFSOCK`

Socket.

`stat.S_IFLNK`

Symbolic link.

`stat.S_IFREG`

Regular file.

`stat.S_IFBLK`

Block device.

`stat.S_IFDIR`

Directory.

`stat.S_IFCHR`

Character device.

stat.S\_IFIFO  
FIFO.

stat.S\_IFDOOR  
Door.

*New in version 3.4.*

stat.S\_IFPORT  
Event port.

*New in version 3.4.*

stat.S\_IFWHT  
Whiteout.

*New in version 3.4.*

## Note

`S_IFDOOR`, `S_IFPORT` or `S_IFWHT` are defined as 0 when the platform does not have support for the file types.

The following flags can also be used in the *mode* argument of `os.chmod()`:

stat.S\_ISUID  
Set UID bit.

stat.S\_ISGID  
Set-group-ID bit. This bit has several special uses. For a directory it indicates that BSD semantics is to be used for that directory: files created there inherit their group ID from the directory, not from the effective group ID of the creating process, and directories created there will also get the `S_ISGID` bit set. For a file that does not have the group execution bit (`S_IXGRP`) set, the set-group-ID bit indicates mandatory file/record locking (see also `S_ENFMT`).

stat.S\_ISVTX

Sticky bit. When this bit is set on a directory it means that a file in that directory can be renamed or deleted only by the owner of the file, by the owner of the directory, or by a privileged process.

stat.S\_IRWXU

Mask for file owner permissions.

stat.S\_IRUSR

Owner has read permission.

stat.S\_IWUSR

Owner has write permission.

stat.S\_IXUSR

Owner has execute permission.

stat.S\_IRWXG

Mask for group permissions.

stat.S\_IRGRP

Group has read permission.

stat.S\_IWGRP

Group has write permission.

stat.S\_IXGRP

Group has execute permission.

stat.S\_IRWXO

Mask for permissions for others (not in group).

stat.S\_IROTH

Others have read permission.

stat.S\_IWOTH

Others have write permission.

stat.S\_IXOTH

Others have execute permission.

stat.S\_ENFMT

System V file locking enforcement. This flag is shared with [S\\_ISGID](#): file/record locking is enforced on files that do not have the group execution bit ([S\\_IXGRP](#)) set.

stat.S\_IREAD

Unix V7 synonym for [S\\_IRUSR](#).

stat.S\_IWRITE

Unix V7 synonym for [S\\_IWUSR](#).

stat.S\_IEXEC

Unix V7 synonym for [S\\_IXUSR](#).

The following flags can be used in the *flags* argument of [os.chflags\(\)](#):

stat.UF\_NODUMP

Do not dump the file.

stat.UF\_IMMUTABLE

The file may not be changed.

stat.UF\_APPEND

The file may only be appended to.

stat.UF\_OPAQUE

The directory is opaque when viewed through a union stack.

stat.UF\_NOUNLINK

The file may not be renamed or deleted.

stat.UF\_COMPRESSED

The file is stored compressed (macOS 10.6+).

stat.UF\_HIDDEN

The file should not be displayed in a GUI (macOS 10.5+).

stat.SF\_ARCHIVED

The file may be archived.

stat.SF\_IMMUTABLE

The file may not be changed.

stat.SF\_APPEND

The file may only be appended to.

stat.SF\_NOUNLINK

The file may not be renamed or deleted.

stat.SF\_SNAPSHOT

The file is a snapshot file.

See the \*BSD or macOS systems man page [chflags\(2\)](#) for more information.

On Windows, the following file attribute constants are available for use when testing bits in the `st_file_attributes` member returned by `os.stat()`. See the [Windows API documentation](https://msdn.microsoft.com/en-us/library/windows/desktop/gg258117.aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/gg258117.aspx] for more detail on the meaning of these constants.

stat.FILE\_ATTRIBUTE\_ARCHIVE

stat.FILE\_ATTRIBUTE\_COMPRESSED

stat.FILE\_ATTRIBUTE\_DEVICE

stat.FILE\_ATTRIBUTE\_DIRECTORY

stat.FILE\_ATTRIBUTE\_ENCRYPTED

stat.FILE\_ATTRIBUTE\_HIDDEN

stat.FILE\_ATTRIBUTE\_INTEGRITY\_STREAM  
stat.FILE\_ATTRIBUTE\_NORMAL  
stat.FILE\_ATTRIBUTE\_NOT\_CONTENT\_INDEXED  
stat.FILE\_ATTRIBUTE\_NO\_SCRUB\_DATA  
stat.FILE\_ATTRIBUTE\_OFFLINE  
stat.FILE\_ATTRIBUTE\_READONLY  
stat.FILE\_ATTRIBUTE\_REPARSE\_POINT  
stat.FILE\_ATTRIBUTE\_SPARSE\_FILE  
stat.FILE\_ATTRIBUTE\_SYSTEM  
stat.FILE\_ATTRIBUTE\_TEMPORARY  
stat.FILE\_ATTRIBUTE\_VIRTUAL

*New in version 3.5.*

On Windows, the following constants are available for comparing against the `st_reparse_tag` member returned by `os.lstat()`. These are well-known constants, but are not an exhaustive list.

stat.IO\_REPARSE\_TAG\_SYMLINK  
stat.IO\_REPARSE\_TAG\_MOUNT\_POINT  
stat.IO\_REPARSE\_TAG\_APPEXECLINK

*New in version 3.8.*

# filecmp — File and Directory Comparisons

**Source code:** [Lib/filecmp.py](https://github.com/python/cpython/tree/3.11/Lib/filecmp.py) [https://github.com/python/cpython/tree/3.11/Lib/filecmp.py]

---

The `filecmp` module defines functions to compare files and directories, with various optional time/correctness trade-offs. For comparing files, see also the `difflib` module.

The `filecmp` module defines the following functions:

`filecmp.cmp(f1, f2, shallow = True)`

Compare the files named *f1* and *f2*, returning `True` if they seem equal, `False` otherwise.

If *shallow* is true and the `os.stat()` signatures (file type, size, and modification time) of both files are identical, the files are taken to be equal.

Otherwise, the files are treated as different if their sizes or contents differ.

Note that no external programs are called from this function, giving it portability and efficiency.

This function uses a cache for past comparisons and the results, with cache entries invalidated if the `os.stat()` information for the file changes. The entire cache may be cleared using `clear_cache()`.

`filecmp.cmpfiles(dir1, dir2, common, shallow = True)`

Compare the files in the two directories *dir1* and *dir2* whose names are given by *common*.

Returns three lists of file names: *match*, *mismatch*, *errors*. *match* contains the list of files that match, *mismatch* contains the names of those that don't, and *errors* lists the names of files which could not be compared. Files are listed in *errors* if they don't exist in one of the directories, the user lacks permission to read them or if the comparison could not be done for some other reason.

The *shallow* parameter has the same meaning and default value as for `filecmp.cmp()`.

For example, `cmpfiles('a', 'b', ['c', 'd/e'])` will compare `a/c` with `b/c` and `a/d/e` with `b/d/e`. `'c'` and `'d/e'` will each be in one of the three returned lists.

`filecmp.clear_cache()`

Clear the filecmp cache. This may be useful if a file is compared so quickly after it is modified that it is within the mtime resolution of the underlying filesystem.

*New in version 3.4.*

## The `dircmp` class

`class filecmp.dircmp(a, b, ignore=None, hide=None)`

Construct a new directory comparison object, to compare the directories *a* and *b*. *ignore* is a list of names to ignore, and defaults to `filecmp.DEFAULT_IGNORES`. *hide* is a list of names to hide, and defaults to `[os.curdir, os.pardir]`.

The `dircmp` class compares files by doing *shallow* comparisons as described for `filecmp.cmp()`.

The `dircmp` class provides the following methods:

`report()`

Print (to `sys.stdout`) a comparison between *a* and *b*.

`report_partial_closure()`

Print a comparison between *a* and *b* and common immediate subdirectories.

`report_full_closure()`

Print a comparison between *a* and *b* and common subdirectories (recursively).

The `dircmp` class offers a number of interesting attributes that may be used to get various bits of information about the directory trees being compared.

Note that via `__getattr__()` hooks, all attributes are computed lazily, so there is no speed penalty if only those attributes which are lightweight to compute are used.

`left`

The directory *a*.

`right`

The directory *b*.

`left_list`

Files and subdirectories in *a*, filtered by *hide* and *ignore*.

`right_list`

Files and subdirectories in *b*, filtered by *hide* and *ignore*.

`common`

Files and subdirectories in both *a* and *b*.

`left_only`

Files and subdirectories only in *a*.

`right_only`

Files and subdirectories only in *b*.

`common_dirs`

Subdirectories in both *a* and *b*.

`common_files`

Files in both *a* and *b*.

`common_funny`

Names in both *a* and *b*, such that the type differs between the directories, or names for which `os.stat()` reports an error.

`same_files`

Files which are identical in both *a* and *b*, using the class's file comparison operator.

`diff_files`

Files which are in both *a* and *b*, whose contents differ according to the class's file comparison operator.

`funny_files`

Files which are in both *a* and *b*, but could not be compared.

`subdirs`

A dictionary mapping names in `common_dirs` to `dircmp` instances (or `MyDirCmp` instances if this instance is of type `MyDirCmp`, a subclass of `dircmp`).

*Changed in version 3.10:* Previously entries were always `dircmp` instances. Now entries are the same type as *self*, if *self* is a subclass of `dircmp`.

`filecmp.DEFAULT_IGNORES`

*New in version 3.4.*

List of directories ignored by `dircmp` by default.

Here is a simplified example of using the `subdirs` attribute to search recursively through two directories to show common

different files:

```
>>> from filecmp import dircmp
>>> def print_diff_files(dcmp):
...     for name in dcmp.diff_files:
...         print("diff_file %s found in %s and %s" % (name,
...             dcmp.left, dcmp.right))
...     for sub_dcmp in dcmp.subdirs.values():
...         print_diff_files(sub_dcmp)
...
>>> dcmp = dircmp('dir1', 'dir2')
>>> print_diff_files(dcmp)
```

# tempfile — Generate temporary files and directories

**Source code:** [Lib/tempfile.py](https://github.com/python/cpython/tree/3.11/Lib/tempfile.py) [https://github.com/python/cpython/tree/3.11/Lib/tempfile.py]

---

This module creates temporary files and directories. It works on all supported platforms. `TemporaryFile`, `NamedTemporaryFile`, `TemporaryDirectory`, and `SpooledTemporaryFile` are high-level interfaces which provide automatic cleanup and can be used as context managers. `mkstemp()` and `mkdtemp()` are lower-level functions which require manual cleanup.

All the user-callable functions and constructors take additional arguments which allow direct control over the location and name of temporary files and directories. Files names used by this module include a string of random characters which allows those files to be securely created in shared temporary directories. To maintain backward compatibility, the argument order is somewhat odd; it is recommended to use keyword arguments for clarity.

The module defines the following user-callable items:

```
tempfile.TemporaryFile(mode='w+b', buffering=-1,  
encoding=None, newline=None, suffix=None, prefix=None,  
dir=None, *, errors=None)
```

Return a [file-like object](#) that can be used as a temporary storage area. The file is created securely, using the same rules as `mkstemp()`. It will be destroyed as soon as it is closed (including an implicit close when the object is garbage collected). Under Unix, the directory entry for the file is either not created at all or is removed immediately after the file is created. Other platforms do not support this; your code should not rely on a temporary file created using this function

having or not having a visible name in the file system.

The resulting object can be used as a context manager (see [Examples](#)). On completion of the context or destruction of the file object the temporary file will be removed from the filesystem.

The *mode* parameter defaults to `'w+b'` so that the file created can be read and written without being closed. Binary mode is used so that it behaves consistently on all platforms without regard for the data that is stored. *buffering*, *encoding*, *errors* and *newline* are interpreted as for [open\(\)](#).

The *dir*, *prefix* and *suffix* parameters have the same meaning and defaults as with [mkstemp\(\)](#).

The returned object is a true file object on POSIX platforms. On other platforms, it is a file-like object whose **file** attribute is the underlying true file object.

The `os.O_TMPFILE` flag is used if it is available and works (Linux-specific, requires Linux kernel 3.11 or later).

On platforms that are neither Posix nor Cygwin, `TemporaryFile` is an alias for `NamedTemporaryFile`.

Raises an [auditing event](#) `tempfile.mkstemp` with argument `fullpath`.

*Changed in version 3.5:* The `os.O_TMPFILE` flag is now used if available.

*Changed in version 3.8:* Added *errors* parameter.

```
tempfile.NamedTemporaryFile(mode='w+b', buffering=-1,  
encoding=None, newline=None, suffix=None, prefix=None,  
dir=None, delete=True, *, errors=None)
```

This function operates exactly as [TemporaryFile\(\)](#) does, except that the file is guaranteed to have a visible name in the file system (on Unix, the directory entry is not unlinked). That name can be retrieved from the **name** attribute of the

returned file-like object. Whether the name can be used to open the file a second time, while the named temporary file is still open, varies across platforms (it can be so used on Unix; it cannot on Windows). If *delete* is true (the default), the file is deleted as soon as it is closed. The returned object is always a file-like object whose **file** attribute is the underlying true file object. This file-like object can be used in a **with** statement, just like a normal file.

On POSIX (only), a process that is terminated abruptly with SIGKILL cannot automatically delete any NamedTemporaryFiles it created.

Raises an **auditing event** `tempfile.mkstemp` with argument `fullpath`.

*Changed in version 3.8:* Added *errors* parameter.

```
class tempfile.SpooledTemporaryFile(max_size=0, mode='w+b',
buffering=-1, encoding=None, newline=None, suffix=None,
prefix=None, dir=None, *, errors=None)
```

This class operates exactly as **TemporaryFile()** does, except that data is spooled in memory until the file size exceeds *max\_size*, or until the file's **fileno()** method is called, at which point the contents are written to disk and operation proceeds as with **TemporaryFile()**.

The resulting file has one additional method, **rollover()**, which causes the file to roll over to an on-disk file regardless of its size.

The returned object is a file-like object whose **\_file** attribute is either an **io.BytesIO** or **io.TextIOWrapper** object (depending on whether binary or text *mode* was specified) or a true file object, depending on whether **rollover()** has been called. This file-like object can be used in a **with** statement, just like a normal file.

*Changed in version 3.3:* the `truncate` method now accepts a `size` argument.

*Changed in version 3.8:* Added *errors* parameter.

*Changed in version 3.11:* Fully implements the `io.BufferedIOBase` and `io.TextIOBase` abstract base classes (depending on whether binary or text *mode* was specified).

```
class tempfile.TemporaryDirectory(suffix=None, prefix=None,
dir=None, ignore_cleanup_errors=False)
```

This class securely creates a temporary directory using the same rules as `mkdtemp()`. The resulting object can be used as a context manager (see [Examples](#)). On completion of the context or destruction of the temporary directory object, the newly created temporary directory and all its contents are removed from the filesystem.

The directory name can be retrieved from the `name` attribute of the returned object. When the returned object is used as a context manager, the `name` will be assigned to the target of the `as` clause in the `with` statement, if there is one.

The directory can be explicitly cleaned up by calling the `cleanup()` method. If `ignore_cleanup_errors` is true, any unhandled exceptions during explicit or implicit cleanup (such as a `PermissionError` removing open files on Windows) will be ignored, and the remaining removable items deleted on a “best-effort” basis. Otherwise, errors will be raised in whatever context cleanup occurs (the `cleanup()` call, exiting the context manager, when the object is garbage-collected or during interpreter shutdown).

Raises an [auditing event](#) `tempfile.mkdtemp` with argument `fullpath`.

*New in version 3.2.*

*Changed in version 3.10:* Added `ignore_cleanup_errors` parameter.

```
tempfile.mkstemp(suffix=None, prefix=None, dir=None,
```

*text=False*)

Creates a temporary file in the most secure manner possible. There are no race conditions in the file's creation, assuming that the platform properly implements the `os.O_EXCL` flag for `os.open()`. The file is readable and writable only by the creating user ID. If the platform uses permission bits to indicate whether a file is executable, the file is executable by no one. The file descriptor is not inherited by child processes.

Unlike `TemporaryFile()`, the user of `mkstemp()` is responsible for deleting the temporary file when done with it.

If *suffix* is not `None`, the file name will end with that suffix, otherwise there will be no suffix. `mkstemp()` does not put a dot between the file name and the suffix; if you need one, put it at the beginning of *suffix*.

If *prefix* is not `None`, the file name will begin with that prefix; otherwise, a default prefix is used. The default is the return value of `gettempprefix()` or `gettempprefixb()`, as appropriate.

If *dir* is not `None`, the file will be created in that directory; otherwise, a default directory is used. The default directory is chosen from a platform-dependent list, but the user of the application can control the directory location by setting the `TMPDIR`, `TEMP` or `TMP` environment variables. There is thus no guarantee that the generated filename will have any nice properties, such as not requiring quoting when passed to external commands via `os.popen()`.

If any of *suffix*, *prefix*, and *dir* are not `None`, they must be the same type. If they are bytes, the returned name will be bytes instead of str. If you want to force a bytes return value with otherwise default behavior, pass `suffix=b''`.

If *text* is specified and true, the file is opened in text mode. Otherwise, (the default) the file is opened in binary mode.

`mkstemp()` returns a tuple containing an OS-level handle to an open file (as would be returned by `os.open()`) and the

absolute pathname of that file, in that order.

Raises an [auditing event](#) `tempfile.mkstemp` with argument `fullpath`.

*Changed in version 3.5:* `suffix`, `prefix`, and `dir` may now be supplied in bytes in order to obtain a bytes return value. Prior to this, only `str` was allowed. `suffix` and `prefix` now accept and default to `None` to cause an appropriate default value to be used.

*Changed in version 3.6:* The `dir` parameter now accepts a [path-like object](#).

`tempfile.mkdtemp(suffix=None, prefix=None, dir=None)`

Creates a temporary directory in the most secure manner possible. There are no race conditions in the directory's creation. The directory is readable, writable, and searchable only by the creating user ID.

The user of `mkdtemp()` is responsible for deleting the temporary directory and its contents when done with it.

The `prefix`, `suffix`, and `dir` arguments are the same as for `mkstemp()`.

`mkdtemp()` returns the absolute pathname of the new directory if `dir` is `None` or is an absolute path. If `dir` is a relative path, `mkdtemp()` returns a relative path on Python 3.11 and lower. However, on 3.12 it will return an absolute path in all situations.

Raises an [auditing event](#) `tempfile.mkdtemp` with argument `fullpath`.

*Changed in version 3.5:* `suffix`, `prefix`, and `dir` may now be supplied in bytes in order to obtain a bytes return value. Prior to this, only `str` was allowed. `suffix` and `prefix` now accept and default to `None` to cause an appropriate default value to be used.

*Changed in version 3.6:* The *dir* parameter now accepts a [path-like object](#).

`tempfile.gettempdir()`

Return the name of the directory used for temporary files. This defines the default value for the *dir* argument to all functions in this module.

Python searches a standard list of directories to find one which the calling user can create files in. The list is:

1. The directory named by the **TMPDIR** environment variable.
2. The directory named by the **TEMP** environment variable.
3. The directory named by the **TMP** environment variable.
4. A platform-specific location:
  - On Windows, the directories `C:\TEMP`, `C:\TMP`, `\TEMP`, and `\TMP`, in that order.
  - On all other platforms, the directories `/tmp`, `/var/tmp`, and `/usr/tmp`, in that order.
7. As a last resort, the current working directory.

The result of this search is cached, see the description of [tempdir](#) below.

*Changed in version 3.10:* Always returns a str. Previously it would return any [tempdir](#) value regardless of type so long as it was not `None`.

`tempfile.gettempdirb()`

Same as [gettempdir\(\)](#) but the return value is in bytes.

*New in version 3.5.*

`tempfile.gettempprefix()`

Return the filename prefix used to create temporary files. This does not contain the directory component.

`tempfile.gettempprefixb()`

Same as `gettempprefix()` but the return value is in bytes.

*New in version 3.5.*

The module uses a global variable to store the name of the directory used for temporary files returned by `gettempdir()`. It can be set directly to override the selection process, but this is discouraged. All functions in this module take a *dir* argument which can be used to specify the directory. This is the recommended approach that does not surprise other unsuspecting code by changing global API behavior.

`tempfile.tempdir`

When set to a value other than `None`, this variable defines the default value for the *dir* argument to the functions defined in this module, including its type, bytes or str. It cannot be a [path-like object](#).

If `tempdir` is `None` (the default) at any call to any of the above functions except `gettempprefix()` it is initialized following the algorithm described in `gettempdir()`.

### Note

Beware that if you set `tempdir` to a bytes value, there is a nasty side effect: The global default return type of `mkstemp()` and `mkdtemp()` changes to bytes when no explicit `prefix`, `suffix`, or `dir` arguments of type str are supplied. Please do not write code expecting or depending on this. This awkward behavior is maintained for compatibility with the historical implementation.

## Examples

Here are some examples of typical usage of the `tempfile` module:

```
>>> import tempfile
```

```
# create a temporary file and write some data to it
>>> fp = tempfile.TemporaryFile()
>>> fp.write(b'Hello world!')
# read data from file
>>> fp.seek(0)
>>> fp.read()
b'Hello world!'
# close the file, it will be removed
>>> fp.close()
```

```
# create a temporary file using a context manager
>>> with tempfile.TemporaryFile() as fp:
...     fp.write(b'Hello world!')
...     fp.seek(0)
...     fp.read()
b'Hello world!'
>>>
# file is now closed and removed
```

```
# create a temporary directory using the context manager
>>> with tempfile.TemporaryDirectory() as tmpdirname:
...     print('created temporary directory', tmpdirname)
>>>
# directory and contents have been removed
```

## Deprecated functions and variables

A historical way to create temporary files was to first generate a file name with the `mktemp()` function and then create a file using this name. Unfortunately this is not secure, because a different process may create a file with this name in the time between the call to `mktemp()` and the subsequent attempt to create the file by the first process. The solution is to combine the two steps and create the file immediately. This approach is used by `mkstemp()` and the other functions described above.

```
tempfile.mktemp(suffix="", prefix='tmp', dir=None)
```

*Deprecated since version 2.3:* Use `mkstemp()` instead.

Return an absolute pathname of a file that did not exist at the time the call is made. The *prefix*, *suffix*, and *dir* arguments are similar to those of `mkstemp()`, except that bytes file names, `suffix=None` and `prefix=None` are not supported.

### Warning

Use of this function may introduce a security hole in your program. By the time you get around to doing anything with the file name it returns, someone else may have beaten you to the punch. `mktemp()` usage can be replaced easily with `NamedTemporaryFile()`, passing it the `delete=False` parameter:

```
>>> f = NamedTemporaryFile(delete=False)
>>> f.name
'/tmp/tmpjtjujt'
>>> f.write(b"Hello World!\n")
13
>>> f.close()
>>> os.unlink(f.name)
>>> os.path.exists(f.name)
False
```

# glob — Unix style pathname pattern expansion

**Source code:** [Lib/glob.py](https://github.com/python/cpython/tree/3.11/Lib/glob.py) [https://github.com/python/cpython/tree/3.11/Lib/glob.py]

---

The `glob` module finds all the pathnames matching a specified pattern according to the rules used by the Unix shell, although results are returned in arbitrary order. No tilde expansion is done, but `*`, `?`, and character ranges expressed with `[]` will be correctly matched. This is done by using the `os.scandir()` and `fnmatch.fnmatch()` functions in concert, and not by actually invoking a subshell.

Note that files beginning with a dot (.) can only be matched by patterns that also start with a dot, unlike `fnmatch.fnmatch()` or `pathlib.Path.glob()`. (For tilde and shell variable expansion, use `os.path.expanduser()` and `os.path.expandvars()`.)

For a literal match, wrap the meta-characters in brackets. For example, `'[?]'` matches the character `'?'`.

## See also

The `pathlib` module offers high-level path objects.

`glob.glob(pathname, *, root_dir=None, dir_fd=None, recursive=False, include_hidden=False)`

Return a possibly empty list of path names that match *pathname*, which must be a string containing a path specification. *pathname* can be either absolute (like `/usr/src/Python-1.5/Makefile`) or relative (like `../../Tools/*/*.gif`), and can contain shell-style wildcards.

Broken symlinks are included in the results (as in the shell). Whether or not the results are sorted depends on the file system. If a file that satisfies conditions is removed or added during the call of this function, whether a path name for that file be included is unspecified.

If *root\_dir* is not `None`, it should be a [path-like object](#) specifying the root directory for searching. It has the same effect on [glob\(\)](#) as changing the current directory before calling it. If *pathname* is relative, the result will contain paths relative to *root\_dir*.

This function can support [paths relative to directory descriptors](#) with the *dir\_fd* parameter.

If *recursive* is true, the pattern “\*\*” will match any files and zero or more directories, subdirectories and symbolic links to directories. If the pattern is followed by an [os.sep](#) or [os.altsep](#) then files will not match.

If *include\_hidden* is true, “\*\*” pattern will match hidden directories.

Raises an [auditing event](#) `glob.glob` with arguments *pathname*, *recursive*.

Raises an [auditing event](#) `glob.glob/2` with arguments *pathname*, *recursive*, *root\_dir*, *dir\_fd*.

## Note

Using the “\*\*” pattern in large directory trees may consume an inordinate amount of time.

*Changed in version 3.5:* Support for recursive globs using “\*\*”.

*Changed in version 3.10:* Added the *root\_dir* and *dir\_fd* parameters.

*Changed in version 3.11:* Added the *include\_hidden* parameter.

`glob.glob(pathname, *, root_dir=None, dir_fd=None, recursive=False, include_hidden=False)`

Return an [iterator](#) which yields the same values as `glob()` without actually storing them all simultaneously.

Raises an [auditing event](#) `glob.glob` with arguments `pathname`, `recursive`.

Raises an [auditing event](#) `glob.glob/2` with arguments `pathname`, `recursive`, `root_dir`, `dir_fd`.

*Changed in version 3.5:* Support for recursive globs using `“**”`.

*Changed in version 3.10:* Added the `root_dir` and `dir_fd` parameters.

*Changed in version 3.11:* Added the `include_hidden` parameter.

`glob.escape(pathname)`

Escape all special characters (`'?'`, `'*'` and `'['`). This is useful if you want to match an arbitrary literal string that may have special characters in it. Special characters in drive/UNC sharepoints are not escaped, e.g. on Windows `escape('///?/c:/Quo vadis?.txt')` returns `'///?/c:/Quo vadis[?].txt'`.

*New in version 3.4.*

For example, consider a directory containing the following files: `1.gif`, `2.txt`, `card.gif` and a subdirectory `sub` which contains only the file `3.txt`. `glob()` will produce the following results. Notice how any leading components of the path are preserved.

```
>>> import glob
>>> glob.glob('./[0-9].*')
['./1.gif', './2.txt']
>>> glob.glob('*.gif')
['1.gif', 'card.gif']
>>> glob.glob('?.gif')
```

```
['1.gif']
>>> glob.glob('**/*.txt', recursive=True)
['2.txt', 'sub/3.txt']
>>> glob.glob('./**/', recursive=True)
['./', './sub/']
```

If the directory contains files starting with `.` they won't be matched by default. For example, consider a directory containing `card.gif` and `.card.gif`:

```
>>> import glob
>>> glob.glob('*.gif')
['card.gif']
>>> glob.glob('.*')
['.card.gif']
```

### Module [fnmatch](#)

Shell-style filename (not path) expansion

# fnmatch — Unix filename pattern matching

**Source code:** [Lib/fnmatch.py](https://github.com/python/cpython/tree/3.11/Lib/fnmatch.py) [https://github.com/python/cpython/tree/3.11/Lib/fnmatch.py]

---

This module provides support for Unix shell-style wildcards, which are *not* the same as regular expressions (which are documented in the [re](#) module). The special characters used in shell-style wildcards are:

## **Matching**

---

**`*`** matches everything

---

**`?`** matches any single character

---

**`%seq`** matches any character in *seq*

---

**`%!seq`** matches any character not in *seq*

---

For a literal match, wrap the meta-characters in brackets. For example, `'[?]'` matches the character `'?'`.

Note that the filename separator (`'/'` on Unix) is *not* special to this module. See module [glob](#) for pathname expansion ([glob](#) uses [filter\(\)](#) to match pathname segments). Similarly, filenames starting with a period are not special for this module, and are matched by the `*` and `?` patterns.

Also note that [functools.lru\\_cache\(\)](#) with the *maxsize* of 32768 is used to cache the compiled regex patterns in the following functions: [fnmatch\(\)](#), [fnmatchcase\(\)](#), [filter\(\)](#).

`fnmatch.fnmatch(filename, pattern)`

Test whether the *filename* string matches the *pattern* string, returning **True** or **False**. Both parameters are case-normalized using [os.path.normcase\(\)](#).

[fnmatchcase\(\)](#) can be used to perform a case-sensitive

comparison, regardless of whether that's standard for the operating system.

This example will print all file names in the current directory with the extension `.txt`:

```
import fnmatch
import os

for file in os.listdir('.'):
    if fnmatch.fnmatch(file, '*.txt'):
        print(file)
```

`fnmatch.fnmatchcase(filename, pattern)`

Test whether *filename* matches *pattern*, returning **True** or **False**; the comparison is case-sensitive and does not apply **`os.path.normcase()`**.

`fnmatch.filter(names, pattern)`

Construct a list from those elements of the iterable *names* that match *pattern*. It is the same as `[n for n in names if fnmatch(n, pattern)]`, but implemented more efficiently.

`fnmatch.translate(pattern)`

Return the shell-style *pattern* converted to a regular expression for using with **`re.match()`**.

Example:

```
>>> import fnmatch, re
>>>
>>> regex = fnmatch.translate('*.txt')
>>> regex
'(?s:.*\\.txt)\\Z'
>>> reobj = re.compile(regex)
>>> reobj.match('foobar.txt')
<re.Match object; span=(0, 10), match='foobar.txt'>
```

**See also**

**Module** [glob](#)

Unix shell-style path expansion.

# linecache — Random access to text lines

**Source code:** [Lib/linecache.py](https://github.com/python/cpython/tree/3.11/Lib/linecache.py) [https://github.com/python/cpython/tree/3.11/Lib/linecache.py]

---

The `linecache` module allows one to get any line from a Python source file, while attempting to optimize internally, using a cache, the common case where many lines are read from a single file. This is used by the `traceback` module to retrieve source lines for inclusion in the formatted traceback.

The `tokenize.open()` function is used to open files. This function uses `tokenize.detect_encoding()` to get the encoding of the file; in the absence of an encoding token, the file encoding defaults to UTF-8.

The `linecache` module defines the following functions:

`linecache.getline(filename, lineno, module_globals = None)`

Get line *lineno* from file named *filename*. This function will never raise an exception — it will return `' '` on errors (the terminating newline character will be included for lines that are found).

If a file named *filename* is not found, the function first checks for a [PEP 302](https://peps.python.org/pep-0302/) [https://peps.python.org/pep-0302/] `__loader__` in *module\_globals*. If there is such a loader and it defines a `get_source` method, then that determines the source lines (if `get_source()` returns `None`, then `' '` is returned). Finally, if *filename* is a relative filename, it is looked up relative to the entries in the module search path, `sys.path`.

`linecache.clearcache()`

Clear the cache. Use this function if you no longer need lines from files previously read using `getline()`.

`linecache.checkcache(filename=None)`

Check the cache for validity. Use this function if files in the cache may have changed on disk, and you require the updated version. If *filename* is omitted, it will check all the entries in the cache.

`linecache.lazycache(filename, module_globals)`

Capture enough detail about a non-file-based module to permit getting its lines later via `getline()` even if *module\_globals* is `None` in the later call. This avoids doing I/O until a line is actually needed, without having to carry the module globals around indefinitely.

*New in version 3.5.*

Example:

```
>>> import linecache
>>> linecache.getline(linecache.__file__, 8)
'import sys\n'
```

# shutil — High-level file operations

**Source code:** [Lib/shutil.py](https://github.com/python/cpython/tree/3.11/Lib/shutil.py) [https://github.com/python/cpython/tree/3.11/Lib/shutil.py]

---

The `shutil` module offers a number of high-level operations on files and collections of files. In particular, functions are provided which support file copying and removal. For operations on individual files, see also the `os` module.

## Warning

Even the higher-level file copying functions (`shutil.copy()`, `shutil.copy2()`) cannot copy all file metadata.

On POSIX platforms, this means that file owner and group are lost as well as ACLs. On Mac OS, the resource fork and other metadata are not used. This means that resources will be lost and file type and creator codes will not be correct. On Windows, file owners, ACLs and alternate data streams are not copied.

## Directory and files operations

`shutil.copyfileobj(fsrc, fdst[, length])`

Copy the contents of the file-like object *fsrc* to the file-like object *fdst*. The integer *length*, if given, is the buffer size. In particular, a negative *length* value means to copy the data without looping over the source data in chunks; by default the data is read in chunks to avoid uncontrolled memory consumption. Note that if the current file position of the *fsrc* object is not 0, only the contents from the current file position to the end of the file will be copied.

`shutil.copyfile(src, dst, *, follow_symlinks=True)`

Copy the contents (no metadata) of the file named *src* to a file named *dst* and return *dst* in the most efficient way possible. *src* and *dst* are path-like objects or path names given as strings.

*dst* must be the complete target file name; look at `copy()` for a copy that accepts a target directory path. If *src* and *dst* specify the same file, `SameFileError` is raised.

The destination location must be writable; otherwise, an `OSError` exception will be raised. If *dst* already exists, it will be replaced. Special files such as character or block devices and pipes cannot be copied with this function.

If *follow\_symlinks* is false and *src* is a symbolic link, a new symbolic link will be created instead of copying the file *src* points to.

Raises an `auditing event` `shutil.copyfile` with arguments *src*, *dst*.

*Changed in version 3.3:* `IOError` used to be raised instead of `OSError`. Added *follow\_symlinks* argument. Now returns *dst*.

*Changed in version 3.4:* Raise `SameFileError` instead of `Error`. Since the former is a subclass of the latter, this change is backward compatible.

*Changed in version 3.8:* Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See [Platform-dependent efficient copy operations](#) section.

*exception* `shutil.SameFileError`

This exception is raised if source and destination in `copyfile()` are the same file.

*New in version 3.4.*

`shutil.copymode(src, dst, *, follow_symlinks=True)`

Copy the permission bits from *src* to *dst*. The file contents, owner, and group are unaffected. *src* and *dst* are path-like objects or path names given as strings. If *follow\_symlinks* is false, and both *src* and *dst* are symbolic links, `copymode()` will attempt to modify the mode of *dst* itself (rather than the file it points to). This functionality is not available on every platform; please see `copystat()` for more information. If `copymode()` cannot modify symbolic links on the local platform, and it is asked to do so, it will do nothing and return.

Raises an [auditing event](#) `shutil.copymode` with arguments *src*, *dst*.

*Changed in version 3.3:* Added *follow\_symlinks* argument.

`shutil.copystat(src, dst, *, follow_symlinks=True)`

Copy the permission bits, last access time, last modification time, and flags from *src* to *dst*. On Linux, `copystat()` also copies the “extended attributes” where possible. The file contents, owner, and group are unaffected. *src* and *dst* are path-like objects or path names given as strings.

If *follow\_symlinks* is false, and *src* and *dst* both refer to symbolic links, `copystat()` will operate on the symbolic links themselves rather than the files the symbolic links refer to—reading the information from the *src* symbolic link, and writing the information to the *dst* symbolic link.

### Note

Not all platforms provide the ability to examine and modify symbolic links. Python itself can tell you what functionality is locally available.

- If `os.chmod` in `os.supports_follow_symlinks` is `True`, `copystat()` can modify the permission bits of a symbolic link.

- If `os.utime` in `os.supports_follow_symlinks` is `True`, `copystat()` can modify the last access and modification times of a symbolic link.
- If `os.chflags` in `os.supports_follow_symlinks` is `True`, `copystat()` can modify the flags of a symbolic link. (`os.chflags` is not available on all platforms.)

On platforms where some or all of this functionality is unavailable, when asked to modify a symbolic link, `copystat()` will copy everything it can. `copystat()` never returns failure.

Please see `os.supports_follow_symlinks` for more information.

Raises an `auditing event` `shutil.copystat` with arguments `src`, `dst`.

*Changed in version 3.3:* Added `follow_symlinks` argument and support for Linux extended attributes.

`shutil.copy(src, dst, *, follow_symlinks=True)`

Copies the file `src` to the file or directory `dst`. `src` and `dst` should be `path-like objects` or strings. If `dst` specifies a directory, the file will be copied into `dst` using the base filename from `src`. If `dst` specifies a file that already exists, it will be replaced. Returns the path to the newly created file.

If `follow_symlinks` is `false`, and `src` is a symbolic link, `dst` will be created as a symbolic link. If `follow_symlinks` is `true` and `src` is a symbolic link, `dst` will be a copy of the file `src` refers to.

`copy()` copies the file data and the file's permission mode (see `os.chmod()`). Other metadata, like the file's creation and modification times, is not preserved. To preserve all file metadata from the original, use `copy2()` instead.

Raises an [auditing event](#) `shutil.copyfile` with arguments `src`, `dst`.

Raises an [auditing event](#) `shutil.copymode` with arguments `src`, `dst`.

*Changed in version 3.3:* Added `follow_symlinks` argument. Now returns path to the newly created file.

*Changed in version 3.8:* Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See [Platform-dependent efficient copy operations](#) section.

`shutil.copy2(src, dst, *, follow_symlinks=True)`

Identical to [copy\(\)](#) except that [copy2\(\)](#) also attempts to preserve file metadata.

When `follow_symlinks` is false, and `src` is a symbolic link, [copy2\(\)](#) attempts to copy all metadata from the `src` symbolic link to the newly created `dst` symbolic link. However, this functionality is not available on all platforms. On platforms where some or all of this functionality is unavailable, [copy2\(\)](#) will preserve all the metadata it can; [copy2\(\)](#) never raises an exception because it cannot preserve file metadata.

[copy2\(\)](#) uses [copystat\(\)](#) to copy the file metadata. Please see [copystat\(\)](#) for more information about platform support for modifying symbolic link metadata.

Raises an [auditing event](#) `shutil.copyfile` with arguments `src`, `dst`.

Raises an [auditing event](#) `shutil.copystat` with arguments `src`, `dst`.

*Changed in version 3.3:* Added `follow_symlinks` argument, try to copy extended file system attributes too (currently Linux only). Now returns path to the newly created file.

*Changed in version 3.8:* Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See [Platform-dependent efficient copy operations](#) section.

`shutil.ignore_patterns(*patterns)`

This factory function creates a function that can be used as a callable for `copytree()`'s *ignore* argument, ignoring files and directories that match one of the glob-style *patterns* provided. See the example below.

`shutil.copytree(src, dst, symlinks=False, ignore=None,  
copy_function=copy2, ignore_dangling_symlinks=False,  
dirs_exist_ok=False)`

Recursively copy an entire directory tree rooted at *src* to a directory named *dst* and return the destination directory. All intermediate directories needed to contain *dst* will also be created by default.

Permissions and times of directories are copied with `copystat()`, individual files are copied using `copy2()`.

If *symlinks* is true, symbolic links in the source tree are represented as symbolic links in the new tree and the metadata of the original links will be copied as far as the platform allows; if false or omitted, the contents and metadata of the linked files are copied to the new tree.

When *symlinks* is false, if the file pointed by the symlink doesn't exist, an exception will be added in the list of errors raised in an `Error` exception at the end of the copy process. You can set the optional *ignore\_dangling\_symlinks* flag to true if you want to silence this exception. Notice that this option has no effect on platforms that don't support `os.symlink()`.

If *ignore* is given, it must be a callable that will receive as its arguments the directory being visited by `copytree()`, and a list of its contents, as returned by `os.listdir()`. Since `copytree()` is called recursively, the *ignore* callable will be

called once for each directory that is copied. The callable must return a sequence of directory and file names relative to the current directory (i.e. a subset of the items in its second argument); these names will then be ignored in the copy process. `ignore_patterns()` can be used to create such a callable that ignores names based on glob-style patterns.

If exception(s) occur, an **Error** is raised with a list of reasons.

If *copy\_function* is given, it must be a callable that will be used to copy each file. It will be called with the source path and the destination path as arguments. By default, `copy2()` is used, but any function that supports the same signature (like `copy()`) can be used.

If *dirs\_exist\_ok* is false (the default) and *dst* already exists, a **FileExistsError** is raised. If *dirs\_exist\_ok* is true, the copying operation will continue if it encounters existing directories, and files within the *dst* tree will be overwritten by corresponding files from the *src* tree.

Raises an **auditing event** `shutil.copypath` with arguments *src*, *dst*.

*Changed in version 3.3:* Copy metadata when *symlinks* is false. Now returns *dst*.

*Changed in version 3.2:* Added the *copy\_function* argument to be able to provide a custom copy function. Added the *ignore\_dangling\_symlinks* argument to silence dangling symlinks errors when *symlinks* is false.

*Changed in version 3.8:* Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See **Platform-dependent efficient copy operations** section.

*New in version 3.8:* The *dirs\_exist\_ok* parameter.

```
shutil.rmtree(path, ignore_errors=False, onerror=None, *,
```

*dir\_fd = None*)

Delete an entire directory tree; *path* must point to a directory (but not a symbolic link to a directory). If *ignore\_errors* is true, errors resulting from failed removals will be ignored; if false or omitted, such errors are handled by calling a handler specified by *onerror* or, if that is omitted, they raise an exception.

This function can support [paths relative to directory descriptors](#).

### Note

On platforms that support the necessary fd-based functions a symlink attack resistant version of `rmtree()` is used by default. On other platforms, the `rmtree()` implementation is susceptible to a symlink attack: given proper timing and circumstances, attackers can manipulate symlinks on the filesystem to delete files they wouldn't be able to access otherwise. Applications can use the `rmtree.avoids_symlink_attacks` function attribute to determine which case applies.

If *onerror* is provided, it must be a callable that accepts three parameters: *function*, *path*, and *excinfo*.

The first parameter, *function*, is the function which raised the exception; it depends on the platform and implementation. The second parameter, *path*, will be the path name passed to *function*. The third parameter, *excinfo*, will be the exception information returned by `sys.exc_info()`. Exceptions raised by *onerror* will not be caught.

Raises an [auditing event](#) `shutil.rmtree` with arguments *path*, *dir\_fd*.

*Changed in version 3.3:* Added a symlink attack resistant version that is used automatically if platform supports fd-based functions.

*Changed in version 3.8:* On Windows, will no longer delete the contents of a directory junction before removing the junction.

*Changed in version 3.11:* The `dir_fd` parameter.

`rmtree.avoids_symlink_attacks`

Indicates whether the current platform and implementation provides a symlink attack resistant version of `rmtree()`. Currently this is only true for platforms supporting fd-based directory access functions.

*New in version 3.3.*

`shutil.move(src, dst, copy_function=copy2)`

Recursively move a file or directory (`src`) to another location (`dst`) and return the destination.

If the destination is an existing directory, then `src` is moved inside that directory. If the destination already exists but is not a directory, it may be overwritten depending on `os.rename()` semantics.

If the destination is on the current filesystem, then `os.rename()` is used. Otherwise, `src` is copied to `dst` using `copy_function` and then removed. In case of symlinks, a new symlink pointing to the target of `src` will be created in or as `dst` and `src` will be removed.

If `copy_function` is given, it must be a callable that takes two arguments `src` and `dst`, and will be used to copy `src` to `dst` if `os.rename()` cannot be used. If the source is a directory, `copytree()` is called, passing it the `copy_function()`. The default `copy_function` is `copy2()`. Using `copy()` as the `copy_function` allows the move to succeed when it is not possible to also copy the metadata, at the expense of not copying any of the metadata.

Raises an `auditing event` `shutil.move` with arguments `src`, `dst`.

*Changed in version 3.3:* Added explicit symlink handling for foreign filesystems, thus adapting it to the behavior of GNU's **mv**. Now returns *dst*.

*Changed in version 3.5:* Added the *copy\_function* keyword argument.

*Changed in version 3.8:* Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See [Platform-dependent efficient copy operations](#) section.

*Changed in version 3.9:* Accepts a [path-like object](#) for both *src* and *dst*.

`shutil.disk_usage(path)`

Return disk usage statistics about the given path as a [named tuple](#) with the attributes *total*, *used* and *free*, which are the amount of total, used and free space, in bytes. *path* may be a file or a directory.

*New in version 3.3.*

*Changed in version 3.8:* On Windows, *path* can now be a file or directory.

[Availability](#): Unix, Windows.

`shutil.chown(path, user=None, group=None)`

Change owner *user* and/or *group* of the given *path*.

*user* can be a system user name or a uid; the same applies to *group*. At least one argument is required.

See also [os.chown\(\)](#), the underlying function.

Raises an [auditing event](#) `shutil.chown` with arguments *path*, *user*, *group*.

[Availability](#): Unix.

*New in version 3.3.*

`shutil.which(cmd, mode=os.F_OK | os.X_OK, path=None)`

Return the path to an executable which would be run if the given *cmd* was called. If no *cmd* would be called, return `None`.

*mode* is a permission mask passed to `os.access()`, by default determining if the file exists and executable.

When no *path* is specified, the results of `os.environ()` are used, returning either the “PATH” value or a fallback of `os.defpath`.

On Windows, the current directory is always prepended to the *path* whether or not you use the default or provide your own, which is the behavior the command shell uses when finding executables. Additionally, when finding the *cmd* in the *path*, the `PATHEXT` environment variable is checked. For example, if you call `shutil.which("python")`, `which()` will search `PATHEXT` to know that it should look for `python.exe` within the *path* directories. For example, on Windows:

```
>>> shutil.which("python")
'C:\\Python33\\python.EXE'
```

*New in version 3.3.*

*Changed in version 3.8:* The `bytes` type is now accepted. If *cmd* type is `bytes`, the result type is also `bytes`.

*exception* `shutil.Error`

This exception collects exceptions that are raised during a multi-file operation. For `copytree()`, the exception argument is a list of 3-tuples (*srcname*, *dstname*, *exception*).

## Platform-dependent efficient copy operations

Starting from Python 3.8, all functions involving a file copy

(`copyfile()`, `copy()`, `copy2()`, `copytree()`, and `move()`) may use platform-specific “fast-copy” syscalls in order to copy the file more efficiently (see [bpo-33671](https://bugs.python.org/issue?@action=redirect&bpo=33671) [https://bugs.python.org/issue?@action=redirect&bpo=33671]). “fast-copy” means that the copying operation occurs within the kernel, avoiding the use of userspace buffers in Python as in “`outfd.write(infd.read())`”.

On macOS [fcopyfile](http://www.manpagez.com/man/3/copyfile/) [http://www.manpagez.com/man/3/copyfile/] is used to copy the file content (not metadata).

On Linux `os.sendfile()` is used.

On Windows `shutil.copyfile()` uses a bigger default buffer size (1 MiB instead of 64 KiB) and a `memoryview()`-based variant of `shutil.copyfileobj()` is used.

If the fast-copy operation fails and no data was written in the destination file then `shutil` will silently fallback on using less efficient `copyfileobj()` function internally.

*Changed in version 3.8.*

## copytree example

An example that uses the `ignore_patterns()` helper:

```
from shutil import copytree, ignore_patterns

copytree(source, destination, ignore=ignore_patterns('*.
```

This will copy everything except `.pyc` files and files or directories whose name starts with `tmp`.

Another example that uses the `ignore` argument to add a logging call:

```
from shutil import copytree
import logging

def _logpath(path, names):
    logging.info('Working in %s', path)
```

```
        return []    # nothing will be ignored

copytree(source, destination, ignore=_logpath)
```

## rmtree example

This example shows how to remove a directory tree on Windows where some of the files have their read-only bit set. It uses the `onerror` callback to clear the readonly bit and reattempt the remove. Any subsequent failure will propagate.

```
import os, stat
import shutil

def remove_readonly(func, path, _):
    "Clear the readonly bit and reattempt the removal"
    os.chmod(path, stat.S_IWRITE)
    func(path)

shutil.rmtree(directory, onerror=remove_readonly)
```

## Archiving operations

*New in version 3.2.*

*Changed in version 3.5:* Added support for the *xz*tar format.

High-level utilities to create and read compressed and archived files are also provided. They rely on the [zipfile](#) and [tarfile](#) modules.

```
shutil.make_archive(base_name, format[, root_dir[, base_dir[,
verbose[, dry_run[, owner[, group[, logger]]]]]]])
```

Create an archive file (such as zip or tar) and return its name.

*base\_name* is the name of the file to create, including the path, minus any format-specific extension. *format* is the archive format: one of “zip” (if the [zlib](#) module is available), “tar”, “gztar” (if the [zlib](#) module is available), “bztar” (if the [bz2](#)

module is available), or “xztar” (if the [lzma](#) module is available).

*root\_dir* is a directory that will be the root directory of the archive, all paths in the archive will be relative to it; for example, we typically `chdir` into *root\_dir* before creating the archive.

*base\_dir* is the directory where we start archiving from; i.e. *base\_dir* will be the common prefix of all files and directories in the archive. *base\_dir* must be given relative to *root\_dir*. See [Archiving example with base\\_dir](#) for how to use *base\_dir* and *root\_dir* together.

*root\_dir* and *base\_dir* both default to the current directory.

If *dry\_run* is true, no archive is created, but the operations that would be executed are logged to *logger*.

*owner* and *group* are used when creating a tar archive. By default, uses the current owner and group.

*logger* must be an object compatible with [PEP 282](#) [<https://peps.python.org/pep-0282/>], usually an instance of [logging.Logger](#).

The *verbose* argument is unused and deprecated.

Raises an [auditing event](#) `shutil.make_archive` with arguments `base_name`, `format`, `root_dir`, `base_dir`.

## Note

This function is not thread-safe when custom archivers registered with [register\\_archive\\_format\(\)](#) are used. In this case it temporarily changes the current working directory of the process to perform archiving.

*Changed in version 3.8:* The modern pax (POSIX.1-2001) format is now used instead of the legacy GNU format for archives created with `format="tar"`.

*Changed in version 3.10.6:* This function is now made thread-safe during creation of standard `.zip` and `tar` archives.

`shutil.get_archive_formats()`

Return a list of supported formats for archiving. Each element of the returned sequence is a tuple `(name, description)`.

By default `shutil` provides these formats:

- *zip*: ZIP file (if the `zlib` module is available).
- *tar*: Uncompressed tar file. Uses POSIX.1-2001 pax format for new archives.
- *gztar*: gzip'ed tar-file (if the `zlib` module is available).
- *bztar*: bzip2'ed tar-file (if the `bz2` module is available).
- *xztar*: xz'ed tar-file (if the `lzma` module is available).

You can register new formats or provide your own archiver for any existing formats, by using

`register_archive_format()`.

`shutil.register_archive_format(name, function[, extra_args[, description]])`

Register an archiver for the format *name*.

*function* is the callable that will be used to unpack archives. The callable will receive the *base\_name* of the file to create, followed by the *base\_dir* (which defaults to `os.curdir`) to start archiving from. Further arguments are passed as keyword arguments: *owner*, *group*, *dry\_run* and *logger* (as passed in `make_archive()`).

If given, *extra\_args* is a sequence of `(name, value)` pairs that will be used as extra keywords arguments when the archiver callable is used.

*description* is used by `get_archive_formats()` which returns the list of archivers. Defaults to an empty string.

`shutil.unregister_archive_format(name)`

Remove the archive format *name* from the list of supported formats.

```
shutil.unpack_archive(filename[, extract_dir[, format[, filter]]])
```

Unpack an archive. *filename* is the full path of the archive.

*extract\_dir* is the name of the target directory where the archive is unpacked. If not provided, the current working directory is used.

*format* is the archive format: one of “zip”, “tar”, “gztar”, “bztar”, or “xztar”. Or any other format registered with [register\\_unpack\\_format\(\)](#). If not provided, [unpack\\_archive\(\)](#) will use the archive file name extension and see if an unpacker was registered for that extension. In case none is found, a [ValueError](#) is raised.

The keyword-only *filter* argument, which was added in Python 3.11.4, is passed to the underlying unpacking function. For zip files, *filter* is not accepted. For tar files, it is recommended to set it to `'data'`, unless using features specific to tar and UNIX-like filesystems. (See [Extraction filters](#) for details.) The `'data'` filter will become the default for tar files in Python 3.14.

Raises an [auditing event](#) `shutil.unpack_archive` with arguments `filename`, `extract_dir`, `format`.

## Warning

Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of the path specified in the *extract\_dir* argument, e.g. members that have absolute filenames starting with “/” or filenames with two dots “..”.

*Changed in version 3.7:* Accepts a [path-like object](#) for *filename* and *extract\_dir*.

*Changed in version 3.11.4:* Added the *filter* argument.

```
shutil.register_unpack_format(name, extensions, function[,  
extra_args[, description]])
```

Registers an unpack format. *name* is the name of the format and *extensions* is a list of extensions corresponding to the format, like `.zip` for Zip files.

*function* is the callable that will be used to unpack archives. The callable will receive:

- the path of the archive, as a positional argument;
- the directory the archive must be extracted to, as a positional argument;
- possibly a *filter* keyword argument, if it was given to `unpack_archive()`;
- additional keyword arguments, specified by *extra\_args* as a sequence of (name, value) tuples.

*description* can be provided to describe the format, and will be returned by the `get_unpack_formats()` function.

```
shutil.unregister_unpack_format(name)
```

Unregister an unpack format. *name* is the name of the format.

```
shutil.get_unpack_formats()
```

Return a list of all registered formats for unpacking. Each element of the returned sequence is a tuple (name, extensions, description).

By default `shutil` provides these formats:

- *zip*: ZIP file (unpacking compressed files works only if the corresponding module is available).
- *tar*: uncompressed tar file.
- *gztar*: gzip'ed tar-file (if the `zlib` module is available).
- *bztar*: bzip2'ed tar-file (if the `bz2` module is available).
- *xztar*: xz'ed tar-file (if the `lzma` module is available).

You can register new formats or provide your own unpacker for any existing formats, by using

```
register_unpack_format().
```

## Archiving example

In this example, we create a gzip'ed tar-file archive containing all files found in the `.ssh` directory of the user:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~',
>>> root_dir = os.path.expanduser(os.path.join('~', '.ssh'))
>>> make_archive(archive_name, 'gztar', root_dir)
'/Users/tarek/myarchive.tar.gz'
```

The resulting archive contains:

```
$ tar -tzvf /Users/tarek/myarchive.tar.gz
drwx----- tarek/staff      0 2010-02-01 16:23:40 ./
-rw-r--r-- tarek/staff    609 2008-06-09 13:26:54 ./aut
-rwxr-xr-x tarek/staff     65 2008-06-09 13:26:54 ./con
-rwx----- tarek/staff    668 2008-06-09 13:26:54 ./id_
-rwxr-xr-x tarek/staff    609 2008-06-09 13:26:54 ./id_
-rw----- tarek/staff   1675 2008-06-09 13:26:54 ./id_
-rw-r--r-- tarek/staff    397 2008-06-09 13:26:54 ./id_
-rw-r--r-- tarek/staff  37192 2010-02-06 18:23:10 ./kno
```

## Archiving example with *base\_dir*

In this example, similar to the [one above](#), we show how to use `make_archive()`, but this time with the usage of *base\_dir*. We now have the following directory structure:

```
$ tree tmp
tmp
  root
    structure
      content
        please_add.txt
        do_not_add.txt
```

In the final archive, `please_add.txt` should be included, but `do_not_add.txt` should not. Therefore we use the following:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~',
>>> make_archive(
...     archive_name,
...     'tar',
...     root_dir='tmp/root',
...     base_dir='structure/content',
... )
'/Users/tarek/my_archive.tar'
```

Listing the files in the resulting archive gives us:

```
$ python -m tarfile -l /Users/tarek/myarchive.tar
structure/content/
structure/content/please_add.txt
```

## Querying the size of the output terminal

`shutil.get_terminal_size(fallback=(columns, lines))`

Get the size of the terminal window.

For each of the two dimensions, the environment variable, `COLUMNS` and `LINES` respectively, is checked. If the variable is defined and the value is a positive integer, it is used.

When `COLUMNS` or `LINES` is not defined, which is the common case, the terminal connected to `sys.__stdout__` is queried by invoking `os.get_terminal_size()`.

If the terminal size cannot be successfully queried, either because the system doesn't support querying, or because we are not connected to a terminal, the value given in `fallback` parameter is used. `fallback` defaults to `(80, 24)` which is the default size used by many terminal emulators.

The value returned is a named tuple of type `os.terminal_size`.

See also: The Single UNIX Specification, Version 2, [Other Environment Variables](https://pubs.opengroup.org/onlinepubs/7908799/xbd/envvar.html#tag_002_003) [https://pubs.opengroup.org/onlinepubs/7908799/xbd/envvar.html#tag\_002\_003].

*New in version 3.3.*

*Changed in version 3.11:* The `fallback` values are also used if `os.get_terminal_size()` returns zeroes.

# Data Persistence

The modules described in this chapter support storing Python data in a persistent form on disk. The `pickle` and `marshal` modules can turn many Python data types into a stream of bytes and then recreate the objects from the bytes. The various DBM-related modules support a family of hash-based file formats that store a mapping of strings to other strings.

The list of modules described in this chapter is:

- `pickle` — Python object serialization
  - Relationship to other Python modules
    - Comparison with `marshal`
    - Comparison with `json`
  - Data stream format
  - Module Interface
  - What can be pickled and unpickled?
  - Pickling Class Instances
    - Persistence of External Objects
    - Dispatch Tables
    - Handling Stateful Objects
  - Custom Reduction for Types, Functions, and Other Objects
  - Out-of-band Buffers
    - Provider API
    - Consumer API
    - Example
  - Restricting Globals
  - Performance

- Examples
- **copyreg** — Register **pickle** support functions
  - Example
- **shelve** — Python object persistence
  - Restrictions
  - Example
- **marshal** — Internal Python object serialization
- **dbm** — Interfaces to Unix “databases”
  - **dbm.gnu** — GNU’s reinterpretation of dbm
  - **dbm.ndbm** — Interface based on ndbm
  - **dbm.dumb** — Portable DBM implementation
- **sqlite3** — DB-API 2.0 interface for SQLite databases
  - Tutorial
  - Reference
    - Module functions
    - Module constants
    - Connection objects
    - Cursor objects
    - Row objects
    - Blob objects
    - PrepareProtocol objects
    - Exceptions
    - SQLite and Python types
    - Default adapters and converters
  - How-to guides
    - How to use placeholders to bind values in SQL queries
    - How to adapt custom Python types to SQLite values
    - How to write adaptable objects

- How to register adapter callables
  - How to convert SQLite values to custom Python types
  - Adapter and converter recipes
  - How to use connection shortcut methods
  - How to use the connection context manager
  - How to work with SQLite URIs
  - How to create and use row factories
- Explanation
    - Transaction control

# `pickle` — Python object serialization

**Source code:** [Lib/pickle.py](https://github.com/python/cpython/tree/3.11/Lib/pickle.py) [https://github.com/python/cpython/tree/3.11/Lib/pickle.py]

---

The `pickle` module implements binary protocols for serializing and de-serializing a Python object structure. “*Pickling*” is the process whereby a Python object hierarchy is converted into a byte stream, and “*unpickling*” is the inverse operation, whereby a byte stream (from a [binary file](#) or [bytes-like object](#)) is converted back into an object hierarchy. Pickling (and unpickling) is alternatively known as “serialization”, “marshalling,” [1](#) or “flattening”; however, to avoid confusion, the terms used here are “pickling” and “unpickling”.

## Warning

The `pickle` module **is not secure**. Only unpickle data you trust.

It is possible to construct malicious pickle data which will **execute arbitrary code during unpickling**. Never unpickle data that could have come from an untrusted source, or that could have been tampered with.

Consider signing data with [hmac](#) if you need to ensure that it has not been tampered with.

Safer serialization formats such as [json](#) may be more appropriate if you are processing untrusted data. See [Comparison with json](#).

## Relationship to other Python modules

## Comparison with `marshal`

Python has a more primitive serialization module called `marshal`, but in general `pickle` should always be the preferred way to serialize Python objects. `marshal` exists primarily to support Python's `.pyc` files.

The `pickle` module differs from `marshal` in several significant ways:

- The `pickle` module keeps track of the objects it has already serialized, so that later references to the same object won't be serialized again. `marshal` doesn't do this.

This has implications both for recursive objects and object sharing. Recursive objects are objects that contain references to themselves. These are not handled by `marshal`, and in fact, attempting to marshal recursive objects will crash your Python interpreter. Object sharing happens when there are multiple references to the same object in different places in the object hierarchy being serialized. `pickle` stores such objects only once, and ensures that all other references point to the master copy. Shared objects remain shared, which can be very important for mutable objects.

- `marshal` cannot be used to serialize user-defined classes and their instances. `pickle` can save and restore class instances transparently, however the class definition must be importable and live in the same module as when the object was stored.
- The `marshal` serialization format is not guaranteed to be portable across Python versions. Because its primary job in life is to support `.pyc` files, the Python implementers reserve the right to change the serialization format in non-backwards compatible ways should the need arise. The `pickle` serialization format is guaranteed to be backwards compatible across Python releases provided a compatible pickle protocol is chosen and pickling and unpickling code deals with Python 2 to Python 3 type differences if your data is crossing that unique breaking change language boundary.

## Comparison with `json`

There are fundamental differences between the pickle protocols and [JSON \(JavaScript Object Notation\)](https://json.org) [https://json.org]:

- JSON is a text serialization format (it outputs unicode text, although most of the time it is then encoded to `utf-8`), while pickle is a binary serialization format;
- JSON is human-readable, while pickle is not;
- JSON is interoperable and widely used outside of the Python ecosystem, while pickle is Python-specific;
- JSON, by default, can only represent a subset of the Python built-in types, and no custom classes; pickle can represent an extremely large number of Python types (many of them automatically, by clever usage of Python's introspection facilities; complex cases can be tackled by implementing [specific object APIs](#));
- Unlike pickle, deserializing untrusted JSON does not in itself create an arbitrary code execution vulnerability.

### See also

The `json` module: a standard library module allowing JSON serialization and deserialization.

## Data stream format

The data format used by `pickle` is Python-specific. This has the advantage that there are no restrictions imposed by external standards such as JSON or XDR (which can't represent pointer sharing); however it means that non-Python programs may not be able to reconstruct pickled Python objects.

By default, the `pickle` data format uses a relatively compact binary representation. If you need optimal size characteristics, you can efficiently [compress](#) pickled data.

The module `pickletools` contains tools for analyzing data streams generated by `pickle`. `pickletools` source code has

extensive comments about opcodes used by pickle protocols.

There are currently 6 different protocols which can be used for pickling. The higher the protocol used, the more recent the version of Python needed to read the pickle produced.

- Protocol version 0 is the original “human-readable” protocol and is backwards compatible with earlier versions of Python.
- Protocol version 1 is an old binary format which is also compatible with earlier versions of Python.
- Protocol version 2 was introduced in Python 2.3. It provides much more efficient pickling of [new-style classes](#). Refer to [PEP 307](#) [<https://peps.python.org/pep-0307/>] for information about improvements brought by protocol 2.
- Protocol version 3 was added in Python 3.0. It has explicit support for [bytes](#) objects and cannot be unpickled by Python 2.x. This was the default protocol in Python 3.0–3.7.
- Protocol version 4 was added in Python 3.4. It adds support for very large objects, pickling more kinds of objects, and some data format optimizations. It is the default protocol starting with Python 3.8. Refer to [PEP 3154](#) [<https://peps.python.org/pep-3154/>] for information about improvements brought by protocol 4.
- Protocol version 5 was added in Python 3.8. It adds support for out-of-band data and speedup for in-band data. Refer to [PEP 574](#) [<https://peps.python.org/pep-0574/>] for information about improvements brought by protocol 5.

## Note

Serialization is a more primitive notion than persistence; although [pickle](#) reads and writes file objects, it does not handle the issue of naming persistent objects, nor the (even more complicated) issue of concurrent access to persistent objects. The [pickle](#) module can transform a complex object into a byte stream and it can transform the byte stream into an object with the same internal structure. Perhaps the most obvious thing to do with these byte streams is to write them onto a file, but it is also conceivable to send them across a network or store them in a database. The [shelve](#) module provides a simple interface to

pickle and unpickle objects on DBM-style database files.

## Module Interface

To serialize an object hierarchy, you simply call the `dumps()` function. Similarly, to de-serialize a data stream, you call the `loads()` function. However, if you want more control over serialization and de-serialization, you can create a `Pickler` or an `Unpickler` object, respectively.

The `pickle` module provides the following constants:

`pickle.HIGHEST_PROTOCOL`

An integer, the highest [protocol version](#) available. This value can be passed as a *protocol* value to functions `dump()` and `dumps()` as well as the `Pickler` constructor.

`pickle.DEFAULT_PROTOCOL`

An integer, the default [protocol version](#) used for pickling. May be less than `HIGHEST_PROTOCOL`. Currently the default protocol is 4, first introduced in Python 3.4 and incompatible with previous versions.

*Changed in version 3.0:* The default protocol is 3.

*Changed in version 3.8:* The default protocol is 4.

The `pickle` module provides the following functions to make the pickling process more convenient:

`pickle.dump(obj, file, protocol=None, *, fix_imports=True, buffer_callback=None)`

Write the pickled representation of the object *obj* to the open [file object](#) *file*. This is equivalent to `Pickler(file, protocol).dump(obj)`.

Arguments *file*, *protocol*, *fix\_imports* and *buffer\_callback* have the same meaning as in the `Pickler` constructor.

*Changed in version 3.8:* The `buffer_callback` argument was added.

```
pickle.dumps(obj, protocol=None, *, fix_imports=True,  
buffer_callback=None)
```

Return the pickled representation of the object `obj` as a **bytes** object, instead of writing it to a file.

Arguments `protocol`, `fix_imports` and `buffer_callback` have the same meaning as in the **Pickler** constructor.

*Changed in version 3.8:* The `buffer_callback` argument was added.

```
pickle.load(file, *, fix_imports=True, encoding='ASCII', errors='strict',  
buffers=None)
```

Read the pickled representation of an object from the open **file object** `file` and return the reconstituted object hierarchy specified therein. This is equivalent to `Unpickler(file).load()`.

The protocol version of the pickle is detected automatically, so no protocol argument is needed. Bytes past the pickled representation of the object are ignored.

Arguments `file`, `fix_imports`, `encoding`, `errors`, `strict` and `buffers` have the same meaning as in the **Unpickler** constructor.

*Changed in version 3.8:* The `buffers` argument was added.

```
pickle.loads(data, /, *, fix_imports=True, encoding='ASCII',  
errors='strict', buffers=None)
```

Return the reconstituted object hierarchy of the pickled representation `data` of an object. `data` must be a **bytes-like object**.

The protocol version of the pickle is detected automatically, so no protocol argument is needed. Bytes past the pickled representation of the object are ignored.

Arguments *fix\_imports*, *encoding*, *errors*, *strict* and *buffers* have the same meaning as in the **Unpickler** constructor.

*Changed in version 3.8:* The *buffers* argument was added.

The **pickle** module defines three exceptions:

*exception* pickle.PickleError

Common base class for the other pickling exceptions. It inherits **Exception**.

*exception* pickle.PicklingError

Error raised when an unpicklable object is encountered by **Pickler**. It inherits **PickleError**.

Refer to [What can be pickled and unpickled?](#) to learn what kinds of objects can be pickled.

*exception* pickle.UnpicklingError

Error raised when there is a problem unpickling an object, such as a data corruption or a security violation. It inherits **PickleError**.

Note that other exceptions may also be raised during unpickling, including (but not necessarily limited to) **AttributeError**, **EOFError**, **ImportError**, and **IndexError**.

The **pickle** module exports three classes, **Pickler**, **Unpickler** and **PickleBuffer**:

```
class pickle.Pickler(file, protocol=None, *, fix_imports=True,
buffer_callback=None)
```

This takes a binary file for writing a pickle data stream.

The optional *protocol* argument, an integer, tells the pickler to use the given protocol; supported protocols are 0 to **HIGHEST\_PROTOCOL**. If not specified, the default is **DEFAULT\_PROTOCOL**. If a negative number is specified, **HIGHEST\_PROTOCOL** is selected.

The *file* argument must have a `write()` method that accepts a single bytes argument. It can thus be an on-disk file opened for binary writing, an `io.BytesIO` instance, or any other custom object that meets this interface.

If *fix\_imports* is true and *protocol* is less than 3, pickle will try to map the new Python 3 names to the old module names used in Python 2, so that the pickle data stream is readable with Python 2.

If *buffer\_callback* is None (the default), buffer views are serialized into *file* as part of the pickle stream.

If *buffer\_callback* is not None, then it can be called any number of times with a buffer view. If the callback returns a false value (such as None), the given buffer is `out-of-band`; otherwise the buffer is serialized in-band, i.e. inside the pickle stream.

It is an error if *buffer\_callback* is not None and *protocol* is None or smaller than 5.

*Changed in version 3.8:* The *buffer\_callback* argument was added.

`dump(obj)`

Write the pickled representation of *obj* to the open file object given in the constructor.

`persistent_id(obj)`

Do nothing by default. This exists so a subclass can override it.

If `persistent_id()` returns `None`, *obj* is pickled as usual. Any other value causes `Pickler` to emit the returned value as a persistent ID for *obj*. The meaning of this persistent ID should be defined by `Unpickler.persistent_load()`. Note that the value returned by `persistent_id()` cannot itself have a persistent ID.

See [Persistence of External Objects](#) for details and examples of uses.

## `dispatch_table`

A pickler object's dispatch table is a registry of *reduction functions* of the kind which can be declared using `copyreg.pickle()`. It is a mapping whose keys are classes and whose values are reduction functions. A reduction function takes a single argument of the associated class and should conform to the same interface as a `__reduce__()` method.

By default, a pickler object will not have a `dispatch_table` attribute, and it will instead use the global dispatch table managed by the `copyreg` module. However, to customize the pickling for a specific pickler object one can set the `dispatch_table` attribute to a dict-like object. Alternatively, if a subclass of `Pickler` has a `dispatch_table` attribute then this will be used as the default dispatch table for instances of that class.

See [Dispatch Tables](#) for usage examples.

*New in version 3.3.*

## `reducer_override(obj)`

Special reducer that can be defined in `Pickler` subclasses. This method has priority over any reducer in the `dispatch_table`. It should conform to the same interface as a `__reduce__()` method, and can optionally return `NotImplemented` to fallback on `dispatch_table`-registered reducers to pickle `obj`.

For a detailed example, see [Custom Reduction for Types, Functions, and Other Objects](#).

*New in version 3.8.*

## `fast`

Deprecated. Enable fast mode if set to a true value. The fast mode disables the usage of memo, therefore speeding the pickling process by not generating superfluous PUT opcodes. It should not be used with self-referential objects, doing otherwise will cause **Pickler** to recurse infinitely.

Use **`pickletools.optimize()`** if you need more compact pickles.

```
class pickle.Unpickler(file, *, fix_imports = True, encoding = 'ASCII',  
errors = 'strict', buffers = None)
```

This takes a binary file for reading a pickle data stream.

The protocol version of the pickle is detected automatically, so no protocol argument is needed.

The argument *file* must have three methods, a `read()` method that takes an integer argument, a `readinto()` method that takes a buffer argument and a `readline()` method that requires no arguments, as in the **`io.BufferedReader`** interface. Thus *file* can be an on-disk file opened for binary reading, an **`io.BytesIO`** object, or any other custom object that meets this interface.

The optional arguments *fix\_imports*, *encoding* and *errors* are used to control compatibility support for pickle stream generated by Python 2. If *fix\_imports* is true, pickle will try to map the old Python 2 names to the new names used in Python 3. The *encoding* and *errors* tell pickle how to decode 8-bit string instances pickled by Python 2; these default to 'ASCII' and 'strict', respectively. The *encoding* can be 'bytes' to read these 8-bit string instances as bytes objects. Using *encoding='latin1'* is required for unpickling NumPy arrays and instances of **`datetime`**, **`date`** and **`time`** pickled by Python 2.

If *buffers* is None (the default), then all data necessary for deserialization must be contained in the pickle stream. This means that the *buffer\_callback* argument was None when a

**Pickler** was instantiated (or when `dump()` or `dumps()` was called).

If *buffers* is not None, it should be an iterable of buffer-enabled objects that is consumed each time the pickle stream references an **out-of-band** buffer view. Such buffers have been given in order to the *buffer\_callback* of a Pickler object.

*Changed in version 3.8:* The *buffers* argument was added.

`load()`

Read the pickled representation of an object from the open file object given in the constructor, and return the reconstituted object hierarchy specified therein. Bytes past the pickled representation of the object are ignored.

`persistent_load(pid)`

Raise an **UnpicklingError** by default.

If defined, `persistent_load()` should return the object specified by the persistent ID *pid*. If an invalid persistent ID is encountered, an **UnpicklingError** should be raised.

See **Persistence of External Objects** for details and examples of uses.

`find_class(module, name)`

Import *module* if necessary and return the object called *name* from it, where the *module* and *name* arguments are **str** objects. Note, unlike its name suggests, `find_class()` is also used for finding functions.

Subclasses may override this to gain control over what type of objects and how they can be loaded, potentially reducing security risks. Refer to **Restricting Globals** for details.

Raises an **auditing event** `pickle.find_class` with

arguments module, name.

*class* pickle.PickleBuffer(*buffer*)

A wrapper for a buffer representing picklable data. *buffer* must be a [buffer-providing](#) object, such as a [bytes-like object](#) or a N-dimensional array.

**PickleBuffer** is itself a buffer provider, therefore it is possible to pass it to other APIs expecting a buffer-providing object, such as [memoryview](#).

**PickleBuffer** objects can only be serialized using pickle protocol 5 or higher. They are eligible for [out-of-band serialization](#).

*New in version 3.8.*

*raw()*

Return a [memoryview](#) of the memory area underlying this buffer. The returned object is a one-dimensional, C-contiguous memoryview with format `B` (unsigned bytes). **BufferError** is raised if the buffer is neither C- nor Fortran-contiguous.

*release()*

Release the underlying buffer exposed by the **PickleBuffer** object.

## What can be pickled and unpickled?

The following types can be pickled:

- `None`, `True`, and `False`;
- integers, floating-point numbers, complex numbers;
- strings, bytes, bytearray;
- tuples, lists, sets, and dictionaries containing only picklable objects;
- functions (built-in and user-defined) accessible from the top level of a module (using [def](#), not [lambda](#));

- classes accessible from the top level of a module;
- instances of such classes whose the result of calling `__getstate__()` is picklable (see section [Pickling Class Instances](#) for details).

Attempts to pickle unpicklable objects will raise the [PicklingError](#) exception; when this happens, an unspecified number of bytes may have already been written to the underlying file. Trying to pickle a highly recursive data structure may exceed the maximum recursion depth, a [RecursionError](#) will be raised in this case. You can carefully raise this limit with `sys.setrecursionlimit()`.

Note that functions (built-in and user-defined) are pickled by fully [qualified name](#), not by value. <sup>2</sup> This means that only the function name is pickled, along with the name of the containing module and classes. Neither the function's code, nor any of its function attributes are pickled. Thus the defining module must be importable in the unpickling environment, and the module must contain the named object, otherwise an exception will be raised. <sup>3</sup>

Similarly, classes are pickled by fully qualified name, so the same restrictions in the unpickling environment apply. Note that none of the class's code or data is pickled, so in the following example the class attribute `attr` is not restored in the unpickling environment:

```
class Foo:
    attr = 'A class attribute'

picklestring = pickle.dumps(Foo)
```

These restrictions are why picklable functions and classes must be defined at the top level of a module.

Similarly, when class instances are pickled, their class's code and data are not pickled along with them. Only the instance data are pickled. This is done on purpose, so you can fix bugs in a class or add methods to the class and still load objects that were created with an earlier version of the class. If you plan to have long-lived objects that will see many versions of a class, it may be worthwhile to put a version number in the objects so that suitable conversions

can be made by the class's `__setstate__()` method.

## Pickling Class Instances

In this section, we describe the general mechanisms available to you to define, customize, and control how class instances are pickled and unpickled.

In most cases, no additional code is needed to make instances picklable. By default, pickle will retrieve the class and the attributes of an instance via introspection. When a class instance is unpickled, its `__init__()` method is usually *not* invoked. The default behaviour first creates an uninitialized instance and then restores the saved attributes. The following code shows an implementation of this behaviour:

```
def save(obj):
    return (obj.__class__, obj.__dict__)

def restore(cls, attributes):
    obj = cls.__new__(cls)
    obj.__dict__.update(attributes)
    return obj
```

Classes can alter the default behaviour by providing one or several special methods:

`object.__getnewargs_ex__()`

In protocols 2 and newer, classes that implements the `__getnewargs_ex__()` method can dictate the values passed to the `__new__()` method upon unpickling. The method must return a pair `(args, kwargs)` where *args* is a tuple of positional arguments and *kwargs* a dictionary of named arguments for constructing the object. Those will be passed to the `__new__()` method upon unpickling.

You should implement this method if the `__new__()` method of your class requires keyword-only arguments. Otherwise, it is recommended for compatibility to implement

`__getnewargs__()`.

*Changed in version 3.6:* `__getnewargs_ex__()` is now used in protocols 2 and 3.

`object.__getnewargs__()`

This method serves a similar purpose as

`__getnewargs_ex__()`, but supports only positional arguments. It must return a tuple of arguments `args` which will be passed to the `__new__()` method upon unpickling.

`__getnewargs__()` will not be called if `__getnewargs_ex__()` is defined.

*Changed in version 3.6:* Before Python 3.6, `__getnewargs__()` was called instead of `__getnewargs_ex__()` in protocols 2 and 3.

`object.__getstate__()`

Classes can further influence how their instances are pickled by overriding the method `__getstate__()`. It is called and the returned object is pickled as the contents for the instance, instead of a default state. There are several cases:

- For a class that has no instance `__dict__` and no `__slots__`, the default state is `None`.
- For a class that has an instance `__dict__` and no `__slots__`, the default state is `self.__dict__`.
- For a class that has an instance `__dict__` and `__slots__`, the default state is a tuple consisting of two dictionaries: `self.__dict__`, and a dictionary mapping slot names to slot values. Only slots that have a value are included in the latter.
- For a class that has `__slots__` and no instance `__dict__`, the default state is a tuple whose first item is `None` and whose second item is a dictionary mapping slot names to slot values described in the previous bullet.

*Changed in version 3.11:* Added the default implementation of

the `__getstate__()` method in the `object` class.

`object._setstate_(state)`

Upon unpickling, if the class defines `__setstate__()`, it is called with the unpickled state. In that case, there is no requirement for the state object to be a dictionary. Otherwise, the pickled state must be a dictionary and its items are assigned to the new instance's dictionary.

### Note

If `__getstate__()` returns a false value, the `__setstate__()` method will not be called upon unpickling.

Refer to the section [Handling Stateful Objects](#) for more information about how to use the methods `__getstate__()` and `__setstate__()`.

### Note

At unpickling time, some methods like `__getattr__()`, `__getattribute__()`, or `__setattr__()` may be called upon the instance. In case those methods rely on some internal invariant being true, the type should implement `__new__()` to establish such an invariant, as `__init__()` is not called when unpickling an instance.

As we shall see, pickle does not use directly the methods described above. In fact, these methods are part of the copy protocol which implements the `__reduce__()` special method. The copy protocol provides a unified interface for retrieving the data necessary for pickling and copying objects. [4](#)

Although powerful, implementing `__reduce__()` directly in your classes is error prone. For this reason, class designers should use the high-level interface (i.e., `__getnewargs_ex__()`, `__getstate__()` and `__setstate__()`) whenever possible. We

will show, however, cases where using `__reduce__()` is the only option or leads to more efficient pickling or both.

`object.__reduce__()`

The interface is currently defined as follows. The `__reduce__()` method takes no argument and shall return either a string or preferably a tuple (the returned object is often referred to as the “reduce value”).

If a string is returned, the string should be interpreted as the name of a global variable. It should be the object’s local name relative to its module; the pickle module searches the module namespace to determine the object’s module. This behaviour is typically useful for singletons.

When a tuple is returned, it must be between two and six items long. Optional items can either be omitted, or `None` can be provided as their value. The semantics of each item are in order:

- A callable object that will be called to create the initial version of the object.
- A tuple of arguments for the callable object. An empty tuple must be given if the callable does not accept any argument.
- Optionally, the object’s state, which will be passed to the object’s `__setstate__()` method as previously described. If the object has no such method then, the value must be a dictionary and it will be added to the object’s `__dict__` attribute.
- Optionally, an iterator (and not a sequence) yielding successive items. These items will be appended to the object either using `obj.append(item)` or, in batch, using `obj.extend(list_of_items)`. This is primarily used for list subclasses, but may be used by other classes as long as they have `append()` and `extend()` methods with the appropriate signature. (Whether `append()` or `extend()` is used depends on

which pickle protocol version is used as well as the number of items to append, so both must be supported.)

- Optionally, an iterator (not a sequence) yielding successive key-value pairs. These items will be stored to the object using `obj[key] = value`. This is primarily used for dictionary subclasses, but may be used by other classes as long as they implement `__setitem__()`.
- Optionally, a callable with a `(obj, state)` signature. This callable allows the user to programmatically control the state-updating behavior of a specific object, instead of using `obj`'s static `__setstate__()` method. If not `None`, this callable will have priority over `obj`'s `__setstate__()`.

*New in version 3.8:* The optional sixth tuple item, `(obj, state)`, was added.

`object._reduce_ex(protocol)`

Alternatively, a `__reduce_ex__()` method may be defined. The only difference is this method should take a single integer argument, the protocol version. When defined, pickle will prefer it over the `__reduce__()` method. In addition, `__reduce__()` automatically becomes a synonym for the extended version. The main use for this method is to provide backwards-compatible reduce values for older Python releases.

## Persistence of External Objects

For the benefit of object persistence, the `pickle` module supports the notion of a reference to an object outside the pickled data stream. Such objects are referenced by a persistent ID, which should be either a string of alphanumeric characters (for protocol 0) [5](#) or just an arbitrary object (for any newer protocol).

The resolution of such persistent IDs is not defined by the `pickle`

module; it will delegate this resolution to the user-defined methods on the pickler and unpickler, `persistent_id()` and `persistent_load()` respectively.

To pickle objects that have an external persistent ID, the pickler must have a custom `persistent_id()` method that takes an object as an argument and returns either `None` or the persistent ID for that object. When `None` is returned, the pickler simply pickles the object as normal. When a persistent ID string is returned, the pickler will pickle that object, along with a marker so that the unpickler will recognize it as a persistent ID.

To unpickle external objects, the unpickler must have a custom `persistent_load()` method that takes a persistent ID object and returns the referenced object.

Here is a comprehensive example presenting how persistent ID can be used to pickle external objects by reference.

```
# Simple example presenting how persistent ID can be used to pickle
# external objects by reference.
```

```
import pickle
import sqlite3
from collections import namedtuple
```

```
# Simple class representing a record in our database.
MemoRecord = namedtuple("MemoRecord", "key, task")
```

```
class DBPickler(pickle.Pickler):
```

```
    def persistent_id(self, obj):
        # Instead of pickling MemoRecord as a regular class instance,
        # persist it as a persistent ID.
        if isinstance(obj, MemoRecord):
            # Here, our persistent ID is simply a tuple, (key, task),
            # where key is the key, which refers to a specific record in
            # the database.
            return ("MemoRecord", obj.key)
        else:
            # If obj does not have a persistent ID, return None.
```

```
    # needs to be pickled as usual.
    return None
```

```
class DBUnpickler(pickle.Unpickler):
```

```
    def __init__(self, file, connection):
        super().__init__(file)
        self.connection = connection
```

```
    def persistent_load(self, pid):
        # This method is invoked whenever a persistent ID is loaded.
        # Here, pid is the tuple returned by DBPickler.
        cursor = self.connection.cursor()
        type_tag, key_id = pid
        if type_tag == "MemoRecord":
            # Fetch the referenced record from the database.
            cursor.execute("SELECT * FROM memos WHERE key_id = %s" % key_id)
            key, task = cursor.fetchone()
            return MemoRecord(key, task)
        else:
            # Always raises an error if you cannot return a persistent object.
            # Otherwise, the unpickler will think None is the object.
            # by the persistent ID.
            raise pickle.UnpicklingError("unsupported persistent object")
```

```
def main():
```

```
    import io
    import pprint
```

```
    # Initialize and populate our database.
    conn = sqlite3.connect(":memory:")
    cursor = conn.cursor()
    cursor.execute("CREATE TABLE memos(key INTEGER PRIMARY KEY, task TEXT)")
    tasks = (
        'give food to fish',
        'prepare group meeting',
    )
```

```

        'fight with a zebra',
    )
    for task in tasks:
        cursor.execute("INSERT INTO memos VALUES(NULL, ?)")

    # Fetch the records to be pickled.
    cursor.execute("SELECT * FROM memos")
    memos = [MemoRecord(key, task) for key, task in cursor.fetchall()]
    # Save the records using our custom DBPickler.
    file = io.BytesIO()
    DBPickler(file).dump(memos)

    print("Pickled records:")
    pprint.pprint(memos)

    # Update a record, just for good measure.
    cursor.execute("UPDATE memos SET task='learn italian'")

    # Load the records from the pickle data stream.
    file.seek(0)
    memos = DBUnpickler(file, conn).load()

    print("Unpickled records:")
    pprint.pprint(memos)

if __name__ == '__main__':
    main()

```

## Dispatch Tables

If one wants to customize pickling of some classes without disturbing any other code which depends on pickling, then one can create a pickler with a private dispatch table.

The global dispatch table managed by the `copyreg` module is available as `copyreg.dispatch_table`. Therefore, one may choose to use a modified copy of `copyreg.dispatch_table` as a private dispatch table.

For example

```
f = io.BytesIO()
p = pickle.Pickler(f)
p.dispatch_table = copyreg.dispatch_table.copy()
p.dispatch_table[SomeClass] = reduce_SomeClass
```

creates an instance of `pickle.Pickler` with a private dispatch table which handles the `SomeClass` class specially. Alternatively, the code

```
class MyPickler(pickle.Pickler):
    dispatch_table = copyreg.dispatch_table.copy()
    dispatch_table[SomeClass] = reduce_SomeClass
f = io.BytesIO()
p = MyPickler(f)
```

does the same but all instances of `MyPickler` will by default share the private dispatch table. On the other hand, the code

```
copyreg.pickle(SomeClass, reduce_SomeClass)
f = io.BytesIO()
p = pickle.Pickler(f)
```

modifies the global dispatch table shared by all users of the `copyreg` module.

## Handling Stateful Objects

Here's an example that shows how to modify pickling behavior for a class. The `TextReader` class opens a text file, and returns the line number and line contents each time its `readline()` method is called. If a `TextReader` instance is pickled, all attributes *except* the file object member are saved. When the instance is unpickled, the file is reopened, and reading resumes from the last location. The `__setstate__()` and `__getstate__()` methods are used to implement this behavior.

```
class TextReader:
    """Print and number lines in a text file."""
```

```

def __init__(self, filename):
    self.filename = filename
    self.file = open(filename)
    self.lineno = 0

def readline(self):
    self.lineno += 1
    line = self.file.readline()
    if not line:
        return None
    if line.endswith('\n'):
        line = line[:-1]
    return "%i: %s" % (self.lineno, line)

def __getstate__(self):
    # Copy the object's state from self.__dict__ which
    # all our instance attributes. Always use the dict
    # method to avoid modifying the original state.
    state = self.__dict__.copy()
    # Remove the unpicklable entries.
    del state['file']
    return state

def __setstate__(self, state):
    # Restore instance attributes (i.e., filename and
    self.__dict__.update(state)
    # Restore the previously opened file's state. To
    # reopen it and read from it until the line count
    file = open(self.filename)
    for _ in range(self.lineno):
        file.readline()
    # Finally, save the file.
    self.file = file

```

A sample usage might be something like this:

```

>>> reader = TextReader("hello.txt")
>>> reader.readline()

```

```
'1: Hello world!'
>>> reader.readline()
'2: I am line number two.'
>>> new_reader = pickle.loads(pickle.dumps(reader))
>>> new_reader.readline()
'3: Goodbye!'
```

## Custom Reduction for Types, Functions, and Other Objects

*New in version 3.8.*

Sometimes, `dispatch_table` may not be flexible enough. In particular we may want to customize pickling based on another criterion than the object's type, or we may want to customize the pickling of functions and classes.

For those cases, it is possible to subclass from the `Pickler` class and implement a `reducer_override()` method. This method can return an arbitrary reduction tuple (see `__reduce__()`). It can alternatively return `NotImplemented` to fallback to the traditional behavior.

If both the `dispatch_table` and `reducer_override()` are defined, then `reducer_override()` method takes priority.

### Note

For performance reasons, `reducer_override()` may not be called for the following objects: `None`, `True`, `False`, and exact instances of `int`, `float`, `bytes`, `str`, `dict`, `set`, `frozenset`, `list` and `tuple`.

Here is a simple example where we allow pickling and reconstructing a given class:

```
import io
import pickle
```

```

class MyClass:
    my_attribute = 1

class MyPickler(pickle.Pickler):
    def reducer_override(self, obj):
        """Custom reducer for MyClass."""
        if getattr(obj, "__name__", None) == "MyClass":
            return type, (obj.__name__, obj.__bases__,
                           {'my_attribute': obj.my_attribute})
        else:
            # For any other object, fallback to usual reducer
            return NotImplemented

f = io.BytesIO()
p = MyPickler(f)
p.dump(MyClass)

del MyClass

unpickled_class = pickle.loads(f.getvalue())

assert isinstance(unpickled_class, type)
assert unpickled_class.__name__ == "MyClass"
assert unpickled_class.my_attribute == 1

```

## Out-of-band Buffers

*New in version 3.8.*

In some contexts, the `pickle` module is used to transfer massive amounts of data. Therefore, it can be important to minimize the number of memory copies, to preserve performance and resource consumption. However, normal operation of the `pickle` module, as it transforms a graph-like structure of objects into a sequential stream of bytes, intrinsically involves copying data to and from the pickle stream.

This constraint can be eschewed if both the *provider* (the implementation of the object types to be transferred) and the

*consumer* (the implementation of the communications system) support the out-of-band transfer facilities provided by pickle protocol 5 and higher.

## Provider API

The large data objects to be pickled must implement a `__reduce_ex__()` method specialized for protocol 5 and higher, which returns a `PickleBuffer` instance (instead of e.g. a `bytes` object) for any large data.

A `PickleBuffer` object *signals* that the underlying buffer is eligible for out-of-band data transfer. Those objects remain compatible with normal usage of the `pickle` module. However, consumers can also opt-in to tell `pickle` that they will handle those buffers by themselves.

## Consumer API

A communications system can enable custom handling of the `PickleBuffer` objects generated when serializing an object graph.

On the sending side, it needs to pass a *buffer\_callback* argument to `Pickler` (or to the `dump()` or `dumps()` function), which will be called with each `PickleBuffer` generated while pickling the object graph. Buffers accumulated by the *buffer\_callback* will not see their data copied into the pickle stream, only a cheap marker will be inserted.

On the receiving side, it needs to pass a *buffers* argument to `Unpickler` (or to the `load()` or `loads()` function), which is an iterable of the buffers which were passed to *buffer\_callback*. That iterable should produce buffers in the same order as they were passed to *buffer\_callback*. Those buffers will provide the data expected by the reconstructors of the objects whose pickling produced the original `PickleBuffer` objects.

Between the sending side and the receiving side, the communications system is free to implement its own transfer mechanism for out-of-band buffers. Potential optimizations include

the use of shared memory or datatype-dependent compression.

## Example

Here is a trivial example where we implement a `bytearray` subclass able to participate in out-of-band buffer pickling:

```
class ZeroCopyByteArray(bytearray):

    def __reduce_ex__(self, protocol):
        if protocol >= 5:
            return type(self).__reconstruct, (PickleBuffer, self)
        else:
            # PickleBuffer is forbidden with pickle protocol < 5
            return type(self).__reconstruct, (bytearray, self)

    @classmethod
    def _reconstruct(cls, obj):
        with memoryview(obj) as m:
            # Get a handle over the original buffer object
            obj = m.obj
            if type(obj) is cls:
                # Original buffer object is a ZeroCopyByteArray
                # as-is.
                return obj
            else:
                return cls(obj)
```

The reconstructor (the `_reconstruct` class method) returns the buffer's providing object if it has the right type. This is an easy way to simulate zero-copy behaviour on this toy example.

On the consumer side, we can pickle those objects the usual way, which when unserialized will give us a copy of the original object:

```
b = ZeroCopyByteArray(b"abc")
data = pickle.dumps(b, protocol=5)
new_b = pickle.loads(data)
print(b == new_b)  # True
```

```
print(b is new_b)    # False: a copy was made
```

But if we pass a *buffer\_callback* and then give back the accumulated buffers when unserializing, we are able to get back the original object:

```
b = ZeroCopyByteArray(b"abc")
buffers = []
data = pickle.dumps(b, protocol=5, buffer_callback=buffer_callback)
new_b = pickle.loads(data, buffers=buffers)
print(b == new_b)    # True
print(b is new_b)    # True: no copy was made
```

This example is limited by the fact that **bytearray** allocates its own memory: you cannot create a **bytearray** instance that is backed by another object's memory. However, third-party datatypes such as NumPy arrays do not have this limitation, and allow use of zero-copy pickling (or making as few copies as possible) when transferring between distinct processes or systems.

**PEP 574** [<https://peps.python.org/pep-0574/>] – Pickle protocol 5 with out-of-band data

## Restricting Globals

By default, unpickling will import any class or function that it finds in the pickle data. For many applications, this behaviour is unacceptable as it permits the unpickler to import and invoke arbitrary code. Just consider what this hand-crafted pickle data stream does when loaded:

```
>>> import pickle
>>> pickle.loads(b"cos\nsystem\n(S'echo hello world'\ntr\nhello world\n0")
```

In this example, the unpickler imports the **os.system()** function

and then apply the string argument “echo hello world”. Although this example is inoffensive, it is not difficult to imagine one that could damage your system.

For this reason, you may want to control what gets unpickled by customizing `Unpickler.find_class()`. Unlike its name suggests, `Unpickler.find_class()` is called whenever a global (i.e., a class or a function) is requested. Thus it is possible to either completely forbid globals or restrict them to a safe subset.

Here is an example of an unpickler allowing only few safe classes from the `builtins` module to be loaded:

```
import builtins
import io
import pickle

safe_builtins = {
    'range',
    'complex',
    'set',
    'frozenset',
    'slice',
}

class RestrictedUnpickler(pickle.Unpickler):

    def find_class(self, module, name):
        # Only allow safe classes from builtins.
        if module == "builtins" and name in safe_builtins:
            return getattr(builtins, name)
        # Forbid everything else.
        raise pickle.UnpicklingError("global '%s.%s' is
                                      not allowed")

def restricted_loads(s):
    """Helper function analogous to pickle.loads()."""
    return RestrictedUnpickler(io.BytesIO(s)).load()
```

A sample usage of our unpickler working as intended:

```
>>> restricted_loads(pickle.dumps([1, 2, range(15)]))
[1, 2, range(0, 15)]
>>> restricted_loads(b"cos\nsystem\n(S'echo hello world'
Traceback (most recent call last):
...
pickle.UnpicklingError: global 'os.system' is forbidden
>>> restricted_loads(b'cbuiltins\neval\n'
...
b'(S\'getattr(__import__("os"), "sy
...
b'("echo hello world")\'\ntR.')
```

As our examples shows, you have to be careful with what you allow to be unpickled. Therefore if security is a concern, you may want to consider alternatives such as the marshalling API in [xmlrpc.client](#) or third-party solutions.

## Performance

Recent versions of the pickle protocol (from protocol 2 and upwards) feature efficient binary encodings for several common features and built-in types. Also, the [pickle](#) module has a transparent optimizer written in C.

## Examples

For the simplest code, use the [dump\(\)](#) and [load\(\)](#) functions.

```
import pickle

# An arbitrary collection of objects supported by pickle
data = {
    'a': [1, 2.0, 3+4j],
    'b': ("character string", b"byte string"),
    'c': {None, True, False}
}
```

```
with open('data.pickle', 'wb') as f:
    # Pickle the 'data' dictionary using the highest protocol
    pickle.dump(data, f, pickle.HIGHEST_PROTOCOL)
```

The following example reads the resulting pickled data.

```
import pickle

with open('data.pickle', 'rb') as f:
    # The protocol version used is detected automatically
    # have to specify it.
    data = pickle.load(f)
```

## See also

### Module [copyreg](#)

Pickle interface constructor registration for extension types.

### Module [pickletools](#)

Tools for working with and analyzing pickled data.

### Module [shelve](#)

Indexed databases of objects; uses [pickle](#).

### Module [copy](#)

Shallow and deep object copying.

### Module [marshal](#)

High-performance serialization of built-in types.

## Footnotes

1

Don't confuse this with the [marshal](#) module

2

This is why [lambda](#) functions cannot be pickled: all [lambda](#)

functions share the same name: `<lambda>`.

3

The exception raised will likely be an `ImportError` or an `AttributeError` but it could be something else.

4

The `copy` module uses this protocol for shallow and deep copying operations.

5

The limitation on alphanumeric characters is due to the fact that persistent IDs in protocol 0 are delimited by the newline character. Therefore if any kind of newline characters occurs in persistent IDs, the resulting pickled data will become unreadable.

# copyreg — Register pickle support functions

Source code: [Lib/copyreg.py](https://github.com/python/cpython/tree/3.11/Lib/copyreg.py) [https://github.com/python/cpython/tree/3.11/Lib/copyreg.py]

---

The `copyreg` module offers a way to define functions used while pickling specific objects. The `pickle` and `copy` modules use those functions when pickling/copying those objects. The module provides configuration information about object constructors which are not classes. Such constructors may be factory functions or class instances.

`copyreg.constructor(object)`

Declares *object* to be a valid constructor. If *object* is not callable (and hence not valid as a constructor), raises `TypeError`.

`copyreg.pickle(type, function, constructor_ob = None)`

Declares that *function* should be used as a “reduction” function for objects of type *type*. *function* must return either a string or a tuple containing between two and six elements. See the `dispatch_table` for more details on the interface of *function*.

The *constructor\_ob* parameter is a legacy feature and is now ignored, but if passed it must be a callable.

Note that the `dispatch_table` attribute of a pickler object or subclass of `pickle.Pickler` can also be used for declaring reduction functions.

## Example

The example below would like to show how to register a pickle function and how it will be used:

```
>>> import copyreg, copy, pickle
>>> class C:
...     def __init__(self, a):
...         self.a = a
...
>>> def pickle_c(c):
...     print("pickling a C instance...")
...     return C, (c.a,)
...
>>> copyreg.pickle(C, pickle_c)
>>> c = C(1)
>>> d = copy.copy(c)
pickling a C instance...
>>> p = pickle.dumps(c)
pickling a C instance...
```

# shelve — Python object persistence

**Source code:** [Lib/shelve.py](https://github.com/python/cpython/tree/3.11/Lib/shelve.py) [https://github.com/python/cpython/tree/3.11/Lib/shelve.py]

---

A “shelf” is a persistent, dictionary-like object. The difference with “dbm” databases is that the values (not the keys!) in a shelf can be essentially arbitrary Python objects — anything that the [pickle](#) module can handle. This includes most class instances, recursive data types, and objects containing lots of shared sub-objects. The keys are ordinary strings.

`shelve.open(filename, flag='c', protocol=None, writeback=False)`

Open a persistent dictionary. The filename specified is the base filename for the underlying database. As a side-effect, an extension may be added to the filename and more than one file may be created. By default, the underlying database file is opened for reading and writing. The optional *flag* parameter has the same interpretation as the *flag* parameter of [dbm.open\(\)](#).

By default, pickles created with [pickle.DEFAULT\\_PROTOCOL](#) are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter.

Because of Python semantics, a shelf cannot know when a mutable persistent-dictionary entry is modified. By default modified objects are written *only* when assigned to the shelf (see [Example](#)). If the optional *writeback* parameter is set to `True`, all entries accessed are also cached in memory, and written back on [sync\(\)](#) and [close\(\)](#); this can make it handier to mutate mutable entries in the persistent

dictionary, but, if many entries are accessed, it can consume vast amounts of memory for the cache, and it can make the close operation very slow since all accessed entries are written back (there is no way to determine which accessed entries are mutable, nor which ones were actually mutated).

*Changed in version 3.10:* `pickle.DEFAULT_PROTOCOL` is now used as the default pickle protocol.

*Changed in version 3.11:* Accepts `path-like object` for filename.

### Note

Do not rely on the shelf being closed automatically; always call `close()` explicitly when you don't need it any more, or use `shelve.open()` as a context manager:

```
with shelve.open('spam') as db:
    db['eggs'] = 'eggs'
```

### Warning

Because the `shelve` module is backed by `pickle`, it is insecure to load a shelf from an untrusted source. Like with `pickle`, loading a shelf can execute arbitrary code.

Shelf objects support most of methods and operations supported by dictionaries (except copying, constructors and operators `|` and `|` `=`). This eases the transition from dictionary based scripts to those requiring persistent storage.

Two additional methods are supported:

#### `Shelf.sync()`

Write back all entries in the cache if the shelf was opened with `writeback` set to `True`. Also empty the cache and synchronize the persistent dictionary on disk, if feasible. This is called automatically when the shelf is closed with

`close()`.

`Shelf.close()`

Synchronize and close the persistent *dict* object. Operations on a closed shelf will fail with a `ValueError`.

### See also

[Persistent dictionary recipe](https://code.activestate.com/recipes/576642/) [https://code.activestate.com/recipes/576642/] with widely supported storage formats and having the speed of native dictionaries.

## Restrictions

- The choice of which database package will be used (such as `dbm.ndbm` or `dbm.gnu`) depends on which interface is available. Therefore it is not safe to open the database directly using `dbm`. The database is also (unfortunately) subject to the limitations of `dbm`, if it is used — this means that (the pickled representation of) the objects stored in the database should be fairly small, and in rare cases key collisions may cause the database to refuse updates.
- The `shelve` module does not support *concurrent* read/write access to shelved objects. (Multiple simultaneous read accesses are safe.) When a program has a shelf open for writing, no other program should have it open for reading or writing. Unix file locking can be used to solve this, but this differs across Unix versions and requires knowledge about the database implementation used.

```
class shelve.Shelf(dict, protocol=None, writeback=False,  
keyencoding='utf-8')
```

A subclass of `collections.abc.MutableMapping` which stores pickled values in the *dict* object.

By default, pickles created with `pickle.DEFAULT_PROTOCOL` are used to serialize values.

The version of the pickle protocol can be specified with the *protocol* parameter. See the [pickle](#) documentation for a discussion of the pickle protocols.

If the *writeback* parameter is `True`, the object will hold a cache of all entries accessed and write them back to the *dict* at sync and close times. This allows natural operations on mutable entries, but can consume much more memory and make sync and close take a long time.

The *keyencoding* parameter is the encoding used to encode keys before they are used with the underlying dict.

A [Shelf](#) object can also be used as a context manager, in which case it will be automatically closed when the [with](#) block ends.

*Changed in version 3.2:* Added the *keyencoding* parameter; previously, keys were always encoded in UTF-8.

*Changed in version 3.4:* Added context manager support.

*Changed in version 3.10:* [pickle.DEFAULT\\_PROTOCOL](#) is now used as the default pickle protocol.

```
class shelve.BsdDbShelf(dict, protocol=None, writeback=False,
keyencoding='utf-8')
```

A subclass of [Shelf](#) which exposes `first()`, `next()`, `previous()`, `last()` and `set_location()` which are available in the third-party `bsddb` module from [pybsddb](https://www.jcea.es/programacion/pybsddb.htm) [https://www.jcea.es/programacion/pybsddb.htm] but not in other database modules. The *dict* object passed to the constructor must support those methods. This is generally accomplished by calling one of `bsddb.hashopen()`, `bsddb.btopen()` or `bsddb.rnopen()`. The optional *protocol*, *writeback*, and *keyencoding* parameters have the same interpretation as for the [Shelf](#) class.

```
class shelve.DbfilenameShelf(filename, flag='c', protocol=None,
writeback=False)
```

A subclass of `Shelf` which accepts a *filename* instead of a dict-like object. The underlying file will be opened using `dbm.open()`. By default, the file will be created and opened for both read and write. The optional *flag* parameter has the same interpretation as for the `open()` function. The optional *protocol* and *writeback* parameters have the same interpretation as for the `Shelf` class.

## Example

To summarize the interface (key is a string, data is an arbitrary object):

```
import shelve

d = shelve.open(filename)  # open -- file may get suffix
                           # library

d[key] = data              # store data at key (overwrite
                           # using an existing key)
data = d[key]              # retrieve a COPY of data at
                           # if no such key)
del d[key]                 # delete data stored at key
                           # if no such key)

flag = key in d             # true if the key exists
klist = list(d.keys())      # a list of all existing keys

# as d was opened WITHOUT writeback=True, beware:
d['xx'] = [0, 1, 2]         # this works as expected, but
d['xx'].append(3)           # *this doesn't!* -- d['xx']

# having opened d without writeback=True, you need to co
temp = d['xx']              # extracts the copy
temp.append(5)              # mutates the copy
d['xx'] = temp              # stores the copy right back,

# or, d=shelve.open(filename,writeback=True) would let y
```

```
# d['xx'].append(5) and have it work as expected, BUT it
# consume more memory and make the d.close() operation s

d.close()                                # close it
```

## See also

### Module [dbm](#)

Generic interface to dbm-style databases.

### Module [pickle](#)

Object serialization used by [shelve](#).

# marshal — Internal Python object serialization

---

This module contains functions that can read and write Python values in a binary format. The format is specific to Python, but independent of machine architecture issues (e.g., you can write a Python value to a file on a PC, transport the file to a Sun, and read it back there). Details of the format are undocumented on purpose; it may change between Python versions (although it rarely does). [1](#)

This is not a general “persistence” module. For general persistence and transfer of Python objects through RPC calls, see the modules [pickle](#) and [shelve](#). The [marshal](#) module exists mainly to support reading and writing the “pseudo-compiled” code for Python modules of `.pyc` files. Therefore, the Python maintainers reserve the right to modify the marshal format in backward incompatible ways should the need arise. If you’re serializing and de-serializing Python objects, use the [pickle](#) module instead – the performance is comparable, version independence is guaranteed, and pickle supports a substantially wider range of objects than marshal.

## Warning

The [marshal](#) module is not intended to be secure against erroneous or maliciously constructed data. Never unmarshal data received from an untrusted or unauthenticated source.

Not all Python object types are supported; in general, only objects whose value is independent from a particular invocation of Python can be written and read by this module. The following types are supported: booleans, integers, floating point numbers, complex numbers, strings, bytes, bytearrays, tuples, lists, sets, frozensets, dictionaries, and code objects, where it should be understood that tuples, lists, sets, frozensets and dictionaries are only supported as

long as the values contained therein are themselves supported. The singletons **None**, **Ellipsis** and **StopIteration** can also be marshalled and unmarshalled. For format *version* lower than 3, recursive lists, sets and dictionaries cannot be written (see below).

There are functions that read/write files as well as functions operating on bytes-like objects.

The module defines these functions:

`marshal.dump(value, file[, version])`

Write the value on the open file. The value must be a supported type. The file must be a writeable [binary file](#).

If the value has (or contains an object that has) an unsupported type, a **ValueError** exception is raised — but garbage data will also be written to the file. The object will not be properly read back by `load()`.

The *version* argument indicates the data format that `dump` should use (see below).

Raises an [auditing event](#) `marshal.dumps` with arguments `value`, `version`.

`marshal.load(file)`

Read one value from the open file and return it. If no valid value is read (e.g. because the data has a different Python version's incompatible marshal format), raise **EOFError**, **ValueError** or **TypeError**. The file must be a readable [binary file](#).

Raises an [auditing event](#) `marshal.load` with no arguments.

### Note

If an object containing an unsupported type was marshalled with `dump()`, `load()` will substitute `None` for the unmarshallable type.

*Changed in version 3.10:* This call used to raise a `code.__new__` audit event for each code object. Now it raises a single `marshal.load` event for the entire load operation.

`marshal.dumps(value[, version])`

Return the bytes object that would be written to a file by `dump(value, file)`. The value must be a supported type. Raise a **ValueError** exception if value has (or contains an object that has) an unsupported type.

The *version* argument indicates the data format that `dumps` should use (see below).

Raises an **auditing event** `marshal.dumps` with arguments `value, version`.

`marshal.loads(bytes)`

Convert the **bytes-like object** to a value. If no valid value is found, raise **EOFError**, **ValueError** or **TypeError**. Extra bytes in the input are ignored.

Raises an **auditing event** `marshal.loads` with argument `bytes`.

*Changed in version 3.10:* This call used to raise a `code.__new__` audit event for each code object. Now it raises a single `marshal.loads` event for the entire load operation.

In addition, the following constants are defined:

`marshal.version`

Indicates the format that the module uses. Version 0 is the historical format, version 1 shares interned strings and version 2 uses a binary format for floating point numbers. Version 3 adds support for object instantiation and recursion. The current version is 4.

## Footnotes

1

The name of this module stems from a bit of terminology used by the designers of Modula-3 (amongst others), who use the term “marshalling” for shipping of data around in a self-contained form. Strictly speaking, “to marshal” means to convert some data from internal to external form (in an RPC buffer for instance) and “unmarshalling” for the reverse process.

# dbm — Interfaces to Unix “databases”

**Source code:** [Lib/dbm/\\_init\\_.py](https://github.com/python/cpython/tree/3.11/Lib/dbm/_init_.py) [https://github.com/python/cpython/tree/3.11/Lib/dbm/\_init\_.py]

---

**dbm** is a generic interface to variants of the DBM database — **dbm.gnu** or **dbm.ndbm**. If none of these modules is installed, the slow-but-simple implementation in module **dbm.dumb** will be used. There is a [third party interface](https://www.jcea.es/programacion/pybsddb.htm) [https://www.jcea.es/programacion/pybsddb.htm] to the Oracle Berkeley DB.

*exception* dbm.error

A tuple containing the exceptions that can be raised by each of the supported modules, with a unique exception also named **dbm.error** as the first item — the latter is used when **dbm.error** is raised.

**dbm.whichdb(filename)**

This function attempts to guess which of the several simple database modules available — **dbm.gnu**, **dbm.ndbm** or **dbm.dumb** — should be used to open a given file.

Returns one of the following values: `None` if the file can't be opened because it's unreadable or doesn't exist; the empty string (`' '`) if the file's format can't be guessed; or a string containing the required module name, such as `'dbm.ndbm'` or `'dbm.gnu'`.

*Changed in version 3.11:* Accepts [path-like object](#) for filename.

**dbm.open(file, flag='r', mode=0o666)**

Open the database file *file* and return a corresponding object.

If the database file already exists, the `whichdb()` function is used to determine its type and the appropriate module is used; if it does not exist, the first module listed above that can be imported is used.

The optional *flag* argument can be:

### **Meaning**

---

**O**pen existing database for reading only (default)

---

**O**pen existing database for reading and writing

---

**O**pen database for reading and writing, creating it if it doesn't exist

---

**A**lways create a new, empty database, open for reading and writing

---

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666` (and will be modified by the prevailing `umask`).

The object returned by `open()` supports the same basic functionality as dictionaries; keys and their corresponding values can be stored, retrieved, and deleted, and the `in` operator and the `keys()` method are available, as well as `get()` and `setdefault()`.

*Changed in version 3.2:* `get()` and `setdefault()` are now available in all database modules.

*Changed in version 3.8:* Deleting a key from a read-only database raises database module specific error instead of `KeyError`.

*Changed in version 3.11:* Accepts `path-like object` for file.

Key and values are always stored as bytes. This means that when strings are used they are implicitly converted to the default encoding before being stored.

These objects also support being used in a `with` statement, which will automatically close them when done.

*Changed in version 3.4:* Added native support for the context

management protocol to the objects returned by `open()`.

The following example records some hostnames and a corresponding title, and then prints out the contents of the database:

```
import dbm

# Open database, creating it if necessary.
with dbm.open('cache', 'c') as db:

    # Record some values
    db[b'hello'] = b'there'
    db['www.python.org'] = 'Python Website'
    db['www.cnn.com'] = 'Cable News Network'

    # Note that the keys are considered bytes now.
    assert db[b'www.python.org'] == b'Python Website'
    # Notice how the value is now in bytes.
    assert db['www.cnn.com'] == b'Cable News Network'

    # Often-used methods of the dict interface work too.
    print(db.get('python.org', b'not present'))

    # Storing a non-string key or value will raise an exception
    # (likely a TypeError).
    db['www.yahoo.com'] = 4

# db is automatically closed when leaving the with statement
```

## See also

### Module `shelve`

Persistence module which stores non-string data.

The individual submodules are described in the following sections.

## `dbm.gnu` — GNU's reinterpretation of

# dbm

**Source code:** [Lib/dbm/gnu.py](https://github.com/python/cpython/tree/3.11/Lib/dbm/gnu.py) [https://github.com/python/cpython/tree/3.11/Lib/dbm/gnu.py]

---

This module is quite similar to the [dbm](#) module, but uses the GNU library `gdbm` instead to provide some additional functionality. Please note that the file formats created by [dbm.gnu](#) and [dbm.ndbm](#) are incompatible.

The [dbm.gnu](#) module provides an interface to the GNU DBM library. `dbm.gnu.gdbm` objects behave like mappings (dictionaries), except that keys and values are always converted to bytes before storing. Printing a `gdbm` object doesn't print the keys and values, and the `items()` and `values()` methods are not supported.

*exception* `dbm.gnu.error`

Raised on [dbm.gnu](#)-specific errors, such as I/O errors.

[KeyError](#) is raised for general mapping errors like specifying an incorrect key.

`dbm.gnu.open(filename[, flag[, mode]])`

Open a `gdbm` database and return a `gdbm` object. The *filename* argument is the name of the database file.

The optional *flag* argument can be:

## **Meaning**

---

Open existing database for reading only (default)

---

Open existing database for reading and writing

---

Open database for reading and writing, creating it if it doesn't exist

---

Always create a new, empty database, open for reading and writing

---

The following additional characters may be appended to the flag to control how the database is opened:

---

## Modifying

---

**Open** the database in fast mode. Writes to the database will not be synchronized.

---

**Synchronized** mode. This will cause changes to the database to be immediately written to the file.

---

**Do not** lock database.

---

Not all flags are valid for all versions of `gdbm`. The module constant `open_flags` is a string of supported flag characters. The exception `error` is raised if an invalid flag is specified.

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666`.

In addition to the dictionary-like methods, `gdbm` objects have the following methods:

*Changed in version 3.11:* Accepts [path-like object](#) for filename.

`gdbm.firstkey()`

It's possible to loop over every key in the database using this method and the [nextkey\(\)](#) method. The traversal is ordered by `gdbm`'s internal hash values, and won't be sorted by the key values. This method returns the starting key.

`gdbm.nextkey(key)`

Returns the key that follows *key* in the traversal. The following code prints every key in the database `db`, without having to create a list in memory that contains them all:

```
k = db.firstkey()
while k is not None:
    print(k)
    k = db.nextkey(k)
```

`gdbm.reorganize()`

If you have carried out a lot of deletions and would like to shrink the space used by the `gdbm` file, this routine will reorganize the database. `gdbm` objects will not shorten the length of a database file except by using this reorganization; otherwise, deleted file space will be kept and reused as new (key, value) pairs are added.

`gdbm.sync()`

When the database has been opened in fast mode, this method forces any unwritten data to be written to the disk.

`gdbm.close()`

Close the `gdbm` database.

## `dbm.ndbm` — Interface based on `ndbm`

**Source code:** [Lib/dbm/ndbm.py](https://github.com/python/cpython/tree/3.11/Lib/dbm/ndbm.py) [https://github.com/python/cpython/tree/3.11/Lib/dbm/ndbm.py]

---

The `dbm.ndbm` module provides an interface to the Unix “(n)dbm” library. Dbm objects behave like mappings (dictionaries), except that keys and values are always stored as bytes. Printing a `dbm` object doesn’t print the keys and values, and the `items()` and `values()` methods are not supported.

This module can be used with the “classic” `ndbm` interface or the GNU GDBM compatibility interface. On Unix, the **configure** script will attempt to locate the appropriate header file to simplify building this module.

*exception* `dbm.ndbm.error`

Raised on `dbm.ndbm`-specific errors, such as I/O errors.

**KeyError** is raised for general mapping errors like specifying an incorrect key.

`dbm.ndbm.library`

Name of the `ndbm` implementation library used.

`dbm.ndbm.open(filename[, flag[, mode]])`

Open a `dbm` database and return a `ndbm` object. The *filename* argument is the name of the database file (without the `.dir` or `.pag` extensions).

The optional *flag* argument must be one of these values:

#### **Meaning**

---

**O**pen existing database for reading only (default)

---

**O**pen existing database for reading and writing

---

**O**pen database for reading and writing, creating it if it doesn't exist

---

**A**lways create a new, empty database, open for reading and writing

---

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666` (and will be modified by the prevailing `umask`).

In addition to the dictionary-like methods, `ndbm` objects provide the following method:

*Changed in version 3.11:* Accepts [path-like object](#) for *filename*.

`ndbm.close()`

Close the `ndbm` database.

## **`dbm.dumb` — Portable DBM implementation**

**Source code:** [Lib/dbm/dumb.py](https://github.com/python/cpython/tree/3.11/Lib/dbm/dumb.py) [https://github.com/python/cpython/tree/3.11/Lib/dbm/dumb.py]

### **Note**

The `dbm.dumb` module is intended as a last resort fallback for the `dbm` module when a more robust module is not available.

The `dbm.dumb` module is not written for speed and is not nearly as heavily used as the other database modules.

---

The `dbm.dumb` module provides a persistent dictionary-like interface which is written entirely in Python. Unlike other modules such as `dbm.gnu` no external library is required. As with other persistent mappings, the keys and values are always stored as bytes.

The module defines the following:

*exception* `dbm.dumb.error`

Raised on `dbm.dumb`-specific errors, such as I/O errors.

`KeyError` is raised for general mapping errors like specifying an incorrect key.

`dbm.dumb.open(filename[, flag[, mode]])`

Open a `dumbdbm` database and return a `dumbdbm` object.

The *filename* argument is the basename of the database file (without any specific extensions). When a `dumbdbm` database is created, files with `.dat` and `.dir` extensions are created.

The optional *flag* argument can be:

### **Meaning**

---

Open existing database for reading only (default)

---

Open existing database for reading and writing

---

Open database for reading and writing, creating it if it doesn't exist

---

Always create a new, empty database, open for reading and writing

---

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666` (and will be modified by the prevailing `umask`).

### **Warning**

It is possible to crash the Python interpreter when loading a database with a sufficiently large/complex entry due to

stack depth limitations in Python's AST compiler.

*Changed in version 3.5:* `open()` always creates a new database when the flag has the value `'n'`.

*Changed in version 3.8:* A database opened with flags `'r'` is now read-only. Opening with flags `'r'` and `'w'` no longer creates a database if it does not exist.

*Changed in version 3.11:* Accepts [path-like object](#) for filename.

In addition to the methods provided by the [collections.abc.MutableMapping](#) class, `dumbdbm` objects provide the following methods:

`dumbdbm.sync()`

Synchronize the on-disk directory and data files. This method is called by the `Shelve.sync()` method.

`dumbdbm.close()`

Close the `dumbdbm` database.

# sqlite3 — DB-API 2.0 interface for SQLite databases

**Source code:** [Lib/sqlite3/](https://github.com/python/cpython/tree/3.11/Lib/sqlite3/) [https://github.com/python/cpython/tree/3.11/Lib/sqlite3/]

SQLite is a C library that provides a lightweight disk-based database that doesn't require a separate server process and allows accessing the database using a nonstandard variant of the SQL query language. Some applications can use SQLite for internal data storage. It's also possible to prototype an application using SQLite and then port the code to a larger database such as PostgreSQL or Oracle.

The **sqlite3** module was written by Gerhard Häring. It provides an SQL interface compliant with the DB-API 2.0 specification described by [PEP 249](https://peps.python.org/pep-0249/) [https://peps.python.org/pep-0249/], and requires SQLite 3.7.15 or newer.

This document includes four main sections:

- [Tutorial](#) teaches how to use the **sqlite3** module.
- [Reference](#) describes the classes and functions this module defines.
- [How-to guides](#) details how to handle specific tasks.
- [Explanation](#) provides in-depth background on transaction control.

## PEP 249 [https://peps.python.org/pep-0249/] - Database API Specification 2.0

PEP written by Marc-André Lemburg.

# Tutorial

In this tutorial, you will create a database of Monty Python movies using basic **sqlite3** functionality. It assumes a fundamental understanding of database concepts, including **cursors** [https://en.wikipedia.org/wiki/Cursor\_(databases)] and **transactions** [https://en.wikipedia.org/wiki/Database\_transaction].

First, we need to create a new database and open a database connection to allow **sqlite3** to work with it. Call **sqlite3.connect()** to create a connection to the database `tutorial.db` in the current working directory, implicitly creating it if it does not exist:

```
import sqlite3
con = sqlite3.connect("tutorial.db")
```

The returned **Connection** object `con` represents the connection to the on-disk database.

In order to execute SQL statements and fetch results from SQL queries, we will need to use a database cursor. Call **con.cursor()** to create the **Cursor**:

```
cur = con.cursor()
```

Now that we've got a database connection and a cursor, we can create a database table `movie` with columns for title, release year, and review score. For simplicity, we can just use column names in the table declaration – thanks to the **flexible typing** [https://www.sqlite.org/flextypegood.html] feature of SQLite, specifying the data types is optional. Execute the `CREATE TABLE` statement by calling **cur.execute(...)**:

```
cur.execute("CREATE TABLE movie(title, year, score)")
```

We can verify that the new table has been created by querying the `sqlite_master` table built-in to SQLite, which should now contain an entry for the `movie` table definition (see [The Schema Table](https://www.sqlite.org/schematab.html) [https://www.sqlite.org/schematab.html] for details). Execute that query by calling `cur.execute(...)`, assign the result to `res`, and call `res.fetchone()` to fetch the resulting row:

```
>>> res = cur.execute("SELECT name FROM sqlite_master")
>>> res.fetchone()
('movie',)
```

We can see that the table has been created, as the query returns a **tuple** containing the table's name. If we query `sqlite_master` for a non-existent table `spam`, `res.fetchone()` will return `None`:

```
>>> res = cur.execute("SELECT name FROM sqlite_master WHERE name='spam'")
>>> res.fetchone() is None
True
```

Now, add two rows of data supplied as SQL literals by executing an `INSERT` statement, once again by calling `cur.execute(...)`:

```
cur.execute("""
    INSERT INTO movie VALUES
        ('Monty Python and the Holy Grail', 1975, 8.2),
        ('And Now for Something Completely Different', 1971, 8.5)
""")
```

The `INSERT` statement implicitly opens a transaction, which needs to be committed before changes are saved in the database (see [Transaction control](#) for details). Call `con.commit()` on the connection object to commit the transaction:

```
con.commit()
```

We can verify that the data was inserted correctly by executing a `SELECT` query. Use the now-familiar `cur.execute(...)` to assign the result to `res`, and call `res.fetchall()` to return all

resulting rows:

```
>>> res = cur.execute("SELECT score FROM movie")
>>> res.fetchall()
[(8.2,), (7.5,)]
```

The result is a **list** of two **tuples**, one per row, each containing that row's score value.

Now, insert three more rows by calling **cur.executemany(...)**:

```
data = [
    ("Monty Python Live at the Hollywood Bowl", 1982, 7.5),
    ("Monty Python's The Meaning of Life", 1983, 7.5),
    ("Monty Python's Life of Brian", 1979, 8.0),
]
cur.executemany("INSERT INTO movie VALUES(?, ?, ?)", data)
con.commit() # Remember to commit the transaction after
```

Notice that `?` placeholders are used to bind data to the query. Always use placeholders instead of **string formatting** to bind Python values to SQL statements, to avoid **SQL injection attacks** [[https://en.wikipedia.org/wiki/SQL\\_injection](https://en.wikipedia.org/wiki/SQL_injection)] (see **How to use placeholders to bind values in SQL queries** for more details).

We can verify that the new rows were inserted by executing a **SELECT** query, this time iterating over the results of the query:

```
>>> for row in cur.execute("SELECT year, title FROM movie"):
...     print(row)
(1971, 'And Now for Something Completely Different')
(1975, 'Monty Python and the Holy Grail')
(1979, 'Monty Python's Life of Brian')
(1982, 'Monty Python Live at the Hollywood Bowl')
(1983, 'Monty Python's The Meaning of Life')
```

Each row is a two-item **tuple** of (year, title), matching the columns selected in the query.

Finally, verify that the database has been written to disk by calling **con.close()** to close the existing connection, opening a new one,

creating a new cursor, then querying the database:

```
>>> con.close()
>>> new_con = sqlite3.connect("tutorial.db")
>>> new_cur = new_con.cursor()
>>> res = new_cur.execute("SELECT title, year FROM movie")
>>> title, year = res.fetchone()
>>> print(f'The highest scoring Monty Python movie is {title}, {year}')
The highest scoring Monty Python movie is 'Monty Python and the Holy Grail', 1975
```

You've now created an SQLite database using the **sqlite3** module, inserted data and retrieved values from it in multiple ways.

# Reference

## Module functions

```
sqlite3.connect(database, timeout=5.0, detect_types=0,
isolation_level='DEFERRED', check_same_thread=True,
factory=sqlite3.Connection, cached_statements=128, uri=False)
```

Open a connection to an SQLite database.

## Parameters

- **database** (*path-like object*) – The path to the database file to be opened. Pass `":memory:"` to open a connection to a database that is in RAM instead of on disk.
- **timeout** (*float*) – How many seconds the connection should wait before raising an **OperationalError** when a table is locked. If another connection opens a transaction to modify a table, that table will be locked until the transaction is committed. Default five seconds.
- **detect\_types** (*int*) – Control whether and how data types not *natively supported by SQLite* are looked up to be converted to Python types, using the converters registered with **register\_converter()**. Set it to any combination (using `|`, bitwise or) of **PARSE\_DECLTYPES** and **PARSE\_COLNAMES** to enable this. Column names takes precedence over declared types if both flags are set. Types cannot be detected for generated fields (for example `max(data)`), even when the *detect\_types* parameter is set; **str** will be returned instead. By default (0), type detection is disabled.
- **isolation\_level** (*str | None*) – The **isolation\_level** of the connection, controlling whether and how transactions are implicitly opened. Can be `"DEFERRED"` (default), `"EXCLUSIVE"` or `"IMMEDIATE"`; or `None` to disable opening transactions implicitly. See [Transaction control](#) for more.
- **check\_same\_thread** (*bool*) – If `True`

(default), **ProgrammingError** will be raised if the database connection is used by a thread other than the one that created it. If `False`, the connection may be accessed in multiple threads; write operations may need to be serialized by the user to avoid data corruption. See **threadsafety** for more information.

- **factory** (**Connection**) – A custom subclass of **Connection** to create the connection with, if not the default **Connection** class.
- **cached\_statements** (**int**) – The number of statements that **sqlite3** should internally cache for this connection, to avoid parsing overhead. By default, 128 statements.
- **uri** (**bool**) – If set to `True`, *database* is interpreted as a URI with a file path and an optional query string. The scheme part *must* be `"file:"`, and the path can be relative or absolute. The query string allows passing parameters to SQLite, enabling various [How to work with SQLite URIs](#).

## Return type

**Connection**

Raises an **auditing event** `sqlite3.connect` with argument `database`.

Raises an **auditing event** `sqlite3.connect/handle` with argument `connection_handle`.

*New in version 3.4:* The `uri` parameter.

*Changed in version 3.7:* `database` can now also be a **path-like object**, not only a string.

*New in version 3.10:* The `sqlite3.connect/handle` auditing event.

`sqlite3.complete_statement(statement)`

Return `True` if the string *statement* appears to contain one or more complete SQL statements. No syntactic verification or parsing of any kind is performed, other than checking that there are no unclosed string literals and the statement is terminated by a semicolon.

For example:

```
>>> sqlite3.complete_statement("SELECT foo FROM bar")
True
>>> sqlite3.complete_statement("SELECT foo")
False
```

This function may be useful during command-line input to determine if the entered text seems to form a complete SQL statement, or if additional input is needed before calling `execute()`.

`sqlite3.enable_callback_tracebacks(flag, /)`

Enable or disable callback tracebacks. By default you will not get any tracebacks in user-defined functions, aggregates, converters, authorizer callbacks etc. If you want to debug them, you can call this function with *flag* set to `True`. Afterwards, you will get tracebacks from callbacks on `sys.stderr`. Use `False` to disable the feature again.

Register an `unraisable hook handler` for an improved debug experience:

```
>>> sqlite3.enable_callback_tracebacks(True)
>>> con = sqlite3.connect(":memory:")
>>> def evil_trace(stmt):
...     5/0
>>> con.set_trace_callback(evil_trace)
>>> def debug(unraisable):
```

```

...     print(f"{unraisable.exc_value!r} in callbac
...     print(f"Error message: {unraisable.err_msg}
>>> import sys
>>> sys.unraisablehook = debug
>>> cur = con.execute("SELECT 1")
ZeroDivisionError('division by zero') in callback e
Error message: None

```

`sqlite3.register_adapter(type, adapter, /)`

Register an *adapter* [callable](#) to adapt the Python type *type* into an SQLite type. The adapter is called with a Python object of type *type* as its sole argument, and must return a value of a [type that SQLite natively understands](#).

`sqlite3.register_converter(typename, converter, /)`

Register the *converter* [callable](#) to convert SQLite objects of type *typename* into a Python object of a specific type. The converter is invoked for all SQLite values of type *typename*; it is passed a [bytes](#) object and should return an object of the desired Python type. Consult the parameter *detect\_types* of [connect \(\)](#) for information regarding how type detection works.

Note: *typename* and the name of the type in your query are matched case-insensitively.

## Module constants

`sqlite3.PARSE_COLNAMES`

Pass this flag value to the *detect\_types* parameter of [connect \(\)](#) to look up a converter function by using the type name, parsed from the query column name, as the converter dictionary key. The type name must be wrapped in square brackets (`[]`).

```
SELECT p as "p [point]" FROM test;  ! will look up
```

This flag may be combined with [PARSE\\_DECLTYPES](#) using

the `|` (bitwise or) operator.

### sqlite3.PARSE\_DECLTYPES

Pass this flag value to the *detect\_types* parameter of `connect()` to look up a converter function using the declared types for each column. The types are declared when the database table is created. `sqlite3` will look up a converter function using the first word of the declared type as the converter dictionary key. For example:

```
CREATE TABLE test(  
    i integer primary key,    ! will look up a convert  
    p point,                  ! will look up a convert  
    n number(10)              ! will look up a convert  
)
```

This flag may be combined with `PARSE_COLNAMES` using the `|` (bitwise or) operator.

### sqlite3.SQLITE\_OK

### sqlite3.SQLITE\_DENY

### sqlite3.SQLITE\_IGNORE

Flags that should be returned by the *authorizer\_callback callable* passed to `Connection.set_authorizer()`, to indicate whether:

- Access is allowed (`SQLITE_OK`),
- The SQL statement should be aborted with an error (`SQLITE_DENY`)
- The column should be treated as a `NULL` value (`SQLITE_IGNORE`)

### sqlite3.apilevel

String constant stating the supported DB-API level. Required by the DB-API. Hard-coded to `"2.0"`.

### sqlite3.paramstyle

String constant stating the type of parameter marker formatting expected by the `sqlite3` module. Required by

the DB-API. Hard-coded to "qmark".

### Note

The `named` DB-API parameter style is also supported.

`sqlite3.sqlite_version`

Version number of the runtime SQLite library as a **string**.

`sqlite3.sqlite_version_info`

Version number of the runtime SQLite library as a **tuple of integers**.

`sqlite3.threadafety`

Integer constant required by the DB-API 2.0, stating the level of thread safety the **sqlite3** module supports. This attribute is set based on the default **threading mode** [<https://sqlite.org/threadsafe.html>] the underlying SQLite library is compiled with. The SQLite threading modes are:

1. **Single-thread:** In this mode, all mutexes are disabled and SQLite is unsafe to use in more than a single thread at once.
2. **Multi-thread:** In this mode, SQLite can be safely used by multiple threads provided that no single database connection is used simultaneously in two or more threads.
3. **Serialized:** In serialized mode, SQLite can be safely used by multiple threads with no restriction.

The mappings from SQLite threading modes to DB-API 2.0 threadafety levels are as follows:

**DB-API 2.0 threading mode**

**Single-thread** not share the module

---

~~Threaded~~ may share the module, but not connections

~~Serialized~~ may share the module, connections and cursors

---

*Changed in version 3.11:* Set *threadsafety* dynamically instead of hard-coding it to 1.

sqlite3.version

Version number of this module as a **string**. This is not the version of the SQLite library.

sqlite3.version\_info

Version number of this module as a **tuple** of **integers**. This is not the version of the SQLite library.

## Connection objects

*class* sqlite3.Connection

Each open SQLite database is represented by a `Connection` object, which is created using `sqlite3.connect()`. Their main purpose is creating **Cursor** objects, and **Transaction control**.

### See also

- [How to use connection shortcut methods](#)
- [How to use the connection context manager](#)

An SQLite database connection has the following attributes and methods:

`cursor(factory=Cursor)`

Create and return a **Cursor** object. The cursor method accepts a single optional parameter *factory*. If supplied, this must be a **callable** returning an instance of **Cursor** or its subclasses.

`blobopen(table, column, row, /, *, readonly=False, name='main')`

Open a **Blob** handle to an existing BLOB.

### Parameters

- **table** (*str*) – The name of the table where the blob is located.
- **column** (*str*) – The name of the column where the blob is located.
- **row** (*str*) – The name of the row where the blob is located.
- **readonly** (*bool*) – Set to `True` if the blob should be opened without write permissions. Defaults to `False`.
- **name** (*str*) – The name of the database where the blob is located. Defaults to `"main"`.

### Raises

**OperationalError** – When trying to open a blob in a `WITHOUT ROWID` table.

### Return type

**Blob**

### Note

The blob size cannot be changed using the **Blob** class. Use the SQL function `zeroblob` to create a blob with a fixed size.

*New in version 3.11.*

### `commit()`

Commit any pending transaction to the database. If there is no open transaction, this method is a no-op.

### `rollback()`

Roll back to the start of any pending transaction. If there is no open transaction, this method is a no-op.

`close()`

Close the database connection. Any pending transaction is not committed implicitly; make sure to `commit()` before closing to avoid losing pending changes.

`execute(sql, parameters=(), /)`

Create a new `Cursor` object and call `execute()` on it with the given `sql` and `parameters`. Return the new cursor object.

`executemany(sql, parameters, /)`

Create a new `Cursor` object and call `executemany()` on it with the given `sql` and `parameters`. Return the new cursor object.

`executescript(sql_script, /)`

Create a new `Cursor` object and call `executescript()` on it with the given `sql_script`. Return the new cursor object.

`create_function(name, narg, func, *, deterministic=False)`

Create or remove a user-defined SQL function.

### Parameters

- **name** (*str*) – The name of the SQL function.
- **narg** (*int*) – The number of arguments the SQL function can accept. If `-1`, it may take any number of arguments.
- **func** (*callable* | `None`) – A *callable* that is called when the SQL function is invoked. The callable must return a *type natively supported by SQLite*. Set to `None` to remove an existing SQL function.

- **deterministic** (*bool*) – If `True`, the created SQL function is marked as **deterministic** [<https://sqlite.org/deterministic.html>], which allows SQLite to perform additional optimizations.

## Raises

**NotSupportedError** – If *deterministic* is used with SQLite versions older than 3.8.3.

*New in version 3.8:* The *deterministic* parameter.

## Example:

```
>>> import hashlib
>>> def md5sum(t):
...     return hashlib.md5(t).hexdigest()
>>> con = sqlite3.connect(":memory:")
>>> con.create_function("md5", 1, md5sum)
>>> for row in con.execute("SELECT md5(?)", (b'
...     print(row)
('acbd18db4cc2f85cedef654fccc4a4d8',)
```

`create_aggregate(name, /, n_arg, aggregate_class)`

Create or remove a user-defined SQL aggregate function.

## Parameters

- **name** (*str*) – The name of the SQL aggregate function.
- **n\_arg** (*int*) – The number of arguments the SQL aggregate function can accept. If `-1`, it may take any number of arguments.
- **aggregate\_class** (*class* | `None`) – A class must implement the following methods:

- `step()`: Add a row to the aggregate.
- `finalize()`: Return the final result of the aggregate as a type natively supported by SQLite.

The number of arguments that the `step()` method must accept is controlled by *n\_arg*.

Set to `None` to remove an existing SQL aggregate function.

Example:

```
class MySum:
    def __init__(self):
        self.count = 0

    def step(self, value):
        self.count += value

    def finalize(self):
        return self.count

con = sqlite3.connect(":memory:")
con.create_aggregate("mysum", 1, MySum)
cur = con.execute("CREATE TABLE test(i)")
cur.execute("INSERT INTO test(i) VALUES(1)")
cur.execute("INSERT INTO test(i) VALUES(2)")
cur.execute("SELECT mysum(i) FROM test")
print(cur.fetchone()[0])

con.close()
```

`create_window_function(name, num_params, aggregate_class, /)`

Create or remove a user-defined aggregate window function.

### Parameters

- **name** (*str*) – The name of the SQL aggregate window function to create or remove.
- **num\_params** (*int*) – The number of arguments the SQL aggregate window function can accept. If -1, it may take any number of arguments.
- **aggregate\_class** (*class* | None) – A class that must implement the following methods:
  - `step()`: Add a row to the current window.
  - `value()`: Return the current value of the aggregate.
  - `inverse()`: Remove a row from the current window.
  - `finalize()`: Return the final result of the aggregate as a [type natively supported by SQLite](#).

The number of arguments that the `step()` and `value()` methods must accept is controlled by *num\_params*. Set to `None` to remove an existing SQL aggregate window function.

## Raises

**NotSupportedError** – If used with a version of SQLite older than 3.25.0, which does not support aggregate window functions.

*New in version 3.11.*

Example:

```
# Example taken from https://www.sqlite.org/win
class WindowSumInt:
```

```

def __init__(self):
    self.count = 0

def step(self, value):
    """Add a row to the current window."""
    self.count += value

def value(self):
    """Return the current value of the aggregate function
    return self.count

def inverse(self, value):
    """Remove a row from the current window
    self.count -= value

def finalize(self):
    """Return the final value of the aggregate function
    Any clean-up actions should be placed here
    """
    return self.count

```

```

con = sqlite3.connect(":memory:")
cur = con.execute("CREATE TABLE test(x, y)")
values = [
    ("a", 4),
    ("b", 5),
    ("c", 3),
    ("d", 8),
    ("e", 1),
]
cur.executemany("INSERT INTO test VALUES(?, ?)")
con.create_window_function("sumint", 1, WindowSum)
cur.execute("""
    SELECT x, sumint(y) OVER (
        ORDER BY x ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING
    ) AS sum_y

```

```

        FROM test ORDER BY x
    """
    print(cur.fetchall())

```

`create_collation(name, callable)`

Create a collation named *name* using the collating function *callable*. *callable* is passed two **string** arguments, and it should return an **integer**:

- 1 if the first is ordered higher than the second
- -1 if the first is ordered lower than the second
- 0 if they are ordered equal

The following example shows a reverse sorting collation:

```

def collate_reverse(string1, string2):
    if string1 == string2:
        return 0
    elif string1 < string2:
        return 1
    else:
        return -1

```

```

con = sqlite3.connect(":memory:")
con.create_collation("reverse", collate_reverse)

```

```

cur = con.execute("CREATE TABLE test(x)")
cur.executemany("INSERT INTO test(x) VALUES(?)")
cur.execute("SELECT x FROM test ORDER BY x COLLATE reverse")
for row in cur:
    print(row)
con.close()

```

Remove a collation function by setting *callable* to `None`.

**Changed in version 3.11:** The collation name can contain any Unicode character. Earlier, only ASCII characters

were allowed.

## `interrupt()`

Call this method from a different thread to abort any queries that might be executing on the connection. Aborted queries will raise an **`OperationalError`**.

## `set_authorizer(authorizer_callback)`

Register callable *authorizer\_callback* to be invoked for each attempt to access a column of a table in the database. The callback should return one of **`SQLITE_OK`**, **`SQLITE_DENY`**, or **`SQLITE_IGNORE`** to signal how access to the column should be handled by the underlying SQLite library.

The first argument to the callback signifies what kind of operation is to be authorized. The second and third argument will be arguments or `None` depending on the first argument. The 4th argument is the name of the database (“main”, “temp”, etc.) if applicable. The 5th argument is the name of the inner-most trigger or view that is responsible for the access attempt or `None` if this access attempt is directly from input SQL code.

Please consult the SQLite documentation about the possible values for the first argument and the meaning of the second and third argument depending on the first one. All necessary constants are available in the **`sqlite3`** module.

Passing `None` as *authorizer\_callback* will disable the authorizer.

*Changed in version 3.11:* Added support for disabling the authorizer using `None`.

## `set_progress_handler(progress_handler, n)`

Register callable *progress\_handler* to be invoked for every *n* instructions of the SQLite virtual machine. This

is useful if you want to get called from SQLite during long-running operations, for example to update a GUI.

If you want to clear any previously installed progress handler, call the method with `None` for *progress\_handler*.

Returning a non-zero value from the handler function will terminate the currently executing query and cause it to raise an **OperationalError** exception.

`set_trace_callback(trace_callback)`

Register **callable** *trace\_callback* to be invoked for each SQL statement that is actually executed by the SQLite backend.

The only argument passed to the callback is the statement (as **str**) that is being executed. The return value of the callback is ignored. Note that the backend does not only run statements passed to the **Cursor.execute()** methods. Other sources include the **transaction management** of the **sqlite3** module and the execution of triggers defined in the current database.

Passing `None` as *trace\_callback* will disable the trace callback.

### Note

Exceptions raised in the trace callback are not propagated. As a development and debugging aid, use **enable\_callback\_tracebacks()** to enable printing tracebacks from exceptions raised in the trace callback.

*New in version 3.3.*

`enable_load_extension(enabled, /)`

Enable the SQLite engine to load SQLite extensions from shared libraries if *enabled* is `True`; else, disallow loading SQLite extensions. SQLite extensions can define new functions, aggregates or whole new virtual table implementations. One well-known extension is the fulltext-search extension distributed with SQLite.

### Note

The `sqlite3` module is not built with loadable extension support by default, because some platforms (notably macOS) have SQLite libraries which are compiled without this feature. To get loadable extension support, you must pass the `--enable-loadable-sqlite-extensions` option to `configure`.

Raises an [auditing event](#)

`sqlite3.enable_load_extension` with arguments `connection`, `enabled`.

*New in version 3.2.*

*Changed in version 3.10:* Added the

`sqlite3.enable_load_extension` auditing event.

```
con.enable_load_extension(True)

# Load the fulltext search extension
con.execute("select load_extension('./fts3.so')")

# alternatively you can load the extension using
# con.load_extension("./fts3.so")

# disable extension loading again
con.enable_load_extension(False)

# example from SQLite wiki
con.execute("CREATE VIRTUAL TABLE recipe USING
con.executescript("""
```

```

        INSERT INTO recipe (name, ingredients) VALUES
        INSERT INTO recipe (name, ingredients) VALUES
        INSERT INTO recipe (name, ingredients) VALUES
        INSERT INTO recipe (name, ingredients) VALUES
        """)
for row in con.execute("SELECT rowid, name, ingredients"):
    print(row)

con.close()

```

### `load_extension(path, /)`

Load an SQLite extension from a shared library located at *path*. Enable extension loading with [enable\\_load\\_extension\(\)](#) before calling this method.

Raises an [auditing event](#) `sqlite3.load_extension` with arguments `connection`, `path`.

*New in version 3.2.*

*Changed in version 3.10:* Added the `sqlite3.load_extension` auditing event.

### `iterdump()`

Return an [iterator](#) to dump the database as SQL source code. Useful when saving an in-memory database for later restoration. Similar to the `.dump` command in the **sqlite3** shell.

Example:

```

# Convert file example.db to SQL dump file dump.sql
con = sqlite3.connect('example.db')
with open('dump.sql', 'w') as f:
    for line in con.iterdump():
        f.write('%s\n' % line)
con.close()

```

```
backup(target, *, pages = - 1, progress = None, name = 'main',  
sleep = 0.250)
```

Create a backup of an SQLite database.

Works even if the database is being accessed by other clients or concurrently by the same connection.

### Parameters

- **target** (*Connection*) – The database connection to save the backup to.
- **pages** (*int*) – The number of pages to copy at a time. If equal to or less than 0, the entire database is copied in a single step. Defaults to -1.
- **progress** (*callback* | None) – If set to a *callable*, it is invoked with three integer arguments for every backup iteration: the *status* of the last iteration, the *remaining* number of pages still to be copied, and the *total* number of pages. Defaults to None.
- **name** (*str*) – The name of the database to back up. Either "main" (the default) for the main database, "temp" for the temporary database, or the name of a custom database as attached using the ATTACH DATABASE SQL statement.
- **sleep** (*float*) – The number of seconds to sleep between successive attempts to back up remaining pages.

Example 1, copy an existing database into another:

```
def progress(status, remaining, total):
```

```

        print(f'Copied {total-remaining} of {total}')

src = sqlite3.connect('example.db')
dst = sqlite3.connect('backup.db')
with dst:
    src.backup(dst, pages=1, progress=progress)
dst.close()
src.close()

```

Example 2, copy an existing database into a transient copy:

```

src = sqlite3.connect('example.db')
dst = sqlite3.connect(':memory:')
src.backup(dst)

```

*New in version 3.7.*

`getlimit(category, /)`

Get a connection runtime limit.

### Parameters

**category** (*int*) – The [SQLite limit category](https://www.sqlite.org/c3ref/c_limit_attached.html) [https://www.sqlite.org/c3ref/c\_limit\_attached.html] to be queried.

### Return type

*int*

### Raises

**ProgrammingError** – If *category* is not recognised by the underlying SQLite library.

Example, query the maximum length of an SQL statement for [Connection](#) `con` (the default is 10000000000):

```

>>> con.getlimit(sqlite3.SQLITE_LIMIT_SQL_LENGTH)
10000000000

```

*New in version 3.11.*

`setlimit(category, limit, /)`

Set a connection runtime limit. Attempts to increase a limit above its hard upper bound are silently truncated to the hard upper bound. Regardless of whether or not the limit was changed, the prior value of the limit is returned.

### Parameters

- **category** (*int*) – The [SQLite limit category](https://www.sqlite.org/c3ref/c_limit_attached.html) [https://www.sqlite.org/c3ref/c\_limit\_attached.html] to be set.
- **limit** (*int*) – The value of the new limit. If negative, the current limit is unchanged.

### Return type

[int](#)

### Raises

[ProgrammingError](#) – If *category* is not recognised by the underlying SQLite library.

Example, limit the number of attached databases to 1 for [Connection](#) `con` (the default limit is 10):

```
>>> con.setlimit(sqlite3.SQLITE_LIMIT_ATTACHED, 10)
>>> con.getlimit(sqlite3.SQLITE_LIMIT_ATTACHED)
1
```

*New in version 3.11.*

`serialize(*, name='main')`

Serialize a database into a [bytes](#) object. For an ordinary on-disk database file, the serialization is just a copy of the disk file. For an in-memory database or a “temp” database, the serialization is the same sequence of bytes which would be written to disk if that database were backed up to disk.

## Parameters

**name** (*str*) – The database name to be serialized. Defaults to "main".

## Return type

*bytes*

## Note

This method is only available if the underlying SQLite library has the serialize API.

*New in version 3.11.*

`deserialize(data, /, *, name='main')`

Deserialize a **serialized** database into a **Connection**. This method causes the database connection to disconnect from database *name*, and reopen *name* as an in-memory database based on the serialization contained in *data*.

## Parameters

- **data** (*bytes*) – A serialized database.
- **name** (*str*) – The database name to deserialize into. Defaults to "main".

## Raises

- **OperationalError** – If the database connection is currently involved in a read transaction or a backup operation.
- **DatabaseError** – If *data* does not contain a valid SQLite database.
- **OverflowError** – If `len(data)` is larger than  $2^{63} - 1$ .

## Note

This method is only available if the underlying

SQLite library has the `deserialize` API.

*New in version 3.11.*

### `in_transaction`

This read-only attribute corresponds to the low-level SQLite [autocommit mode](https://www.sqlite.org/lang_transaction.html#implicit_versus_explicit_transactions) [https://www.sqlite.org/lang\_transaction.html#implicit\_versus\_explicit\_transactions].

`True` if a transaction is active (there are uncommitted changes), `False` otherwise.

*New in version 3.2.*

### `isolation_level`

This attribute controls the [transaction handling](https://www.sqlite.org/lang_transaction.html#deferred_immediate_and_exclusive_transactions) performed by `sqlite3`. If set to `None`, transactions are never implicitly opened. If set to one of `"DEFERRED"`, `"IMMEDIATE"`, or `"EXCLUSIVE"`, corresponding to the underlying [SQLite transaction behaviour](https://www.sqlite.org/lang_transaction.html#deferred_immediate_and_exclusive_transactions) [https://www.sqlite.org/lang\_transaction.html#deferred\_immediate\_and\_exclusive\_transactions], implicit [transaction management](https://www.sqlite.org/lang_transaction.html#deferred_immediate_and_exclusive_transactions) is performed.

If not overridden by the `isolation_level` parameter of `connect()`, the default is `" "`, which is an alias for `"DEFERRED"`.

### `row_factory`

The initial [row\\_factory](#) for `Cursor` objects created from this connection. Assigning to this attribute does not affect the `row_factory` of existing cursors belonging to this connection, only new ones. Is `None` by default, meaning each row is returned as a [tuple](#).

See [How to create and use row factories](#) for more details.

### `text_factory`

A [callable](#) that accepts a [bytes](#) parameter and returns a text representation of it. The callable is invoked for SQLite values with the `TEXT` data type. By default, this attribute is set to [str](#). If you want to return `bytes` instead, set `text_factory` to `bytes`.

Example:

```
con = sqlite3.connect(":memory:")
cur = con.cursor()
```

```
AUSTRIA = "Österreich"
```

```
# by default, rows are returned as str
cur.execute("SELECT ?", (AUSTRIA,))
row = cur.fetchone()
assert row[0] == AUSTRIA
```

```
# but we can make sqlite3 always return bytestrings
con.text_factory = bytes
cur.execute("SELECT ?", (AUSTRIA,))
row = cur.fetchone()
assert type(row[0]) is bytes
# the bytestrings will be encoded in UTF-8, unless you specify
# database ...
assert row[0] == AUSTRIA.encode("utf-8")
```

```
# we can also implement a custom text_factory
# here we implement one that appends "foo" to a string
con.text_factory = lambda x: x.decode("utf-8") + "foo"
cur.execute("SELECT ?", ("bar",))
row = cur.fetchone()
assert row[0] == "barfoo"
```

```
con.close()
```

## `total_changes`

Return the total number of database rows that have been modified, inserted, or deleted since the database

connection was opened.

## Cursor objects

A `Cursor` object represents a [database cursor](https://en.wikipedia.org/wiki/Cursor_(databases)) [https://en.wikipedia.org/wiki/Cursor\_(databases)] which is used to execute SQL statements, and manage the context of a fetch operation. Cursors are created using `Connection.cursor()`, or by using any of the [connection shortcut methods](#).

Cursor objects are [iterators](#), meaning that if you `execute()` a `SELECT` query, you can simply iterate over the cursor to fetch the resulting rows:

```
for row in cur.execute("SELECT t FROM data"):
    print(row)
```

`class sqlite3.Cursor`

A `Cursor` instance has the following attributes and methods.

`execute(sql, parameters = (), /)`

Execute SQL a single SQL statement, optionally binding Python values using [placeholders](#).

### Parameters

- `sql` ([str](#)) – A single SQL statement.
- `parameters` ([dict](#) | [sequence](#)) – Python values to bind to placeholders in `sql`. A `dict` if named placeholders are used. A sequence if unnamed placeholders are used. See [How to use placeholders to bind values in SQL queries](#).

### Raises

[ProgrammingError](#) – If `sql`

contains more than one SQL statement.

If `isolation_level` is not `None`, `sql` is an `INSERT`, `UPDATE`, `DELETE`, or `REPLACE` statement, and there is no open transaction, a transaction is implicitly opened before executing `sql`.

Use `executescript()` to execute multiple SQL statements.

`executemany(sql, parameters, /)`

For every item in `parameters`, repeatedly execute the `parameterized` DML SQL statement `sql`.

Uses the same implicit transaction handling as `execute()`.

### Parameters

- `sql (str)` – A single SQL DML statement.
- `parameters (iterable)` – An iterable of parameters to bind with the placeholders in `sql`. See [How to use placeholders to bind values in SQL queries](#).

### Raises

**ProgrammingError** – If `sql` contains more than one SQL statement, or is not a DML statement.

Example:

```
rows = [
    ("row1",),
    ("row2",),
]
# cur is an sqlite3.Cursor object
cur.executemany("INSERT INTO data VALUES(?)", rows)
```

## Note

Any resulting rows are discarded, including DML statements with **RETURNING clauses** [[https://www.sqlite.org/lang\\_returning.html](https://www.sqlite.org/lang_returning.html)].

`executescript(sql_script, /)`

Execute the SQL statements in *sql\_script*. If there is a pending transaction, an implicit `COMMIT` statement is executed first. No other implicit transaction control is performed; any transaction control must be added to *sql\_script*.

*sql\_script* must be a **string**.

Example:

```
# cur is an sqlite3.Cursor object
cur.executescript("""
    BEGIN;
    CREATE TABLE person(firstname, lastname, age);
    CREATE TABLE book(title, author, published);
    CREATE TABLE publisher(name, address);
    COMMIT;
""")
```

`fetchone()`

If **row\_factory** is `None`, return the next row query result set as a **tuple**. Else, pass it to the row factory and return its result. Return `None` if no more data is available.

`fetchmany(size = cursor.arraysize)`

Return the next set of rows of a query result as a **list**. Return an empty list if no more rows are available.

The number of rows to fetch per call is specified by the

*size* parameter. If *size* is not given, **arraysize** determines the number of rows to be fetched. If fewer than *size* rows are available, as many rows as are available are returned.

Note there are performance considerations involved with the *size* parameter. For optimal performance, it is usually best to use the **arraysize** attribute. If the *size* parameter is used, then it is best for it to retain the same value from one **fetchmany()** call to the next.

## fetchall()

Return all (remaining) rows of a query result as a **list**. Return an empty list if no rows are available. Note that the **arraysize** attribute can affect the performance of this operation.

## close()

Close the cursor now (rather than whenever `__del__` is called).

The cursor will be unusable from this point forward; a **ProgrammingError** exception will be raised if any operation is attempted with the cursor.

## setinputsizes(sizes, /)

Required by the DB-API. Does nothing in **sqlite3**.

## setoutputsize(size, column=None, /)

Required by the DB-API. Does nothing in **sqlite3**.

## arraysize

Read/write attribute that controls the number of rows returned by **fetchmany()**. The default value is 1 which means a single row would be fetched per call.

## connection

Read-only attribute that provides the SQLite database **Connection** belonging to the cursor. A **Cursor** object created by calling **con.cursor()** will have a **connection** attribute that refers to *con*:

```
>>> con = sqlite3.connect(":memory:")
>>> cur = con.cursor()
>>> cur.connection == con
True
```

### description

Read-only attribute that provides the column names of the last query. To remain compatible with the Python DB API, it returns a 7-tuple for each column where the last six items of each tuple are *None*.

It is set for *SELECT* statements without any matching rows as well.

### lastrowid

Read-only attribute that provides the row id of the last inserted row. It is only updated after successful *INSERT* or *REPLACE* statements using the **execute()** method. For other statements, after **executemany()** or **executescript()**, or if the insertion failed, the value of *lastrowid* is left unchanged. The initial value of *lastrowid* is *None*.

### Note

Inserts into *WITHOUT ROWID* tables are not recorded.

*Changed in version 3.6:* Added support for the *REPLACE* statement.

### rowcount

Read-only attribute that provides the number of modified rows for *INSERT*, *UPDATE*, *DELETE*, and

REPLACE statements; is `-1` for other statements, including CTE queries. It is only updated by the `execute()` and `executemany()` methods, after the statement has run to completion. This means that any resulting rows must be fetched in order for `rowcount` to be updated.

## `row_factory`

Control how a row fetched from this `Cursor` is represented. If `None`, a row is represented as a `tuple`. Can be set to the included `sqlite3.Row`; or a callable that accepts two arguments, a `Cursor` object and the `tuple` of row values, and returns a custom object representing an SQLite row.

Defaults to what `Connection.row_factory` was set to when the `Cursor` was created. Assigning to this attribute does not affect `Connection.row_factory` of the parent connection.

See [How to create and use row factories](#) for more details.

## Row objects

### `class sqlite3.Row`

A `Row` instance serves as a highly optimized `row_factory` for `Connection` objects. It supports iteration, equality testing, `len()`, and `mapping` access by column name and index.

Two `Row` objects compare equal if they have identical column names and values.

See [How to create and use row factories](#) for more details.

### `keys()`

Return a `list` of column names as `strings`. Immediately after a query, it is the first member of each

tuple in `Cursor.description`.

*Changed in version 3.5:* Added support of slicing.

## Blob objects

*New in version 3.11.*

`class sqlite3.Blob`

A **Blob** instance is a [file-like object](#) that can read and write data in an SQLite BLOB. Call `len(blob)` to get the size (number of bytes) of the blob. Use indices and [slices](#) for direct access to the blob data.

Use the **Blob** as a [context manager](#) to ensure that the blob handle is closed after use.

```
con = sqlite3.connect(":memory:")
con.execute("CREATE TABLE test(blob_col blob)")
con.execute("INSERT INTO test(blob_col) VALUES(zer0)")

# Write to our blob, using two write operations:
with con.blobopen("test", "blob_col", 1) as blob:
    blob.write(b"hello, ")
    blob.write(b"world.")
    # Modify the first and last bytes of our blob
    blob[0] = ord("H")
    blob[-1] = ord("!")

# Read the contents of our blob
with con.blobopen("test", "blob_col", 1) as blob:
    greeting = blob.read()

print(greeting)  # outputs "b'Hello, world!'"

close()
```

Close the blob.

The blob will be unusable from this point onward. An

**Error** (or subclass) exception will be raised if any further operation is attempted with the blob.

`read(length = - 1, /)`

Read *length* bytes of data from the blob at the current offset position. If the end of the blob is reached, the data up to EOF will be returned. When *length* is not specified, or is negative, `read()` will read until the end of the blob.

`write(data, /)`

Write *data* to the blob at the current offset. This function cannot change the blob length. Writing beyond the end of the blob will raise **ValueError**.

`tell()`

Return the current access position of the blob.

`seek(offset, origin = os.SEEK_SET, /)`

Set the current access position of the blob to *offset*. The *origin* argument defaults to `os.SEEK_SET` (absolute blob positioning). Other values for *origin* are `os.SEEK_CUR` (seek relative to the current position) and `os.SEEK_END` (seek relative to the blob's end).

## PrepareProtocol objects

`class sqlite3.PrepareProtocol`

The PrepareProtocol type's single purpose is to act as a **PEP 246** [<https://peps.python.org/pep-0246/>] style adaption protocol for objects that can **adapt themselves** to **native SQLite types**.

## Exceptions

The exception hierarchy is defined by the DB-API 2.0 (**PEP 249** [<https://peps.python.org/pep-0249/>]).

### *exception* sqlite3.Warning

This exception is not currently raised by the `sqlite3` module, but may be raised by applications using `sqlite3`, for example if a user-defined function truncates data while inserting. `Warning` is a subclass of `Exception`.

### *exception* sqlite3.Error

The base class of the other exceptions in this module. Use this to catch all errors with one single `except` statement. `Error` is a subclass of `Exception`.

If the exception originated from within the SQLite library, the following two attributes are added to the exception:

#### `sqlite_errcode`

The numeric error code from the [SQLite API](https://sqlite.org/rescode.html) [https://sqlite.org/rescode.html]

*New in version 3.11.*

#### `sqlite_errname`

The symbolic name of the numeric error code from the [SQLite API](https://sqlite.org/rescode.html) [https://sqlite.org/rescode.html]

*New in version 3.11.*

### *exception* sqlite3.InterfaceError

Exception raised for misuse of the low-level SQLite C API. In other words, if this exception is raised, it probably indicates a bug in the `sqlite3` module. `InterfaceError` is a subclass of `Error`.

### *exception* sqlite3.DatabaseError

Exception raised for errors that are related to the database. This serves as the base exception for several types of database errors. It is only raised implicitly through the specialised subclasses. `DatabaseError` is a subclass of `Error`.

### *exception* sqlite3.DataError

Exception raised for errors caused by problems with the processed data, like numeric values out of range, and strings which are too long. `DataError` is a subclass of `DatabaseError`.

*exception* `sqlite3.OperationalError`

Exception raised for errors that are related to the database's operation, and not necessarily under the control of the programmer. For example, the database path is not found, or a transaction could not be processed. `OperationalError` is a subclass of `DatabaseError`.

*exception* `sqlite3.IntegrityError`

Exception raised when the relational integrity of the database is affected, e.g. a foreign key check fails. It is a subclass of `DatabaseError`.

*exception* `sqlite3.InternalError`

Exception raised when SQLite encounters an internal error. If this is raised, it may indicate that there is a problem with the runtime SQLite library. `InternalError` is a subclass of `DatabaseError`.

*exception* `sqlite3.ProgrammingError`

Exception raised for **sqlite3** API programming errors, for example supplying the wrong number of bindings to a query, or trying to operate on a closed `Connection`.

`ProgrammingError` is a subclass of `DatabaseError`.

*exception* `sqlite3.NotSupportedError`

Exception raised in case a method or database API is not supported by the underlying SQLite library. For example, setting *deterministic* to `True` in `create_function()`, if the underlying SQLite library does not support deterministic functions. `NotSupportedError` is a subclass of `DatabaseError`.

## SQLite and Python types

SQLite natively supports the following types: `NULL`, `INTEGER`, `REAL`, `TEXT`, `BLOB`.

The following Python types can thus be sent to SQLite without any problem:

| SQLite type          |
|----------------------|
| <code>NULL</code>    |
| <code>INTEGER</code> |
| <code>REAL</code>    |
| <code>TEXT</code>    |
| <code>BLOB</code>    |

This is how SQLite types are converted to Python types by default:

| SQLite type                                                        |
|--------------------------------------------------------------------|
| <code>NULL</code>                                                  |
| <code>INTEGER</code>                                               |
| <code>REAL</code>                                                  |
| depends on <code>text_factory</code> , <code>str</code> by default |
| <code>BLOB</code>                                                  |

The type system of the `sqlite3` module is extensible in two ways: you can store additional Python types in an SQLite database via [object adapters](#), and you can let the `sqlite3` module convert SQLite types to Python types via [converters](#).

## Default adapters and converters

There are default adapters for the date and datetime types in the `datetime` module. They will be sent as ISO dates/ISO timestamps to SQLite.

The default converters are registered under the name “date” for `datetime.date` and under the name “timestamp” for `datetime.datetime`.

This way, you can use date/timestamps from Python without any additional fiddling in most cases. The format of the adapters is also compatible with the experimental SQLite date/time functions.

The following example demonstrates this.

```
import sqlite3
import datetime

con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES)
cur = con.cursor()
cur.execute("create table test(d date, ts timestamp)")

today = datetime.date.today()
now = datetime.datetime.now()

cur.execute("insert into test(d, ts) values (?, ?)", (today, now))
cur.execute("select d, ts from test")
row = cur.fetchone()
print(today, "=>", row[0], type(row[0]))
print(now, "=>", row[1], type(row[1]))

cur.execute('select current_date as "d [date]", current_timestamp as "ts [timestamp]"')
row = cur.fetchone()
print("current_date", row[0], type(row[0]))
print("current_timestamp", row[1], type(row[1]))

con.close()
```

If a timestamp stored in SQLite has a fractional part longer than 6 numbers, its value will be truncated to microsecond precision by the timestamp converter.

### Note

The default “timestamp” converter ignores UTC offsets in the database and always returns a naive `datetime.datetime` object. To preserve UTC offsets in timestamps, either leave converters disabled, or register an offset-aware converter with `register_converter()`.

## How-to guides

## How to use placeholders to bind values in SQL queries

SQL operations usually need to use values from Python variables. However, beware of using Python's string operations to assemble queries, as they are vulnerable to [SQL injection attacks](https://en.wikipedia.org/wiki/SQL_injection) [https://en.wikipedia.org/wiki/SQL\_injection]. For example, an attacker can simply close the single quote and inject `OR TRUE` to select all rows:

```
>>> # Never do this -- insecure!
>>> symbol = input()
' OR TRUE; --
>>> sql = "SELECT * FROM stocks WHERE symbol = '%s'" % s
>>> print(sql)
SELECT * FROM stocks WHERE symbol = '' OR TRUE; --'
>>> cur.execute(sql)
```

Instead, use the DB-API's parameter substitution. To insert a variable into a query string, use a placeholder in the string, and substitute the actual values into the query by providing them as a [tuple](#) of values to the second argument of the cursor's [execute\(\)](#) method.

An SQL statement may use one of two kinds of placeholders: question marks (qmark style) or named placeholders (named style). For the qmark style, *parameters* must be a [sequence](#) whose length must match the number of placeholders, or a [ProgrammingError](#) is raised. For the named style, *parameters* should be an instance of a [dict](#) (or a subclass), which must contain keys for all named parameters; any extra items are ignored. Here's an example of both styles:

```
con = sqlite3.connect(":memory:")
cur = con.execute("CREATE TABLE lang(name, first_appeared)")

# This is the named style used with executemany():
data = (
    {"name": "C", "year": 1972},
    {"name": "Fortran", "year": 1957},
    {"name": "Python", "year": 1991},
    {"name": "Go", "year": 2009},
```

```
)
cur.executemany("INSERT INTO lang VALUES(:name, :year)",
# This is the qmark style used in a SELECT query:
params = (1972,)
cur.execute("SELECT * FROM lang WHERE first_appeared = ?")
print(cur.fetchall())
```

## Note

**PEP 249** [<https://peps.python.org/pep-0249/>] numeric placeholders are *not* supported. If used, they will be interpreted as named placeholders.

## How to adapt custom Python types to SQLite values

SQLite supports only a limited set of data types natively. To store custom Python types in SQLite databases, *adapt* them to one of the [Python types SQLite natively understands](#).

There are two ways to adapt Python objects to SQLite types: letting your object adapt itself, or using an *adapter callable*. The latter will take precedence above the former. For a library that exports a custom type, it may make sense to enable that type to adapt itself. As an application developer, it may make more sense to take direct control by registering custom adapter functions.

## How to write adaptable objects

Suppose we have a **Point** class that represents a pair of coordinates, `x` and `y`, in a Cartesian coordinate system. The coordinate pair will be stored as a text string in the database, using a semicolon to separate the coordinates. This can be implemented by adding a `__conform__(self, protocol)` method which returns the adapted value. The object passed to *protocol* will be of type [PrepareProtocol](#).

```
class Point:
    def __init__(self, x, y):
```

```

        self.x, self.y = x, y

    def __conform__(self, protocol):
        if protocol is sqlite3.PrepareProtocol:
            return f"{self.x};{self.y}"

con = sqlite3.connect(":memory:")
cur = con.cursor()

cur.execute("SELECT ?", (Point(4.0, -3.2),))
print(cur.fetchone()[0])

```

## How to register adapter callables

The other possibility is to create a function that converts the Python object to an SQLite-compatible type. This function can then be registered using `register_adapter()`.

```

class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

def adapt_point(point):
    return f"{point.x};{point.y}"

sqlite3.register_adapter(Point, adapt_point)

con = sqlite3.connect(":memory:")
cur = con.cursor()

cur.execute("SELECT ?", (Point(1.0, 2.5),))
print(cur.fetchone()[0])

```

## How to convert SQLite values to custom Python types

Writing an adapter lets you convert *from* custom Python types *to* SQLite values. To be able to convert *from* SQLite values *to* custom Python types, we use *converters*.

Let's go back to the **Point** class. We stored the x and y coordinates separated via semicolons as strings in SQLite.

First, we'll define a converter function that accepts the string as a parameter and constructs a **Point** object from it.

## Note

Converter functions are **always** passed a **bytes** object, no matter the underlying SQLite data type.

```
def convert_point(s):
    x, y = map(float, s.split(b";"))
    return Point(x, y)
```

We now need to tell **sqlite3** when it should convert a given SQLite value. This is done when connecting to a database, using the *detect\_types* parameter of **connect()**. There are three options:

- Implicit: set *detect\_types* to **PARSE\_DECLTYPES**
- Explicit: set *detect\_types* to **PARSE\_COLNAMES**
- Both: set *detect\_types* to `sqlite3.PARSE_DECLTYPES | sqlite3.PARSE_COLNAMES`. Column names take precedence over declared types.

The following example illustrates the implicit and explicit approaches:

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __repr__(self):
        return f"Point({self.x}, {self.y})"

def adapt_point(point):
    return f"{point.x};{point.y}"

def convert_point(s):
    x, y = list(map(float, s.split(b";")))
```

```

        return Point(x, y)

# Register the adapter and converter
sqlite3.register_adapter(Point, adapt_point)
sqlite3.register_converter("point", convert_point)

# 1) Parse using declared types
p = Point(4.0, -3.2)
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES)
cur = con.execute("CREATE TABLE test(p point)")

cur.execute("INSERT INTO test(p) VALUES(?)", (p,))
cur.execute("SELECT p FROM test")
print("with declared types:", cur.fetchone()[0])
cur.close()
con.close()

# 2) Parse using column names
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_COLUMN_NAMES)
cur = con.execute("CREATE TABLE test(p)")

cur.execute("INSERT INTO test(p) VALUES(?)", (p,))
cur.execute('SELECT p AS "p [point]" FROM test')
print("with column names:", cur.fetchone()[0])

```

## Adapter and converter recipes

This section shows recipes for common adapters and converters.

```

import datetime
import sqlite3

def adapt_date_iso(val):
    """Adapt datetime.date to ISO 8601 date."""
    return val.isoformat()

def adapt_datetime_iso(val):
    """Adapt datetime.datetime to timezone-naive ISO 8601 datetime"""
    return val.isoformat()

```

```

def adapt_datetime_epoch(val):
    """Adapt datetime.datetime to Unix timestamp."""
    return int(val.timestamp())

sqlite3.register_adapter(datetime.date, adapt_date_iso)
sqlite3.register_adapter(datetime.datetime, adapt_datetime_epoch)
sqlite3.register_adapter(datetime.datetime, adapt_datetime_epoch)

def convert_date(val):
    """Convert ISO 8601 date to datetime.date object."""
    return datetime.date.fromisoformat(val.decode())

def convert_datetime(val):
    """Convert ISO 8601 datetime to datetime.datetime object."""
    return datetime.datetime.fromisoformat(val.decode())

def convert_timestamp(val):
    """Convert Unix epoch timestamp to datetime.datetime object."""
    return datetime.datetime.fromtimestamp(int(val))

sqlite3.register_converter("date", convert_date)
sqlite3.register_converter("datetime", convert_datetime)
sqlite3.register_converter("timestamp", convert_timestamp)

```

## How to use connection shortcut methods

Using the `execute()`, `executemany()`, and `executescript()` methods of the `Connection` class, your code can be written more concisely because you don't have to create the (often superfluous) `Cursor` objects explicitly. Instead, the `Cursor` objects are created implicitly and these shortcut methods return the cursor objects. This way, you can execute a `SELECT` statement and iterate over it directly using only a single call on the `Connection` object.

```

# Create and fill the table.
con = sqlite3.connect(":memory:")
con.execute("CREATE TABLE lang(name, first_appeared)")

```

```

data = [
    ("C++", 1985),
    ("Objective-C", 1984),
]
con.executemany("INSERT INTO lang(name, first_appeared)

# Print the table contents
for row in con.execute("SELECT name, first_appeared FROM
    print(row)

print("I just deleted", con.execute("DELETE FROM lang").

# close() is not a shortcut method and it's not called a
# the connection object should be closed manually
con.close()

```

## How to use the connection context manager

A **Connection** object can be used as a context manager that automatically commits or rolls back open transactions when leaving the body of the context manager. If the body of the **with** statement finishes without exceptions, the transaction is committed. If this commit fails, or if the body of the **with** statement raises an uncaught exception, the transaction is rolled back.

If there is no open transaction upon leaving the body of the **with** statement, the context manager is a no-op.

### Note

The context manager neither implicitly opens a new transaction nor closes the connection.

```

con = sqlite3.connect(":memory:")
con.execute("CREATE TABLE lang(id INTEGER PRIMARY KEY, n

# Successful, con.commit() is called automatically after
with con:
    con.execute("INSERT INTO lang(name) VALUES(?)", ("Py

```

```
# con.rollback() is called after the with block finishes
# the exception is still raised and must be caught
try:
    with con:
        con.execute("INSERT INTO lang(name) VALUES(?)",
except sqlite3.IntegrityError:
    print("couldn't add Python twice")

# Connection object used as context manager only commits
# so the connection object should be closed manually
con.close()
```

## How to work with SQLite URIs

Some useful URI tricks include:

- Open a database in read-only mode:

```
>>> con = sqlite3.connect("file:tutorial.db?mode=ro", uri=True)
>>> con.execute("CREATE TABLE readonly(data)")
Traceback (most recent call last):
OperationalError: attempt to write a readonly database
```

- Do not implicitly create a new database file if it does not already exist; will raise **OperationalError** if unable to create a new file:

```
>>> con = sqlite3.connect("file:nosuchdb.db?mode=rw", uri=True)
Traceback (most recent call last):
OperationalError: unable to open database file
```

- Create a shared named in-memory database:

```
db = "file:mem1?mode=memory&cache=shared"
con1 = sqlite3.connect(db, uri=True)
con2 = sqlite3.connect(db, uri=True)
with con1:
    con1.execute("CREATE TABLE shared(data)")
    con1.execute("INSERT INTO shared VALUES(28)")
```

```
res = con2.execute("SELECT data FROM shared")
assert res.fetchone() == (28,)
```

More information about this feature, including a list of parameters, can be found in the [SQLite URI documentation](https://www.sqlite.org/uri.html) [https://www.sqlite.org/uri.html].

## How to create and use row factories

By default, **sqlite3** represents each row as a **tuple**. If a **tuple** does not suit your needs, you can use the **sqlite3.Row** class or a custom **row\_factory**.

While **row\_factory** exists as an attribute both on the **Cursor** and the **Connection**, it is recommended to set **Connection.row\_factory**, so all cursors created from the connection will use the same row factory.

**Row** provides indexed and case-insensitive named access to columns, with minimal memory overhead and performance impact over a **tuple**. To use **Row** as a row factory, assign it to the **row\_factory** attribute:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = sqlite3.Row
```

Queries now return **Row** objects:

```
>>> res = con.execute("SELECT 'Earth' AS name, 6378 AS r")
>>> row = res.fetchone()
>>> row.keys()
['name', 'radius']
>>> row[0]           # Access by index.
'Earth'
>>> row["name"]      # Access by name.
'Earth'
>>> row["RADIUS"]    # Column names are case-insensitive.
6378
```

You can create a custom **row\_factory** that returns each row as a

**dict**, with column names mapped to values:

```
def dict_factory(cursor, row):
    fields = [column[0] for column in cursor.description]
    return {key: value for key, value in zip(fields, row)}
```

Using it, queries now return a **dict** instead of a **tuple**:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = dict_factory
>>> for row in con.execute("SELECT 1 AS a, 2 AS b"):
...     print(row)
{'a': 1, 'b': 2}
```

The following row factory returns a **named tuple**:

```
from collections import namedtuple

def namedtuple_factory(cursor, row):
    fields = [column[0] for column in cursor.description]
    cls = namedtuple("Row", fields)
    return cls._make(row)
```

**namedtuple\_factory()** can be used as follows:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = namedtuple_factory
>>> cur = con.execute("SELECT 1 AS a, 2 AS b")
>>> row = cur.fetchone()
>>> row
Row(a=1, b=2)
>>> row[0]    # Indexed access.
1
>>> row.b     # Attribute access.
2
```

With some adjustments, the above recipe can be adapted to use a **dataclass**, or any other custom class, instead of a **namedtuple**.

## Explanation

## Transaction control

The **sqlite3** module does not adhere to the transaction handling recommended by **PEP 249** [<https://peps.python.org/pep-0249/>].

If the connection attribute **isolation\_level** is not `None`, new transactions are implicitly opened before **execute()** and **executemany()** executes `INSERT`, `UPDATE`, `DELETE`, or `REPLACE` statements; for other statements, no implicit transaction handling is performed. Use the **commit()** and **rollback()** methods to respectively commit and roll back pending transactions. You can choose the underlying **SQLite transaction behaviour** [[https://www.sqlite.org/lang\\_transaction.html#deferred\\_immediate\\_and\\_exclusive\\_transactions](https://www.sqlite.org/lang_transaction.html#deferred_immediate_and_exclusive_transactions)] — that is, whether and what type of `BEGIN` statements **sqlite3** implicitly executes – via the **isolation\_level** attribute.

If **isolation\_level** is set to `None`, no transactions are implicitly opened at all. This leaves the underlying SQLite library in **autocommit mode** [[https://www.sqlite.org/lang\\_transaction.html#implicit\\_versus\\_explicit\\_transactions](https://www.sqlite.org/lang_transaction.html#implicit_versus_explicit_transactions)], but also allows the user to perform their own transaction handling using explicit SQL statements. The underlying SQLite library autocommit mode can be queried using the **in\_transaction** attribute.

The **executescript()** method implicitly commits any pending transaction before execution of the given SQL script, regardless of the value of **isolation\_level**.

*Changed in version 3.6:* **sqlite3** used to implicitly commit an open transaction before DDL statements. This is no longer the case.

# Data Compression and Archiving

The modules described in this chapter support data compression with the `zlib`, `gzip`, `bzip2` and `lzma` algorithms, and the creation of ZIP- and tar-format archives. See also [Archiving operations](#) provided by the `shutil` module.

- **zlib** — Compression compatible with **gzip**
- **gzip** — Support for **gzip** files
  - Examples of usage
  - Command Line Interface
- Command line options
- **bz2** — Support for **bzip2** compression
  - (De)compression of files
  - Incremental (de)compression
  - One-shot (de)compression
  - Examples of usage
- **lzma** — Compression using the LZMA algorithm
  - Reading and writing compressed files
  - Compressing and decompressing data in memory
  - Miscellaneous
  - Specifying custom filter chains
  - Examples
- **zipfile** — Work with ZIP archives
  - ZipFile Objects
  - Path Objects
  - PyZipFile Objects

- ZipInfo Objects
- Command-Line Interface
  - Command-line options
- Decompression pitfalls
  - From file itself
  - File System limitations
  - Resources limitations
  - Interruption
  - Default behaviors of extraction
- **tarfile** — Read and write tar archive files
  - TarFile Objects
  - TarInfo Objects
  - Extraction filters
    - Default named filters
    - Filter errors
    - Hints for further verification
    - Supporting older Python versions
    - Stateful extraction filter example
  - Command-Line Interface
    - Command-line options
  - Examples
  - Supported tar formats
  - Unicode issues

# zlib — Compression compatible with gzip

---

For applications that require data compression, the functions in this module allow compression and decompression, using the zlib library. The zlib library has its own home page at <https://www.zlib.net>. There are known incompatibilities between the Python module and versions of the zlib library earlier than 1.1.3; 1.1.3 has a [security vulnerability](https://zlib.net/zlib_faq.html#faq33) [https://zlib.net/zlib\_faq.html#faq33], so we recommend using 1.1.4 or later.

zlib's functions have many options and often need to be used in a particular order. This documentation doesn't attempt to cover all of the permutations; consult the zlib manual at <http://www.zlib.net/manual.html> for authoritative information.

For reading and writing `.gz` files see the [gzip](#) module.

The available exception and functions in this module are:

*exception* `zlib.error`

Exception raised on compression and decompression errors.

`zlib.adler32(data[, value])`

Computes an Adler-32 checksum of *data*. (An Adler-32 checksum is almost as reliable as a CRC32 but can be computed much more quickly.) The result is an unsigned 32-bit integer. If *value* is present, it is used as the starting value of the checksum; otherwise, a default value of 1 is used. Passing in *value* allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable

for use as a general hash algorithm.

*Changed in version 3.0:* The result is always unsigned.

`zlib.compress(data, /, level=-1, wbits=MAX_WBITS)`

Compresses the bytes in *data*, returning a bytes object containing compressed data. *level* is an integer from 0 to 9 or -1 controlling the level of compression; 1 (Z\_BEST\_SPEED) is fastest and produces the least compression, 9 (Z\_BEST\_COMPRESSION) is slowest and produces the most. 0 (Z\_NO\_COMPRESSION) is no compression. The default value is -1 (Z\_DEFAULT\_COMPRESSION). Z\_DEFAULT\_COMPRESSION represents a default compromise between speed and compression (currently equivalent to level 6).

The *wbits* argument controls the size of the history buffer (or the “window size”) used when compressing data, and whether a header and trailer is included in the output. It can take several ranges of values, defaulting to 15 (MAX\_WBITS):

- +9 to +15: The base-two logarithm of the window size, which therefore ranges between 512 and 32768. Larger values produce better compression at the expense of greater memory usage. The resulting output will include a zlib-specific header and trailer.
- -9 to -15: Uses the absolute value of *wbits* as the window size logarithm, while producing a raw output stream with no header or trailing checksum.
- +25 to +31 = 16 + (9 to 15): Uses the low 4 bits of the value as the window size logarithm, while including a basic **gzip** header and trailing checksum in the output.

Raises the `error` exception if any error occurs.

*Changed in version 3.6:* *level* can now be used as a keyword parameter.

*Changed in version 3.11:* The *wbits* parameter is now available

to set window bits and compression type.

```
zlib.compressobj(level=-1, method=DEFLATED,  
wbits=MAX_WBITS, memLevel=DEF_MEM_LEVEL,  
strategy=Z_DEFAULT_STRATEGY[, zdict])
```

Returns a compression object, to be used for compressing data streams that won't fit into memory at once.

*level* is the compression level – an integer from 0 to 9 or -1. A value of 1 (Z\_BEST\_SPEED) is fastest and produces the least compression, while a value of 9 (Z\_BEST\_COMPRESSION) is slowest and produces the most. 0 (Z\_NO\_COMPRESSION) is no compression. The default value is -1 (Z\_DEFAULT\_COMPRESSION). Z\_DEFAULT\_COMPRESSION represents a default compromise between speed and compression (currently equivalent to level 6).

*method* is the compression algorithm. Currently, the only supported value is **DEFLATED**.

The *wbits* parameter controls the size of the history buffer (or the “window size”), and what header and trailer format will be used. It has the same meaning as [described for compress\(\)](#).

The *memLevel* argument controls the amount of memory used for the internal compression state. Valid values range from 1 to 9. Higher values use more memory, but are faster and produce smaller output.

*strategy* is used to tune the compression algorithm. Possible values are **Z\_DEFAULT\_STRATEGY**, **Z\_FILTERED**, **Z\_HUFFMAN\_ONLY**, **Z\_RLE** (zlib 1.2.0.1) and **Z\_FIXED** (zlib 1.2.2.2).

*zdict* is a predefined compression dictionary. This is a sequence of bytes (such as a [bytes](#) object) containing subsequences that are expected to occur frequently in the data that is to be compressed. Those subsequences that are expected to be most common should come at the end of the dictionary.

*Changed in version 3.3:* Added the *zdict* parameter and keyword argument support.

`zlib.crc32(data[, value])`

Computes a CRC (Cyclic Redundancy Check) checksum of *data*. The result is an unsigned 32-bit integer. If *value* is present, it is used as the starting value of the checksum; otherwise, a default value of 0 is used. Passing in *value* allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm.

*Changed in version 3.0:* The result is always unsigned.

`zlib.decompress(data, /, wbits = MAX_WBITS,  
bufsize = DEF_BUF_SIZE)`

Decompresses the bytes in *data*, returning a bytes object containing the uncompressed data. The *wbits* parameter depends on the format of *data*, and is discussed further below. If *bufsize* is given, it is used as the initial size of the output buffer. Raises the `error` exception if any error occurs.

The *wbits* parameter controls the size of the history buffer (or “window size”), and what header and trailer format is expected. It is similar to the parameter for `compressobj()`, but accepts more ranges of values:

- +8 to +15: The base-two logarithm of the window size. The input must include a zlib header and trailer.
- 0: Automatically determine the window size from the zlib header. Only supported since zlib 1.2.3.5.
- -8 to -15: Uses the absolute value of *wbits* as the window size logarithm. The input must be a raw stream with no header or trailer.
- +24 to +31 = 16 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm. The input must

- include a gzip header and trailer.
- +40 to +47 = 32 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm, and automatically accepts either the zlib or gzip format.

When decompressing a stream, the window size must not be smaller than the size originally used to compress the stream; using a too-small value may result in an **error** exception. The default *wbits* value corresponds to the largest window size and requires a zlib header and trailer to be included.

*bufsize* is the initial size of the buffer used to hold decompressed data. If more space is required, the buffer size will be increased as needed, so you don't have to get this value exactly right; tuning it will only save a few calls to **malloc()**.

*Changed in version 3.6:* *wbits* and *bufsize* can be used as keyword arguments.

**zlib.decompressobj(*wbits*=MAX\_WBITS[, *zdict*])**

Returns a decompression object, to be used for decompressing data streams that won't fit into memory at once.

The *wbits* parameter controls the size of the history buffer (or the “window size”), and what header and trailer format is expected. It has the same meaning as [described for decompress\(\)](#).

The *zdict* parameter specifies a predefined compression dictionary. If provided, this must be the same dictionary as was used by the compressor that produced the data that is to be decompressed.

### Note

If *zdict* is a mutable object (such as a **bytearray**), you must not modify its contents between the call to **decompressobj()** and the first call to the decompressor's **decompress()** method.

*Changed in version 3.3:* Added the `zdict` parameter.

Compression objects support the following methods:

`Compress.compress(data)`

Compress `data`, returning a bytes object containing compressed data for at least part of the data in `data`. This data should be concatenated to the output produced by any preceding calls to the `compress()` method. Some input may be kept in internal buffers for later processing.

`Compress.flush([mode])`

All pending input is processed, and a bytes object containing the remaining compressed output is returned. `mode` can be selected from the constants `Z_NO_FLUSH`, `Z_PARTIAL_FLUSH`, `Z_SYNC_FLUSH`, `Z_FULL_FLUSH`, `Z_BLOCK` (zlib 1.2.3.4), or `Z_FINISH`, defaulting to `Z_FINISH`. Except `Z_FINISH`, all constants allow compressing further bytestrings of data, while `Z_FINISH` finishes the compressed stream and prevents compressing any more data. After calling `flush()` with `mode` set to `Z_FINISH`, the `compress()` method cannot be called again; the only realistic action is to delete the object.

`Compress.copy()`

Returns a copy of the compression object. This can be used to efficiently compress a set of data that share a common initial prefix.

*Changed in version 3.8:* Added `copy.copy()` and `copy.deepcopy()` support to compression objects.

Decompression objects support the following methods and attributes:

`Decompress.unused_data`

A bytes object which contains any bytes past the end of the compressed data. That is, this remains `b""` until the last byte

that contains compression data is available. If the whole bytestring turned out to contain compressed data, this is `b""`, an empty bytes object.

#### `Decompress.unconsumed_tail`

A bytes object that contains any data that was not consumed by the last `decompress()` call because it exceeded the limit for the uncompressed data buffer. This data has not yet been seen by the zlib machinery, so you must feed it (possibly with further data concatenated to it) back to a subsequent `decompress()` method call in order to get correct output.

#### `Decompress.eof`

A boolean indicating whether the end of the compressed data stream has been reached.

This makes it possible to distinguish between a properly formed compressed stream, and an incomplete or truncated one.

*New in version 3.3.*

#### `Decompress.decompress(data, max_length=0)`

Decompress *data*, returning a bytes object containing the uncompressed data corresponding to at least part of the data in *string*. This data should be concatenated to the output produced by any preceding calls to the `decompress()` method. Some of the input data may be preserved in internal buffers for later processing.

If the optional parameter *max\_length* is non-zero then the return value will be no longer than *max\_length*. This may mean that not all of the compressed input can be processed; and unconsumed data will be stored in the attribute `unconsumed_tail`. This bytestring must be passed to a subsequent call to `decompress()` if decompression is to continue. If *max\_length* is zero then the whole input is decompressed, and `unconsumed_tail` is empty.

*Changed in version 3.6:* `max_length` can be used as a keyword argument.

`Decompress.flush([length])`

All pending input is processed, and a bytes object containing the remaining uncompressed output is returned. After calling `flush()`, the `decompress()` method cannot be called again; the only realistic action is to delete the object.

The optional parameter *length* sets the initial size of the output buffer.

`Decompress.copy()`

Returns a copy of the decompression object. This can be used to save the state of the decompressor midway through the data stream in order to speed up random seeks into the stream at a future point.

*Changed in version 3.8:* Added `copy.copy()` and `copy.deepcopy()` support to decompression objects.

Information about the version of the zlib library in use is available through the following constants:

`zlib.ZLIB_VERSION`

The version string of the zlib library that was used for building the module. This may be different from the zlib library actually used at runtime, which is available as `ZLIB_RUNTIME_VERSION`.

`zlib.ZLIB_RUNTIME_VERSION`

The version string of the zlib library actually loaded by the interpreter.

*New in version 3.3.*

# gzip — Support for gzip files

**Source code:** [Lib/gzip.py](https://github.com/python/cpython/tree/3.11/Lib/gzip.py) [<https://github.com/python/cpython/tree/3.11/Lib/gzip.py>]

---

This module provides a simple interface to compress and decompress files just like the GNU programs **gzip** and **gunzip** would.

The data compression is provided by the **zlib** module.

The **gzip** module provides the **GzipFile** class, as well as the **open()**, **compress()** and **decompress()** convenience functions. The **GzipFile** class reads and writes **gzip**-format files, automatically compressing or decompressing the data so that it looks like an ordinary [file object](#).

Note that additional file formats which can be decompressed by the **gzip** and **gunzip** programs, such as those produced by **compress** and **pack**, are not supported by this module.

The module defines the following items:

`gzip.open(filename, mode='rb', compresslevel=9, encoding=None, errors=None, newline=None)`

Open a gzip-compressed file in binary or text mode, returning a [file object](#).

The *filename* argument can be an actual filename (a **str** or **bytes** object), or an existing file object to read from or write to.

The *mode* argument can be any of `'r'`, `'rb'`, `'a'`, `'ab'`, `'w'`, `'wb'`, `'x'` or `'xb'` for binary mode, or `'rt'`, `'at'`, `'wt'`, or `'xt'` for text mode. The default is `'rb'`.

The *compresslevel* argument is an integer from 0 to 9, as for the `GzipFile` constructor.

For binary mode, this function is equivalent to the `GzipFile` constructor: `GzipFile(filename, mode, compresslevel)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a `GzipFile` object is created, and wrapped in an `io.TextIOWrapper` instance with the specified encoding, error handling behavior, and line ending(s).

*Changed in version 3.3:* Added support for *filename* being a file object, support for text mode, and the *encoding*, *errors* and *newline* arguments.

*Changed in version 3.4:* Added support for the `'x'`, `'xb'` and `'xt'` modes.

*Changed in version 3.6:* Accepts a [path-like object](#).

#### *exception* `gzip.BadGzipFile`

An exception raised for invalid gzip files. It inherits `OSError`. `EOFError` and `zlib.error` can also be raised for invalid gzip files.

*New in version 3.8.*

`class gzip.GzipFile(filename=None, mode=None, compresslevel=9, fileobj=None, mtime=None)`

Constructor for the `GzipFile` class, which simulates most of the methods of a [file object](#), with the exception of the `truncate()` method. At least one of *fileobj* and *filename* must be given a non-trivial value.

The new class instance is based on *fileobj*, which can be a regular file, an `io.BytesIO` object, or any other object which simulates a file. It defaults to `None`, in which case *filename* is opened to provide a file object.

When *fileobj* is not `None`, the *filename* argument is only used to be included in the **gzip** file header, which may include the original filename of the uncompressed file. It defaults to the filename of *fileobj*, if discernible; otherwise, it defaults to the empty string, and in this case the original filename is not included in the header.

The *mode* argument can be any of `'r'`, `'rb'`, `'a'`, `'ab'`, `'w'`, `'wb'`, `'x'`, or `'xb'`, depending on whether the file will be read or written. The default is the mode of *fileobj* if discernible; otherwise, the default is `'rb'`. In future Python releases the mode of *fileobj* will not be used. It is better to always specify *mode* for writing.

Note that the file is always opened in binary mode. To open a compressed file in text mode, use `open()` (or wrap your **GzipFile** with an `io.TextIOWrapper`).

The *compresslevel* argument is an integer from 0 to 9 controlling the level of compression; 1 is fastest and produces the least compression, and 9 is slowest and produces the most compression. 0 is no compression. The default is 9.

The *mtime* argument is an optional numeric timestamp to be written to the last modification time field in the stream when compressing. It should only be provided in compression mode. If omitted or `None`, the current time is used. See the **mtime** attribute for more details.

Calling a **GzipFile** object's `close()` method does not close *fileobj*, since you might wish to append more material after the compressed data. This also allows you to pass an `io.BytesIO` object opened for writing as *fileobj*, and retrieve the resulting memory buffer using the `io.BytesIO` object's `getvalue()` method.

**GzipFile** supports the `io.BufferedIOBase` interface, including iteration and the `with` statement. Only the `truncate()` method isn't implemented.

**GzipFile** also provides the following method and attribute:

**peek(*n*)**

Read *n* uncompressed bytes without advancing the file position. At most one single read on the compressed stream is done to satisfy the call. The number of bytes returned may be more or less than requested.

### Note

While calling **peek()** does not change the file position of the **GzipFile**, it may change the position of the underlying file object (e.g. if the **GzipFile** was constructed with the *fileobj* parameter).

*New in version 3.2.*

**mtime**

When decompressing, the value of the last modification time field in the most recently read header may be read from this attribute, as an integer. The initial value before reading any headers is `None`.

All **gzip** compressed streams are required to contain this timestamp field. Some programs, such as **gunzip**, make use of the timestamp. The format is the same as the return value of **time.time()** and the **st\_mtime** attribute of the object returned by **os.stat()**.

**name**

The path to the gzip file on disk, as a **str** or **bytes**. Equivalent to the output of **os.fspath()** on the original input path, with no other normalization, resolution or expansion.

*Changed in version 3.1:* Support for the **with** statement was added, along with the *mtime* constructor argument and **mtime** attribute.

*Changed in version 3.2:* Support for zero-padded and unseekable files was added.

*Changed in version 3.3:* The `io.BufferedIOBase.read1()` method is now implemented.

*Changed in version 3.4:* Added support for the `'x'` and `'xb'` modes.

*Changed in version 3.5:* Added support for writing arbitrary `bytes-like objects`. The `read()` method now accepts an argument of `None`.

*Changed in version 3.6:* Accepts a `path-like object`.

*Deprecated since version 3.9:* Opening `GzipFile` for writing without specifying the `mode` argument is deprecated.

`gzip.compress(data, compresslevel=9, *, mtime=None)`

Compress the `data`, returning a `bytes` object containing the compressed data. `compresslevel` and `mtime` have the same meaning as in the `GzipFile` constructor above. When `mtime` is set to `0`, this function is equivalent to `zlib.compress()` with `wbits` set to `31`. The `zlib` function is faster.

*New in version 3.2.*

*Changed in version 3.8:* Added the `mtime` parameter for reproducible output.

*Changed in version 3.11:* Speed is improved by compressing all data at once instead of in a streamed fashion. Calls with `mtime` set to `0` are delegated to `zlib.compress()` for better speed.

`gzip.decompress(data)`

Decompress the `data`, returning a `bytes` object containing the uncompressed data. This function is capable of decompressing multi-member gzip data (multiple gzip blocks concatenated together). When the data is certain to contain

only one member the `zlib.decompress()` function with *wbits* set to 31 is faster.

*New in version 3.2.*

*Changed in version 3.11:* Speed is improved by decompressing members at once in memory instead of in a streamed fashion.

## Examples of usage

Example of how to read a compressed file:

```
import gzip
with gzip.open('/home/joe/file.txt.gz', 'rb') as f:
    file_content = f.read()
```

Example of how to create a compressed GZIP file:

```
import gzip
content = b"Lots of content here"
with gzip.open('/home/joe/file.txt.gz', 'wb') as f:
    f.write(content)
```

Example of how to GZIP compress an existing file:

```
import gzip
import shutil
with open('/home/joe/file.txt', 'rb') as f_in:
    with gzip.open('/home/joe/file.txt.gz', 'wb') as f_out:
        shutil.copyfileobj(f_in, f_out)
```

Example of how to GZIP compress a binary string:

```
import gzip
s_in = b"Lots of content here"
s_out = gzip.compress(s_in)
```

**See also**

**Module** `zlib`

The basic data compression module needed to support the **gzip** file format.

## Command Line Interface

The **gzip** module provides a simple command line interface to compress or decompress files.

Once executed the **gzip** module keeps the input file(s).

*Changed in version 3.8:* Add a new command line interface with a usage. By default, when you will execute the CLI, the default compression level is 6.

### Command line options

file

If *file* is not specified, read from **sys.stdin**.

--fast

Indicates the fastest compression method (less compression).

--best

Indicates the slowest compression method (best compression).

-d, --decompress

Decompress the given file.

-h, --help

Show the help message.

# bz2 — Support for bzip2 compression

**Source code:** [Lib/bz2.py](https://github.com/python/cpython/tree/3.11/Lib/bz2.py) [https://github.com/python/cpython/tree/3.11/Lib/bz2.py]

---

This module provides a comprehensive interface for compressing and decompressing data using the bzip2 compression algorithm.

The **bz2** module contains:

- The **open()** function and **BZ2File** class for reading and writing compressed files.
- The **BZ2Compressor** and **BZ2Decompressor** classes for incremental (de)compression.
- The **compress()** and **decompress()** functions for one-shot (de)compression.

## (De)compression of files

`bz2.open(filename, mode='rb', compresslevel=9, encoding=None, errors=None, newline=None)`

Open a bzip2-compressed file in binary or text mode, returning a [file object](#).

As with the constructor for **BZ2File**, the *filename* argument can be an actual filename (a **str** or **bytes** object), or an existing file object to read from or write to.

The *mode* argument can be any of `'r'`, `'rb'`, `'w'`, `'wb'`, `'x'`, `'xb'`, `'a'` or `'ab'` for binary mode, or `'rt'`, `'wt'`, `'xt'`, or `'at'` for text mode. The default is `'rb'`.

The *compresslevel* argument is an integer from 1 to 9, as for

the `BZ2File` constructor.

For binary mode, this function is equivalent to the `BZ2File` constructor: `BZ2File(filename, mode, compresslevel=compresslevel)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a `BZ2File` object is created, and wrapped in an `io.TextIOWrapper` instance with the specified encoding, error handling behavior, and line ending(s).

*New in version 3.3.*

*Changed in version 3.4:* The `'x'` (exclusive creation) mode was added.

*Changed in version 3.6:* Accepts a [path-like object](#).

```
class bz2.BZ2File(filename, mode='r', *, compresslevel=9)
```

Open a bzip2-compressed file in binary mode.

If *filename* is a `str` or `bytes` object, open the named file directly. Otherwise, *filename* should be a [file object](#), which will be used to read or write the compressed data.

The *mode* argument can be either `'r'` for reading (default), `'w'` for overwriting, `'x'` for exclusive creation, or `'a'` for appending. These can equivalently be given as `'rb'`, `'wb'`, `'xb'` and `'ab'` respectively.

If *filename* is a file object (rather than an actual file name), a mode of `'w'` does not truncate the file, and is instead equivalent to `'a'`.

If *mode* is `'w'` or `'a'`, *compresslevel* can be an integer between 1 and 9 specifying the level of compression: 1 produces the least compression, and 9 (default) produces the most compression.

If *mode* is `'r'`, the input file may be the concatenation of multiple compressed streams.

**BZ2File** provides all of the members specified by the **io.BufferedIOBase**, except for **detach()** and **truncate()**. Iteration and the **with** statement are supported.

**BZ2File** also provides the following method:

**peek([n])**

Return buffered data without advancing the file position. At least one byte of data will be returned (unless at EOF). The exact number of bytes returned is unspecified.

### Note

While calling **peek()** does not change the file position of the **BZ2File**, it may change the position of the underlying file object (e.g. if the **BZ2File** was constructed by passing a file object for *filename*).

*New in version 3.3.*

*Changed in version 3.1:* Support for the **with** statement was added.

*Changed in version 3.3:* The **fileno()**, **readable()**, **seekable()**, **writable()**, **readl()** and **readinto()** methods were added.

*Changed in version 3.3:* Support was added for *filename* being a **file object** instead of an actual filename.

*Changed in version 3.3:* The **'a'** (append) mode was added, along with support for reading multi-stream files.

*Changed in version 3.4:* The **'x'** (exclusive creation) mode was added.

*Changed in version 3.5:* The **read()** method now accepts an argument of **None**.

*Changed in version 3.6:* Accepts a [path-like object](#).

*Changed in version 3.9:* The *buffering* parameter has been removed. It was ignored and deprecated since Python 3.0. Pass an open file object to control how the file is opened.

The *compresslevel* parameter became keyword-only.

*Changed in version 3.10:* This class is thread unsafe in the face of multiple simultaneous readers or writers, just like its equivalent classes in [gzip](#) and [lzma](#) have always been.

## Incremental (de)compression

*class* bz2.BZ2Compressor(*compresslevel*=9)

Create a new compressor object. This object may be used to compress data incrementally. For one-shot compression, use the [compress\(\)](#) function instead.

*compresslevel*, if given, must be an integer between 1 and 9. The default is 9.

*compress*(*data*)

Provide data to the compressor object. Returns a chunk of compressed data if possible, or an empty byte string otherwise.

When you have finished providing data to the compressor, call the [flush\(\)](#) method to finish the compression process.

*flush*()

Finish the compression process. Returns the compressed data left in internal buffers.

The compressor object may not be used after this method has been called.

*class* bz2.BZ2Decompressor

Create a new decompressor object. This object may be used to decompress data incrementally. For one-shot compression, use the `decompress()` function instead.

### Note

This class does not transparently handle inputs containing multiple compressed streams, unlike `decompress()` and `BZ2File`. If you need to decompress a multi-stream input with `BZ2Decompressor`, you must use a new decompressor for each stream.

`decompress(data, max_length=-1)`

Decompress *data* (a bytes-like object), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to `decompress()`. The returned data should be concatenated with the output of any previous calls to `decompress()`.

If *max\_length* is nonnegative, returns at most *max\_length* bytes of decompressed data. If this limit is reached and further output can be produced, the `needs_input` attribute will be set to `False`. In this case, the next call to `decompress()` may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max\_length* bytes, or because *max\_length* was negative), the `needs_input` attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an `EOFError`. Any data found after the end of the stream is ignored and saved in the `unused_data` attribute.

*Changed in version 3.5:* Added the *max\_length* parameter.

True if the end-of-stream marker has been reached.

*New in version 3.3.*

`unused_data`

Data found after the end of the compressed stream.

If this attribute is accessed before the end of the stream has been reached, its value will be `b''`.

`needs_input`

False if the `decompress()` method can provide more decompressed data before requiring new uncompressed input.

*New in version 3.5.*

## One-shot (de)compression

`bz2.compress(data, compresslevel=9)`

Compress *data*, a [bytes-like object](#).

*compresslevel*, if given, must be an integer between 1 and 9. The default is 9.

For incremental compression, use a [BZ2Compressor](#) instead.

`bz2.decompress(data)`

Decompress *data*, a [bytes-like object](#).

If *data* is the concatenation of multiple compressed streams, decompress all of the streams.

For incremental decompression, use a [BZ2Decompressor](#) instead.

*Changed in version 3.3:* Support for multi-stream inputs was added.

# Examples of usage

Below are some examples of typical usage of the **bz2** module.

Using **compress()** and **decompress()** to demonstrate round-trip compression:

```
>>> import bz2
>>> data = b"""\
... Donec rhoncus quis sapien sit amet molestie. Fusce s
... nec ullamcorper. Nam rutrum pretium placerat. Aliqua
... sit amet cursus ante. In interdum laoreet mi, sit am
... pulvinar a. Nam gravida euismod magna, non varius ju
... Aliquam pharetra lacus non risus vehicula rutrum. Ma
... felis. Pellentesque semper nunc sit amet nibh ullamc
... dolor luctus. Curabitur lacinia mi ornare consectetur
>>> c = bz2.compress(data)
>>> len(data) / len(c)  # Data compression ratio
1.513595166163142
>>> d = bz2.decompress(c)
>>> data == d  # Check equality to original object after
True
```

Using **BZ2Compressor** for incremental compression:

```
>>> import bz2
>>> def gen_data(chunks=10, chunksize=1000):
...     """Yield incremental blocks of chunksize bytes."""
...     for _ in range(chunks):
...         yield b"z" * chunksize
...
>>> comp = bz2.BZ2Compressor()
>>> out = b""
>>> for chunk in gen_data():
...     # Provide data to the compressor object
...     out = out + comp.compress(chunk)
...
>>> # Finish the compression process. Call this once you
>>> # finished providing data to the compressor.
```

```
>>> out = out + comp.flush()
```

The example above uses a very “nonrandom” stream of data (a stream of `b"z"` chunks). Random data tends to compress poorly, while ordered, repetitive data usually yields a high compression ratio.

Writing and reading a bzip2-compressed file in binary mode:

```
>>> import bz2
>>> data = b"""\
... Donec rhoncus quis sapien sit amet molestie. Fusce s
... nec ullamcorper. Nam rutrum pretium placerat. Aliqua
... sit amet cursus ante. In interdum laoreet mi, sit am
... pulvinar a. Nam gravida euismod magna, non varius ju
... Aliquam pharetra lacus non risus vehicula rutrum. Ma
... felis. Pellentesque semper nunc sit amet nibh ullamc
... dolor luctus. Curabitur lacinia mi ornare consectetur
>>> with bz2.open("myfile.bz2", "wb") as f:
...     # Write compressed data to file
...     unused = f.write(data)
>>> with bz2.open("myfile.bz2", "rb") as f:
...     # Decompress data from file
...     content = f.read()
>>> content == data # Check equality to original object
True
```

# lzma — Compression using the LZMA algorithm

*New in version 3.3.*

**Source code:** [Lib/lzma.py](https://github.com/python/cpython/tree/3.11/Lib/lzma.py) [https://github.com/python/cpython/tree/3.11/Lib/lzma.py]

---

This module provides classes and convenience functions for compressing and decompressing data using the LZMA compression algorithm. Also included is a file interface supporting the `.xz` and legacy `.lzma` file formats used by the `xz` utility, as well as raw compressed streams.

The interface provided by this module is very similar to that of the `bz2` module. Note that `LZMAFile` and `bz2.BZ2File` are *not* thread-safe, so if you need to use a single `LZMAFile` instance from multiple threads, it is necessary to protect it with a lock.

*exception* `lzma.LZMAError`

This exception is raised when an error occurs during compression or decompression, or while initializing the compressor/decompressor state.

## Reading and writing compressed files

```
lzma.open(filename, mode='rb', *, format=None, check=-1,
preset=None, filters=None, encoding=None, errors=None,
newline=None)
```

Open an LZMA-compressed file in binary or text mode, returning a [file object](#).

The *filename* argument can be either an actual file name

(given as a [str](#), [bytes](#) or [path-like](#) object), in which case the named file is opened, or it can be an existing file object to read from or write to.

The *mode* argument can be any of "r", "rb", "w", "wb", "x", "xb", "a" or "ab" for binary mode, or "rt", "wt", "xt", or "at" for text mode. The default is "rb".

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for [LZMADecompressor](#). In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for [LZMACompressor](#).

For binary mode, this function is equivalent to the [LZMAFile](#) constructor: `LZMAFile(filename, mode, ...)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a [LZMAFile](#) object is created, and wrapped in an [io.TextIOWrapper](#) instance with the specified encoding, error handling behavior, and line ending(s).

*Changed in version 3.4:* Added support for the "x", "xb" and "xt" modes.

*Changed in version 3.6:* Accepts a [path-like object](#).

```
class lzma.LZMAFile(filename=None, mode='r', *, format=None,
check=-1, preset=None, filters=None)
```

Open an LZMA-compressed file in binary mode.

An [LZMAFile](#) can wrap an already-open [file object](#), or operate directly on a named file. The *filename* argument specifies either the file object to wrap, or the name of the file to open (as a [str](#), [bytes](#) or [path-like](#) object). When wrapping an existing file object, the wrapped file will not be closed when the [LZMAFile](#) is closed.

The *mode* argument can be either "r" for reading (default), "w" for overwriting, "x" for exclusive creation, or "a" for appending. These can equivalently be given as "rb", "wb", "xb" and "ab" respectively.

If *filename* is a file object (rather than an actual file name), a mode of "w" does not truncate the file, and is instead equivalent to "a".

When opening a file for reading, the input file may be the concatenation of multiple separate compressed streams. These are transparently decoded as a single logical stream.

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for [LZMADecompressor](#). In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for [LZMACompressor](#).

[LZMAFile](#) supports all the members specified by [io.BufferedIOBase](#), except for `detach()` and `truncate()`. Iteration and the `with` statement are supported.

The following method is also provided:

`peek(size = - 1)`

Return buffered data without advancing the file position. At least one byte of data will be returned, unless EOF has been reached. The exact number of bytes returned is unspecified (the *size* argument is ignored).

### Note

While calling `peek()` does not change the file position of the [LZMAFile](#), it may change the position of the underlying file object (e.g. if the

**LZMAFile** was constructed by passing a file object for *filename*).

*Changed in version 3.4:* Added support for the "x" and "xb" modes.

*Changed in version 3.5:* The **read()** method now accepts an argument of `None`.

*Changed in version 3.6:* Accepts a [path-like object](#).

## Compressing and decompressing data in memory

```
class lzma.LZMACompressor(format=FORMAT_XZ, check=-1,
preset=None, filters=None)
```

Create a compressor object, which can be used to compress data incrementally.

For a more convenient way of compressing a single chunk of data, see **compress()**.

The *format* argument specifies what container format should be used. Possible values are:

- **FORMAT\_XZ:** The `.xz` container format.  
This is the default format.
- **FORMAT\_ALONE:** The legacy `.lzma` container format.  
This format is more limited than `.xz` – it does not support integrity checks or multiple filters.
- **FORMAT\_RAW:** A raw data stream, not using any container format.  
This format specifier does not support integrity checks, and requires that you always specify a custom filter chain (for both compression and

decompression). Additionally, data compressed in this manner cannot be decompressed using **FORMAT\_AUTO** (see [LZMADecompressor](#)).

The *check* argument specifies the type of integrity check to include in the compressed data. This check is used when decompressing, to ensure that the data has not been corrupted. Possible values are:

- **CHECK\_NONE**: No integrity check. This is the default (and the only acceptable value) for **FORMAT\_ALONE** and **FORMAT\_RAW**.
- **CHECK\_CRC32**: 32-bit Cyclic Redundancy Check.
- **CHECK\_CRC64**: 64-bit Cyclic Redundancy Check. This is the default for **FORMAT\_XZ**.
- **CHECK\_SHA256**: 256-bit Secure Hash Algorithm.

If the specified check is not supported, an [LZMAError](#) is raised.

The compression settings can be specified either as a preset compression level (with the *preset* argument), or in detail as a custom filter chain (with the *filters* argument).

The *preset* argument (if provided) should be an integer between 0 and 9 (inclusive), optionally OR-ed with the constant **PRESET\_EXTREME**. If neither *preset* nor *filters* are given, the default behavior is to use **PRESET\_DEFAULT** (preset level 6). Higher presets produce smaller output, but make the compression process slower.

## Note

In addition to being more CPU-intensive, compression with higher presets also requires much more memory (and produces output that needs more memory to decompress). With preset 9 for example, the overhead for an [LZMACompressor](#) object can be as high as 800 MiB. For this reason, it is generally best to stick with the default preset.

The *filters* argument (if provided) should be a filter chain specifier. See [Specifying custom filter chains](#) for details.

`compress(data)`

Compress *data* (a [bytes](#) object), returning a [bytes](#) object containing compressed data for at least part of the input. Some of *data* may be buffered internally, for use in later calls to `compress()` and `flush()`. The returned data should be concatenated with the output of any previous calls to `compress()`.

`flush()`

Finish the compression process, returning a [bytes](#) object containing any data stored in the compressor's internal buffers.

The compressor cannot be used after this method has been called.

`class lzma.LZMADecompressor(format=FORMAT_AUTO,  
memlimit=None, filters=None)`

Create a decompressor object, which can be used to decompress data incrementally.

For a more convenient way of decompressing an entire compressed stream at once, see `decompress()`.

The *format* argument specifies the container format that should be used. The default is `FORMAT_AUTO`, which can decompress both `.xz` and `.lzma` files. Other possible values are `FORMAT_XZ`, `FORMAT_ALONE`, and `FORMAT_RAW`.

The *memlimit* argument specifies a limit (in bytes) on the amount of memory that the decompressor can use. When this argument is used, decompression will fail with an [LZMAError](#) if it is not possible to decompress the input within the given memory limit.

The *filters* argument specifies the filter chain that was used to

create the stream being decompressed. This argument is required if *format* is **FORMAT\_RAW**, but should not be used for other formats. See [Specifying custom filter chains](#) for more information about filter chains.

## Note

This class does not transparently handle inputs containing multiple compressed streams, unlike [decompress\(\)](#) and [LZMAFile](#). To decompress a multi-stream input with [LZMADecompressor](#), you must create a new decompressor for each stream.

`decompress(data, max_length=-1)`

Decompress *data* (a [bytes-like object](#)), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to [decompress\(\)](#). The returned data should be concatenated with the output of any previous calls to [decompress\(\)](#).

If *max\_length* is nonnegative, returns at most *max\_length* bytes of decompressed data. If this limit is reached and further output can be produced, the [needs\\_input](#) attribute will be set to `False`. In this case, the next call to [decompress\(\)](#) may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max\_length* bytes, or because *max\_length* was negative), the [needs\\_input](#) attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an [EOFError](#). Any data found after the end of the stream is ignored and saved in the [unused\\_data](#) attribute.

*Changed in version 3.5:* Added the *max\_length* parameter.

check

The ID of the integrity check used by the input stream. This may be **CHECK\_UNKNOWN** until enough of the input has been decoded to determine what integrity check it uses.

eof

True if the end-of-stream marker has been reached.

unused\_data

Data found after the end of the compressed stream.

Before the end of the stream is reached, this will be `b""`.

needs\_input

False if the `decompress()` method can provide more decompressed data before requiring new uncompressed input.

*New in version 3.5.*

`lzma.compress(data, format=FORMAT_XZ, check=-1, preset=None, filters=None)`

Compress *data* (a **bytes** object), returning the compressed data as a **bytes** object.

See **LZMACompressor** above for a description of the *format*, *check*, *preset* and *filters* arguments.

`lzma.decompress(data, format=FORMAT_AUTO, memlimit=None, filters=None)`

Decompress *data* (a **bytes** object), returning the uncompressed data as a **bytes** object.

If *data* is the concatenation of multiple distinct compressed streams, decompress all of these streams, and return the concatenation of the results.

See [LZMADecompressor](#) above for a description of the *format*, *memlimit* and *filters* arguments.

## Miscellaneous

`lzma.is_check_supported(check)`

Return `True` if the given integrity check is supported on this system.

**CHECK\_NONE** and **CHECK\_CRC32** are always supported.  
**CHECK\_CRC64** and **CHECK\_SHA256** may be unavailable if you are using a version of **liblzma** that was compiled with a limited feature set.

## Specifying custom filter chains

A filter chain specifier is a sequence of dictionaries, where each dictionary contains the ID and options for a single filter. Each dictionary must contain the key `"id"`, and may contain additional keys to specify filter-dependent options. Valid filter IDs are as follows:

- Compression filters:
  - **FILTER\_LZMA1** (for use with **FORMAT\_ALONE**)
  - **FILTER\_LZMA2** (for use with **FORMAT\_XZ** and **FORMAT\_RAW**)
- Delta filter:
  - **FILTER\_DELTA**
- Branch-Call-Jump (BCJ) filters:
  - **FILTER\_X86**
  - **FILTER\_IA64**
  - **FILTER\_ARM**
  - **FILTER\_ARMTHUMB**
  - **FILTER\_POWERPC**
  - **FILTER\_SPARC**

A filter chain can consist of up to 4 filters, and cannot be empty. The last filter in the chain must be a compression filter, and any other filters must be delta or BCJ filters.

Compression filters support the following options (specified as additional entries in the dictionary representing the filter):

- `preset`: A compression preset to use as a source of default values for options that are not specified explicitly.
- `dict_size`: Dictionary size in bytes. This should be between 4 KiB and 1.5 GiB (inclusive).
- `lc`: Number of literal context bits.
- `lp`: Number of literal position bits. The sum `lc + lp` must be at most 4.
- `pb`: Number of position bits; must be at most 4.
- `mode`: **MODE\_FAST** or **MODE\_NORMAL**.
- `nice_len`: What should be considered a “nice length” for a match. This should be 273 or less.
- `mf`: What match finder to use – **MF\_HC3**, **MF\_HC4**, **MF\_BT2**, **MF\_BT3**, or **MF\_BT4**.
- `depth`: Maximum search depth used by match finder. 0 (default) means to select automatically based on other filter options.

The delta filter stores the differences between bytes, producing more repetitive input for the compressor in certain circumstances. It supports one option, `dist`. This indicates the distance between bytes to be subtracted. The default is 1, i.e. take the differences between adjacent bytes.

The BCJ filters are intended to be applied to machine code. They convert relative branches, calls and jumps in the code to use absolute addressing, with the aim of increasing the redundancy that can be exploited by the compressor. These filters support one option, `start_offset`. This specifies the address that should be mapped to the beginning of the input data. The default is 0.

# Examples

Reading in a compressed file:

```
import lzma
with lzma.open("file.xz") as f:
    file_content = f.read()
```

Creating a compressed file:

```
import lzma
data = b"Insert Data Here"
with lzma.open("file.xz", "w") as f:
    f.write(data)
```

Compressing data in memory:

```
import lzma
data_in = b"Insert Data Here"
data_out = lzma.compress(data_in)
```

Incremental compression:

```
import lzma
lzc = lzma.LZMACompressor()
out1 = lzc.compress(b"Some data\n")
out2 = lzc.compress(b"Another piece of data\n")
out3 = lzc.compress(b"Even more data\n")
out4 = lzc.flush()
# Concatenate all the partial results:
result = b"".join([out1, out2, out3, out4])
```

Writing compressed data to an already-open file:

```
import lzma
with open("file.xz", "wb") as f:
    f.write(b"This data will not be compressed\n")
    with lzma.open(f, "w") as lzf:
        lzf.write(b"This *will* be compressed\n")
    f.write(b"Not compressed\n")
```

Creating a compressed file using a custom filter chain:

```
import lzma
my_filters = [
    {"id": lzma.FILTER_DELTA, "dist": 5},
    {"id": lzma.FILTER_LZMA2, "preset": 7 | lzma.PRESET_
]
with lzma.open("file.xz", "w", filters=my_filters) as f:
    f.write(b"blah blah blah")
```

# zipfile — Work with ZIP archives

**Source code:** [Lib/zipfile.py](#) [<https://github.com/python/cpython/tree/3.11/Lib/zipfile.py>]

---

The ZIP file format is a common archive and compression standard. This module provides tools to create, read, write, append, and list a ZIP file. Any advanced use of this module will require an understanding of the format, as defined in [PKZIP Application Note](https://pkware.cachefly.net/webdocs/casestudies/APPNOTE.TXT) [<https://pkware.cachefly.net/webdocs/casestudies/APPNOTE.TXT>].

This module does not currently handle multi-disk ZIP files. It can handle ZIP files that use the ZIP64 extensions (that is ZIP files that are more than 4 GiB in size). It supports decryption of encrypted files in ZIP archives, but it currently cannot create an encrypted file. Decryption is extremely slow as it is implemented in native Python rather than C.

The module defines the following items:

*exception* `zipfile.BadZipFile`

The error raised for bad ZIP files.

*New in version 3.2.*

*exception* `zipfile.BadZipfile`

Alias of `BadZipFile`, for compatibility with older Python versions.

*Deprecated since version 3.2.*

*exception* `zipfile.LargeZipFile`

The error raised when a ZIP file would require ZIP64

functionality but that has not been enabled.

`class zipfile.ZipFile`

The class for reading and writing ZIP files. See section [ZipFile Objects](#) for constructor details.

`class zipfile.Path`

Class that implements a subset of the interface provided by [pathlib.Path](#), including the full [importlib.resources.abc.Traversable](#) interface.

*New in version 3.8.*

`class zipfile.PyZipFile`

Class for creating ZIP archives containing Python libraries.

`class zipfile.ZipInfo(filename = 'NoName', date_time = (1980, 1, 1, 0, 0, 0))`

Class used to represent information about a member of an archive. Instances of this class are returned by the [getinfo\(\)](#) and [infolist\(\)](#) methods of [ZipFile](#) objects. Most users of the [zipfile](#) module will not need to create these, but only use those created by this module. *filename* should be the full name of the archive member, and *date\_time* should be a tuple containing six fields which describe the time of the last modification to the file; the fields are described in section [ZipInfo Objects](#).

`zipfile.is_zipfile(filename)`

Returns `True` if *filename* is a valid ZIP file based on its magic number, otherwise returns `False`. *filename* may be a file or file-like object too.

*Changed in version 3.1:* Support for file and file-like objects.

`zipfile.ZIP_STORED`

The numeric constant for an uncompressed archive member.

zipfile.ZIP\_DEFLATED

The numeric constant for the usual ZIP compression method.  
This requires the [zlib](#) module.

zipfile.ZIP\_BZIP2

The numeric constant for the BZIP2 compression method.  
This requires the [bz2](#) module.

*New in version 3.3.*

zipfile.ZIP\_LZMA

The numeric constant for the LZMA compression method.  
This requires the [lzma](#) module.

*New in version 3.3.*

### **Note**

The ZIP file format specification has included support for bzip2 compression since 2001, and for LZMA compression since 2006. However, some tools (including older Python releases) do not support these compression methods, and may either refuse to process the ZIP file altogether, or fail to extract individual files.

## **ZipFile Objects**

```
class zipfile.ZipFile(file, mode='r', compression=ZIP_STORED,
allowZip64=True, compresslevel=None, *, strict_timestamps=True,
metadata_encoding=None)
```

Open a ZIP file, where *file* can be a path to a file (a string), a file-like object or a [path-like object](#).

The *mode* parameter should be `'r'` to read an existing file, `'w'` to truncate and write a new file, `'a'` to append to an existing file, or `'x'` to exclusively create and write a new file. If *mode* is `'x'` and *file* refers to an existing file, a [FileExistsError](#) will be raised. If *mode* is `'a'` and *file* refers to an existing ZIP file, then additional files are added to it. If *file* does not refer to a ZIP file, then a new ZIP archive is appended to the file. This is meant for adding a ZIP archive to another file (such as `python.exe`). If *mode* is `'a'` and the file does not exist at all, it is created. If *mode* is `'r'` or `'a'`, the file should be seekable.

*compression* is the ZIP compression method to use when writing the archive, and should be [ZIP\\_STORED](#), [ZIP\\_DEFLATED](#), [ZIP\\_BZIP2](#) or [ZIP\\_LZMA](#); unrecognized values will cause [NotImplementedError](#) to be raised. If [ZIP\\_DEFLATED](#), [ZIP\\_BZIP2](#) or [ZIP\\_LZMA](#) is specified but the corresponding module ([zlib](#), [bz2](#) or [lzma](#)) is not available, [RuntimeError](#) is raised. The default is [ZIP\\_STORED](#).

If *allowZip64* is `True` (the default) `zipfile` will create ZIP files that use the ZIP64 extensions when the `zipfile` is larger than 4 GiB. If it is `false` [zipfile](#) will raise an exception when the ZIP file would require ZIP64 extensions.

The *compresslevel* parameter controls the compression level to use when writing files to the archive. When using [ZIP\\_STORED](#) or [ZIP\\_LZMA](#) it has no effect. When using [ZIP\\_DEFLATED](#) integers 0 through 9 are accepted (see [zlib](#) for more information). When using [ZIP\\_BZIP2](#) integers 1 through 9 are accepted (see [bz2](#) for more information).

The *strict\_timestamps* argument, when set to `False`, allows to zip files older than 1980-01-01 at the cost of setting the timestamp to 1980-01-01. Similar behavior occurs with files newer than 2107-12-31, the timestamp is also set to the limit.

When mode is `'r'`, *metadata\_encoding* may be set to the name of a codec, which will be used to decode metadata such as the names of members and ZIP comments.

If the file is created with mode `'w'`, `'x'` or `'a'` and then **closed** without adding any files to the archive, the appropriate ZIP structures for an empty archive will be written to the file.

ZipFile is also a context manager and therefore supports the **with** statement. In the example, *myzip* is closed after the **with** statement's suite is finished—even if an exception occurs:

```
with ZipFile('spam.zip', 'w') as myzip:
    myzip.write('eggs.txt')
```

## Note

*metadata\_encoding* is an instance-wide setting for the ZipFile. It is not currently possible to set this on a per-member basis.

This attribute is a workaround for legacy implementations which produce archives with names in the current locale encoding or code page (mostly on Windows). According to the .ZIP standard, the encoding of metadata may be specified to be either IBM code page (default) or UTF-8 by a flag in the archive header. That flag takes precedence over *metadata\_encoding*, which is a Python-specific extension.

*New in version 3.2:* Added the ability to use **ZipFile** as a context manager.

*Changed in version 3.3:* Added support for **bzip2** and **lzma**

compression.

*Changed in version 3.4:* ZIP64 extensions are enabled by default.

*Changed in version 3.5:* Added support for writing to unseekable streams. Added support for the 'x' mode.

*Changed in version 3.6:* Previously, a plain `RuntimeError` was raised for unrecognized compression values.

*Changed in version 3.6.2:* The *file* parameter accepts a [path-like object](#).

*Changed in version 3.7:* Add the *compresslevel* parameter.

*New in version 3.8:* The *strict\_timestamps* keyword-only argument

*Changed in version 3.11:* Added support for specifying member name encoding for reading metadata in the zipfile's directory and file headers.

## `ZipFile.close()`

Close the archive file. You must call `close()` before exiting your program or essential records will not be written.

## `ZipFile.getinfo(name)`

Return a `ZipInfo` object with information about the archive member *name*. Calling `getinfo()` for a name not currently contained in the archive will raise a `KeyError`.

## `ZipFile.infolist()`

Return a list containing a `ZipInfo` object for each member of the archive. The objects are in the same order as their entries in the actual ZIP file on disk if an existing archive was opened.

## `ZipFile.namelist()`

Return a list of archive members by name.

`ZipFile.open(name, mode='r', pwd=None, *, force_zip64=False)`

Access a member of the archive as a binary file-like object. *name* can be either the name of a file within the archive or a `ZipInfo` object. The *mode* parameter, if included, must be `'r'` (the default) or `'w'`. *pwd* is the password used to decrypt encrypted ZIP files as a `bytes` object.

`open()` is also a context manager and therefore supports the `with` statement:

```
with ZipFile('spam.zip') as myzip:
    with myzip.open('eggs.txt') as myfile:
        print(myfile.read())
```

With *mode* `'r'` the file-like object (`ZipExtFile`) is read-only and provides the following methods: `read()`, `readline()`, `readlines()`, `seek()`, `tell()`, `__iter__()`, `__next__()`. These objects can operate independently of the `ZipFile`.

With *mode* `'w'`, a writable file handle is returned, which supports the `write()` method. While a writable file handle is open, attempting to read or write other files in the ZIP file will raise a `ValueError`.

When writing a file, if the file size is not known in advance but may exceed 2 GiB, pass `force_zip64=True` to ensure that the header format is capable of supporting large files. If the file size is known in advance, construct a `ZipInfo` object with `file_size` set, and use that as the *name* parameter.

## Note

The `open()`, `read()` and `extract()` methods can take a filename or a `ZipInfo` object. You will appreciate this when trying to read a ZIP file that contains members with duplicate names.

*Changed in version 3.6:* Removed support of `mode='U'`. Use `io.TextIOWrapper` for reading compressed text files in `universal newlines` mode.

*Changed in version 3.6:* `ZipFile.open()` can now be used to write files into the archive with the `mode='w'` option.

*Changed in version 3.6:* Calling `open()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.extract(member, path=None, pwd=None)`

Extract a member from the archive to the current working directory; *member* must be its full name or a `ZipInfo` object. Its file information is extracted as accurately as possible. *path* specifies a different directory to extract to. *member* can be a filename or a `ZipInfo` object. *pwd* is the password used for encrypted files as a `bytes` object.

Returns the normalized path created (a directory or new file).

### Note

If a member filename is an absolute path, a drive/UNC sharepoint and leading (back)slashes will be stripped, e.g.: `///foo/bar` becomes `foo/bar` on Unix, and `C:\foo\bar` becomes `foo\bar` on Windows. And all `".."` components in a member filename will be removed, e.g.: `../../../../foo../../../../ba..r` becomes `foo../ba..r`. On Windows illegal characters (`:`, `<`, `>`, `|`, `"`, `?`, and `*`) replaced by underscore (`_`).

*Changed in version 3.6:* Calling `extract()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

*Changed in version 3.6.2:* The *path* parameter accepts a `path-like object`.

`ZipFile.extractall(path=None, members=None, pwd=None)`

Extract all members from the archive to the current working directory. *path* specifies a different directory to extract to. *members* is optional and must be a subset of the list returned by `namelist()`. *pwd* is the password used for encrypted files as a `bytes` object.

### Warning

Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `". . "`. This module attempts to prevent that. See `extract()` note.

*Changed in version 3.6:* Calling `extractall()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

*Changed in version 3.6.2:* The *path* parameter accepts a `path-like object`.

### `ZipFile.printdir()`

Print a table of contents for the archive to `sys.stdout`.

### `ZipFile.setpassword(pwd)`

Set *pwd* (a `bytes` object) as default password to extract encrypted files.

### `ZipFile.read(name, pwd=None)`

Return the bytes of the file *name* in the archive. *name* is the name of the file in the archive, or a `ZipInfo` object. The archive must be open for read or append. *pwd* is the password used for encrypted files as a `bytes` object and, if specified, overrides the default password set with `setpassword()`. Calling `read()` on a `ZipFile` that uses a compression method other than `ZIP_STORED`, `ZIP_DEFLATED`, `ZIP_BZIP2` or `ZIP_LZMA` will raise a `NotImplementedError`. An error will also be raised if the corresponding compression module is

not available.

*Changed in version 3.6:* Calling `read()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

## `ZipFile.testzip()`

Read all the files in the archive and check their CRC's and file headers. Return the name of the first bad file, or else return `None`.

*Changed in version 3.6:* Calling `testzip()` on a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

## `ZipFile.write(filename, arcname=None, compress_type=None, compresslevel=None)`

Write the file named *filename* to the archive, giving it the archive name *arcname* (by default, this will be the same as *filename*, but without a drive letter and with leading path separators removed). If given, *compress\_type* overrides the value given for the *compression* parameter to the constructor for the new entry. Similarly, *compresslevel* will override the constructor if given. The archive must be open with mode `'w'`, `'x'` or `'a'`.

### Note

The ZIP file standard historically did not specify a metadata encoding, but strongly recommended CP437 (the original IBM PC encoding) for interoperability. Recent versions allow use of UTF-8 (only). In this module, UTF-8 will automatically be used to write the member names if they contain any non-ASCII characters. It is not possible to write member names in any encoding other than ASCII or UTF-8.

### Note

Archive names should be relative to the archive root, that is, they should not start with a path separator.

### Note

If `arcname` (or `filename`, if `arcname` is not given) contains a null byte, the name of the file in the archive will be truncated at the null byte.

### Note

A leading slash in the filename may lead to the archive being impossible to open in some zip programs on Windows systems.

*Changed in version 3.6:* Calling `write()` on a `ZipFile` created with mode `'r'` or a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.writestr(zinfo_or_arcname, data, compress_type=None, compresslevel=None)`

Write a file into the archive. The contents is *data*, which may be either a `str` or a `bytes` instance; if it is a `str`, it is encoded as UTF-8 first. *zinfo\_or\_arcname* is either the file name it will be given in the archive, or a `ZipInfo` instance. If it's an instance, at least the filename, date, and time must be given. If it's a name, the date and time is set to the current date and time. The archive must be opened with mode `'w'`, `'x'` or `'a'`.

If given, *compress\_type* overrides the value given for the *compression* parameter to the constructor for the new entry, or in the *zinfo\_or\_arcname* (if that is a `ZipInfo` instance). Similarly, *compresslevel* will override the constructor if given.

### Note

When passing a `ZipInfo` instance as the *zinfo\_or\_arcname* parameter, the compression method used will be that

specified in the `compress_type` member of the given `ZipInfo` instance. By default, the `ZipInfo` constructor sets this member to `ZIP_STORED`.

*Changed in version 3.2:* The `compress_type` argument.

*Changed in version 3.6:* Calling `writestr()` on a `ZipFile` created with mode `'r'` or a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.mkdir(zinfo_or_directory, mode=511)`

Create a directory inside the archive. If `zinfo_or_directory` is a string, a directory is created inside the archive with the mode that is specified in the `mode` argument. If, however, `zinfo_or_directory` is a `ZipInfo` instance then the `mode` argument is ignored.

The archive must be opened with mode `'w'`, `'x'` or `'a'`.

*New in version 3.11.*

The following data attributes are also available:

`ZipFile.filename`

Name of the ZIP file.

`ZipFile.debug`

The level of debug output to use. This may be set from `0` (the default, no output) to `3` (the most output). Debugging information is written to `sys.stdout`.

`ZipFile.comment`

The comment associated with the ZIP file as a `bytes` object. If assigning a comment to a `ZipFile` instance created with mode `'w'`, `'x'` or `'a'`, it should be no longer than 65535 bytes. Comments longer than this will be truncated.

## Path Objects

`class zipfile.Path(root, at= "")`

Construct a Path object from a `root` zipfile (which may be a `ZipFile` instance or `file` suitable for passing to the `ZipFile` constructor).

`at` specifies the location of this Path within the zipfile, e.g. 'dir/file.txt', 'dir/', or '. Defaults to the empty string, indicating the root.

Path objects expose the following features of `pathlib.Path` objects:

Path objects are traversable using the `/` operator or `joinpath`.

`Path.name`

The final path component.

`Path.open(mode='r', *, pwd, **)`

Invoke `ZipFile.open()` on the current path. Allows opening for read or write, text or binary through supported modes: 'r', 'w', 'rb', 'wb'. Positional and keyword arguments are passed through to `io.TextIOWrapper` when opened as text and ignored otherwise. `pwd` is the `pwd` parameter to `ZipFile.open()`.

*Changed in version 3.9:* Added support for text and binary modes for open. Default mode is now text.

*Changed in version 3.11.2:* The `encoding` parameter can be supplied as a positional argument without causing a `TypeError`. As it could in 3.9. Code needing to be compatible with unpatched 3.10 and 3.11 versions must pass all `io.TextIOWrapper` arguments, `encoding` included, as keywords.

`Path.iterdir()`

Enumerate the children of the current directory.

`Path.is_dir()`

Return `True` if the current context references a directory.

### `Path.is_file()`

Return `True` if the current context references a file.

### `Path.exists()`

Return `True` if the current context references a file or directory in the zip file.

### `Path.suffix`

The file extension of the final component.

*New in version 3.11:* Added `Path.suffix` property.

### `Path.stem`

The final path component, without its suffix.

*New in version 3.11:* Added `Path.stem` property.

### `Path.suffixes`

A list of the path's file extensions.

*New in version 3.11:* Added `Path.suffixes` property.

### `Path.read_text(*, **)`

Read the current file as unicode text. Positional and keyword arguments are passed through to `io.TextIOWrapper` (except `buffer`, which is implied by the context).

*Changed in version 3.11.2:* The `encoding` parameter can be supplied as a positional argument without causing a `TypeError`. As it could in 3.9. Code needing to be compatible with unpatched 3.10 and 3.11 versions must pass all `io.TextIOWrapper` arguments, `encoding` included, as keywords.

### `Path.read_bytes()`

Read the current file as bytes.

`Path.joinpath(*other)`

Return a new `Path` object with each of the *other* arguments joined. The following are equivalent:

```
>>> Path(...).joinpath('child').joinpath('grandchild')
>>> Path(...).joinpath('child', 'grandchild')
>>> Path(...) / 'child' / 'grandchild'
```

*Changed in version 3.10:* Prior to 3.10, `joinpath` was undocumented and accepted exactly one parameter.

The [zip](https://pypi.org/project/zip/) [https://pypi.org/project/zip/] project provides backports of the latest path object functionality to older Pythons. Use `zip.Path` in place of `zipfile.Path` for early access to changes.

## PyZipFile Objects

The `PyZipFile` constructor takes the same parameters as the `ZipFile` constructor, and one additional parameter, *optimize*.

```
class zipfile.PyZipFile(file, mode='r', compression=ZIP_STORED,
allowZip64=True, optimize=-1)
```

*New in version 3.2:* The *optimize* parameter.

*Changed in version 3.4:* ZIP64 extensions are enabled by default.

Instances have one method in addition to those of `ZipFile` objects:

```
writepy(pathname, basename="", filterfunc=None)
```

Search for files `*.py` and add the corresponding file to the archive.

If the *optimize* parameter to `PyZipFile` was not given or `-1`, the corresponding file is a `*.pyc` file, compiling if necessary.

If the *optimize* parameter to `PyZipFile` was 0, 1 or 2, only files with that optimization level (see `compile()`) are added to the archive, compiling if necessary.

If *pathname* is a file, the filename must end with `.py`, and just the (corresponding `*.pyc`) file is added at the top level (no path information). If *pathname* is a file that does not end with `.py`, a `RuntimeError` will be raised. If it is a directory, and the directory is not a package directory, then all the files `*.pyc` are added at the top level. If the directory is a package directory, then all `*.pyc` are added under the package name as a file path, and if any subdirectories are package directories, all of these are added recursively in sorted order.

*basename* is intended for internal use only.

*filterfunc*, if given, must be a function taking a single string argument. It will be passed each path (including each individual full file path) before it is added to the archive. If *filterfunc* returns a false value, the path will not be added, and if it is a directory its contents will be ignored. For example, if our test files are all either in test directories or start with the string `test_`, we can use a *filterfunc* to exclude them:

```
>>> zf = PyZipFile('myprog.zip')
>>> def notests(s):
...     fn = os.path.basename(s)
...     return (not (fn == 'test' or fn.startswith('test_')))
>>> zf.writepy('myprog', filterfunc=notests)
```

The `writepy()` method makes archives with file names like this:

```
string.pyc                # Top level name
test/__init__.pyc         # Package directory
test/testall.pyc          # Module test.testall
test/bogus/__init__.pyc   # Subpackage directory
```

```
test/bogus/myfile.pyc # Submodule test.k
```

*New in version 3.4:* The `filterfunc` parameter.

*Changed in version 3.6.2:* The `pathname` parameter accepts a [path-like object](#).

*Changed in version 3.7:* Recursion sorts directory entries.

## ZipInfo Objects

Instances of the `ZipInfo` class are returned by the `getinfo()` and `infolist()` methods of `ZipFile` objects. Each object stores information about a single member of the ZIP archive.

There is one classmethod to make a `ZipInfo` instance for a filesystem file:

```
classmethod ZipInfo.from_file(filename, arcname=None, *,
strict_timestamps=True)
```

Construct a `ZipInfo` instance for a file on the filesystem, in preparation for adding it to a zip file.

`filename` should be the path to a file or directory on the filesystem.

If `arcname` is specified, it is used as the name within the archive. If `arcname` is not specified, the name will be the same as `filename`, but with any drive letter and leading path separators removed.

The `strict_timestamps` argument, when set to `False`, allows to zip files older than 1980-01-01 at the cost of setting the timestamp to 1980-01-01. Similar behavior occurs with files newer than 2107-12-31, the timestamp is also set to the limit.

*New in version 3.6.*

*Changed in version 3.6.2:* The `filename` parameter accepts a [path-like object](#).

*New in version 3.8:* The *strict\_timestamps* keyword-only argument

Instances have the following methods and attributes:

`ZipInfo.is_dir()`

Return `True` if this archive member is a directory.

This uses the entry's name: directories should always end with `/`.

*New in version 3.6.*

`ZipInfo.filename`

Name of the file in the archive.

`ZipInfo.date_time`

The time and date of the last modification to the archive member. This is a tuple of six values:

**~~Index~~**

---

~~Year ( $\geq 1980$ )~~

---

~~Month (one-based)~~

---

~~Day of month (one-based)~~

---

~~Hours (zero-based)~~

---

~~Minutes (zero-based)~~

---

~~Seconds (zero-based)~~

---

**Note**

The ZIP file format does not support timestamps before 1980.

`ZipInfo.compress_type`

Type of compression for the archive member.

`ZipInfo.comment`

Comment for the individual archive member as a **bytes**

object.

### ZipInfo.extra

Expansion field data. The [PKZIP Application Note](https://pkware.cachefly.net/webdocs/casestudies/APPNOTE.TXT) [https://pkware.cachefly.net/webdocs/casestudies/APPNOTE.TXT] contains some comments on the internal structure of the data contained in this **bytes** object.

### ZipInfo.create\_system

System which created ZIP archive.

### ZipInfo.create\_version

PKZIP version which created ZIP archive.

### ZipInfo.extract\_version

PKZIP version needed to extract archive.

### ZipInfo.reserved

Must be zero.

### ZipInfo.flag\_bits

ZIP flag bits.

### ZipInfo.volume

Volume number of file header.

### ZipInfo.internal\_attr

Internal attributes.

### ZipInfo.external\_attr

External file attributes.

### ZipInfo.header\_offset

Byte offset to the file header.

### ZipInfo.CRC

CRC-32 of the uncompressed file.

`ZipInfo.compress_size`

Size of the compressed data.

`ZipInfo.file_size`

Size of the uncompressed file.

## Command-Line Interface

The **zipfile** module provides a simple command-line interface to interact with ZIP archives.

If you want to create a new ZIP archive, specify its name after the **-c** option and then list the filename(s) that should be included:

```
$ python -m zipfile -c monty.zip spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m zipfile -c monty.zip life-of-brian_1979/
```

If you want to extract a ZIP archive into the specified directory, use the **-e** option:

```
$ python -m zipfile -e monty.zip target-dir/
```

For a list of the files in a ZIP archive, use the **-l** option:

```
$ python -m zipfile -l monty.zip
```

## Command-line options

**-l** <zipfile>

**--list** <zipfile>

List files in a zipfile.

**-c** <zipfile> <source1> ... <sourceN>

**--create** <zipfile> <source1> ... <sourceN>

Create zipfile from source files.

`-e <zipfile> <output_dir>`

`--extract <zipfile> <output_dir>`

Extract zipfile into target directory.

`-t <zipfile>`

`--test <zipfile>`

Test whether the zipfile is valid or not.

`--metadata-encoding <encoding>`

Specify encoding of member names for `-l`, `-e` and `-t`.

*New in version 3.11.*

## Decompression pitfalls

The extraction in zipfile module might fail due to some pitfalls listed below.

### From file itself

Decompression may fail due to incorrect password / CRC checksum / ZIP format or unsupported compression method / decryption.

### File System limitations

Exceeding limitations on different file systems can cause decompression failed. Such as allowable characters in the directory entries, length of the file name, length of the pathname, size of a single file, and number of files, etc.

### Resources limitations

The lack of memory or disk volume would lead to decompression failed. For example, decompression bombs (aka [ZIP bomb](https://en.wikipedia.org/wiki/Zip_bomb)) apply to zipfile library that can cause disk volume exhaustion.

## **Interruption**

Interruption during the decompression, such as pressing control-C or killing the decompression process may result in incomplete decompression of the archive.

## **Default behaviors of extraction**

Not knowing the default extraction behaviors can cause unexpected decompression results. For example, when extracting the same archive twice, it overwrites files without asking.

# tarfile — Read and write tar archive files

**Source code:** [Lib/tarfile.py](https://github.com/python/cpython/tree/3.11/Lib/tarfile.py) [https://github.com/python/cpython/tree/3.11/Lib/tarfile.py]

---

The **tarfile** module makes it possible to read and write tar archives, including those using gzip, bz2 and lzma compression. Use the **zipfile** module to read or write .zip files, or the higher-level functions in [shutil](#).

Some facts and figures:

- reads and writes **gzip**, **bz2** and **lzma** compressed archives if the respective modules are available.
- read/write support for the POSIX.1-1988 (ustar) format.
- read/write support for the GNU tar format including *longname* and *longlink* extensions, read-only support for all variants of the *sparse* extension including restoration of sparse files.
- read/write support for the POSIX.1-2001 (pax) format.
- handles directories, regular files, hardlinks, symbolic links, fifos, character devices and block devices and is able to acquire and restore file information like timestamp, access permissions and owner.

*Changed in version 3.3:* Added support for **lzma** compression.

`tarfile.open(name=None, mode='r', fileobj=None, bufsize=10240, **kwargs)`

Return a **TarFile** object for the pathname *name*. For detailed information on **TarFile** objects and the keyword arguments that are allowed, see [TarFile Objects](#).

*mode* has to be a string of the form

'filemode[:compression]', it defaults to 'r'. Here is a full list of mode combinations:

### **~~mode~~**

---

~~Open for reading with transparent compression~~  
(recommended).

---

~~Open for reading exclusively without compression.~~

---

~~Open for reading with gzip compression.~~

---

~~Open for reading with bzip2 compression.~~

---

~~Open for reading with lzma compression.~~

---

~~Create a tarfile exclusively without compression. Raise a~~  
**FileExistsError** exception if it already exists.

---

~~Create a tarfile with gzip compression. Raise a~~  
**FileExistsError** exception if it already exists.

---

~~Create a tarfile with bzip2 compression. Raise a~~  
**FileExistsError** exception if it already exists.

---

~~Create a tarfile with lzma compression. Raise a~~  
**FileExistsError** exception if it already exists.

---

~~Open for appending with no compression. The file is~~  
created if it does not exist.

---

~~Open for uncompressed writing.~~

---

~~Open for gzip compressed writing.~~

---

~~Open for bzip2 compressed writing.~~

---

~~Open for lzma compressed writing.~~

---

Note that 'a:gz', 'a:bz2' or 'a:xz' is not possible. If *mode* is not suitable to open a certain (compressed) file for reading, **ReadError** is raised. Use *mode* 'r' to avoid this. If a compression method is not supported, **CompressionError** is raised.

If *fileobj* is specified, it is used as an alternative to a [file object](#) opened in binary mode for *name*. It is supposed to be at position 0.

For modes 'w:gz', 'r:gz', 'w:bz2', 'r:bz2', 'x:gz', 'x:bz2', **tarfile.open()** accepts the keyword argument *compresslevel* (default 9) to specify the compression level of the file.

For modes 'w:xz' and 'x:xz', **tarfile.open()**

accepts the keyword argument *preset* to specify the compression level of the file.

For special purposes, there is a second format for *mode*:  
'filemode|[compression]'. `tarfile.open()` will return a `TarFile` object that processes its data as a stream of blocks. No random seeking will be done on the file. If given, *fileobj* may be any object that has a `read()` or `write()` method (depending on the *mode*). *bufsize* specifies the blocksize and defaults to `20 * 512` bytes. Use this variant in combination with e.g. `sys.stdin`, a socket `file object` or a tape device. However, such a `TarFile` object is limited in that it does not allow random access, see [Examples](#). The currently possible modes:

### **~~Mode~~**

---

~~Open~~ a *stream* of tar blocks for reading with transparent compression.

---

~~Open~~ a *stream* of uncompressed tar blocks for reading.

---

~~Open~~ a 'gzip compressed *stream* for reading.

---

~~Open~~ a 'bzip2 compressed *stream* for reading.

---

~~Open~~ a 'lzma compressed *stream* for reading.

---

~~Open~~ an uncompressed *stream* for writing.

---

~~Open~~ a 'gzip compressed *stream* for writing.

---

~~Open~~ a 'bzip2 compressed *stream* for writing.

---

~~Open~~ a 'lzma compressed *stream* for writing.

---

*Changed in version 3.5:* The 'x' (exclusive creation) mode was added.

*Changed in version 3.6:* The *name* parameter accepts a [path-like object](#).

`class tarfile.TarFile`

Class for reading and writing tar archives. Do not use this class directly: use `tarfile.open()` instead. See [TarFile Objects](#).

`tarfile.is_tarfile(name)`

Return `True` if *name* is a tar archive file, that the `tarfile`

module can read. *name* may be a `str`, file, or file-like object.

*Changed in version 3.9:* Support for file and file-like objects.

The `tarfile` module defines the following exceptions:

*exception* `tarfile.TarError`

Base class for all `tarfile` exceptions.

*exception* `tarfile.ReadError`

Is raised when a tar archive is opened, that either cannot be handled by the `tarfile` module or is somehow invalid.

*exception* `tarfile.CompressionError`

Is raised when a compression method is not supported or when the data cannot be decoded properly.

*exception* `tarfile.StreamError`

Is raised for the limitations that are typical for stream-like `TarFile` objects.

*exception* `tarfile.ExtractError`

Is raised for *non-fatal* errors when using `TarFile.extract()`, but only if `TarFile.errorlevel == 2`.

*exception* `tarfile.HeaderError`

Is raised by `TarInfo.frombuf()` if the buffer it gets is invalid.

*exception* `tarfile.FilterError`

Base class for members *refused* by filters.

`tarinfo`

Information about the member that the filter refused to extract, as `TarInfo`.

*exception* `tarfile.AbsolutePathError`

Raised to refuse extracting a member with an absolute path.

*exception* `tarfile.OutsideDestinationError`

Raised to refuse extracting a member outside the destination directory.

*exception* `tarfile.SpecialFileError`

Raised to refuse extracting a special file (e.g. a device or pipe).

*exception* `tarfile.AbsoluteLinkError`

Raised to refuse extracting a symbolic link with an absolute path.

*exception* `tarfile.LinkOutsideDestinationError`

Raised to refuse extracting a symbolic link pointing outside the destination directory.

The following constants are available at the module level:

`tarfile.ENCODING`

The default character encoding: `'utf-8'` on Windows, the value returned by `sys.getfilesystemencoding()` otherwise.

Each of the following constants defines a tar archive format that the **tarfile** module is able to create. See section [Supported tar formats](#) for details.

`tarfile.USTAR_FORMAT`

POSIX.1-1988 (ustar) format.

`tarfile.GNU_FORMAT`

GNU tar format.

`tarfile.PAX_FORMAT`

POSIX.1-2001 (pax) format.

`tarfile.DEFAULT_FORMAT`

The default format for creating archives. This is currently [PAX\\_FORMAT](#).

*Changed in version 3.8:* The default format for new archives was changed to [PAX\\_FORMAT](#) from [GNU\\_FORMAT](#).

## TarFile Objects

The [TarFile](#) object provides an interface to a tar archive. A tar archive is a sequence of blocks. An archive member (a stored file) is made up of a header block followed by data blocks. It is possible to store a file in a tar archive several times. Each archive member is represented by a [TarInfo](#) object, see [TarInfo Objects](#) for details.

A [TarFile](#) object can be used as a context manager in a [with](#) statement. It will automatically be closed when the block is completed. Please note that in the event of an exception an archive opened for writing will not be finalized; only the internally used file object will be closed. See the [Examples](#) section for a use case.

*New in version 3.2:* Added support for the context management protocol.

```
class tarfile.TarFile(name=None, mode='r', fileobj=None,
```

*format* = *DEFAULT\_FORMAT*, *tarinfo* = *TarInfo*, *dereference* = *False*,  
*ignore\_zeros* = *False*, *encoding* = *ENCODING*, *errors* = 'surrogateescape',  
*pax\_headers* = *None*, *debug* = 0, *errorlevel* = 1)

All following arguments are optional and can be accessed as instance attributes as well.

*name* is the pathname of the archive. *name* may be a [path-like object](#). It can be omitted if *fileobj* is given. In this case, the file object's **name** attribute is used if it exists.

*mode* is either 'r' to read from an existing archive, 'a' to append data to an existing file, 'w' to create a new file overwriting an existing one, or 'x' to create a new file only if it does not already exist.

If *fileobj* is given, it is used for reading or writing data. If it can be determined, *mode* is overridden by *fileobj*'s mode. *fileobj* will be used from position 0.

### Note

*fileobj* is not closed, when [TarFile](#) is closed.

*format* controls the archive format for writing. It must be one of the constants [USTAR\\_FORMAT](#), [GNU\\_FORMAT](#) or [PAX\\_FORMAT](#) that are defined at module level. When reading, format will be automatically detected, even if different formats are present in a single archive.

The *tarinfo* argument can be used to replace the default [TarInfo](#) class with a different one.

If *dereference* is [False](#), add symbolic and hard links to the archive. If it is [True](#), add the content of the target files to the archive. This has no effect on systems that do not support symbolic links.

If *ignore\_zeros* is [False](#), treat an empty block as the end of the archive. If it is [True](#), skip empty (and invalid) blocks and try to get as many members as possible. This is only useful for

reading concatenated or damaged archives.

*debug* can be set from 0 (no debug messages) up to 3 (all debug messages). The messages are written to `sys.stderr`.

*errorlevel* controls how extraction errors are handled, see **the corresponding attribute**.

The *encoding* and *errors* arguments define the character encoding to be used for reading or writing the archive and how conversion errors are going to be handled. The default settings will work for most users. See section [Unicode issues](#) for in-depth information.

The *pax\_headers* argument is an optional dictionary of strings which will be added as a pax global header if *format* is [PAX\\_FORMAT](#).

*Changed in version 3.2:* Use `'surrogateescape'` as the default for the *errors* argument.

*Changed in version 3.5:* The `'x'` (exclusive creation) mode was added.

*Changed in version 3.6:* The *name* parameter accepts a [path-like object](#).

*classmethod* `TarFile.open(...)`

Alternative constructor. The `tarfile.open()` function is actually a shortcut to this classmethod.

`TarFile.getmember(name)`

Return a [TarInfo](#) object for member *name*. If *name* can not be found in the archive, [KeyError](#) is raised.

### Note

If a member occurs more than once in the archive, its last occurrence is assumed to be the most up-to-date version.

## TarFile.getmembers()

Return the members of the archive as a list of **TarInfo** objects. The list has the same order as the members in the archive.

## TarFile.getnames()

Return the members as a list of their names. It has the same order as the list returned by **getmembers()**.

## TarFile.list(verbose = True, \*, members = None)

Print a table of contents to `sys.stdout`. If *verbose* is **False**, only the names of the members are printed. If it is **True**, output similar to that of `ls -l` is produced. If optional *members* is given, it must be a subset of the list returned by **getmembers()**.

*Changed in version 3.5:* Added the *members* parameter.

## TarFile.next()

Return the next member of the archive as a **TarInfo** object, when **TarFile** is opened for reading. Return **None** if there is no more available.

## TarFile.extractall(path = '.', members = None, \*, numeric\_owner = False, filter = None)

Extract all members from the archive to the current working directory or directory *path*. If optional *members* is given, it must be a subset of the list returned by **getmembers()**. Directory information like owner, modification time and permissions are set after all members have been extracted. This is done to work around two problems: A directory's modification time is reset each time a file is created in it. And, if a directory's permissions do not allow writing, extracting files to it will fail.

If *numeric\_owner* is **True**, the uid and gid numbers from the tarfile are used to set the owner/group for the extracted files.

Otherwise, the named values from the tarfile are used.

The *filter* argument, which was added in Python 3.11.4, specifies how `members` are modified or rejected before extraction. See [Extraction filters](#) for details. It is recommended to set this explicitly depending on which *tar* features you need to support.

### Warning

Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `". . "`.

Set `filter='data'` to prevent the most dangerous security issues, and read the [Extraction filters](#) section for details.

*Changed in version 3.5:* Added the *numeric\_owner* parameter.

*Changed in version 3.6:* The *path* parameter accepts a [path-like object](#).

*Changed in version 3.11.4:* Added the *filter* parameter.

```
TarFile.extract(member, path="", set_attrs=True, *,  
numeric_owner=False, filter=None)
```

Extract a member from the archive to the current working directory, using its full name. Its file information is extracted as accurately as possible. *member* may be a filename or a [TarInfo](#) object. You can specify a different directory using *path*. *path* may be a [path-like object](#). File attributes (owner, mtime, mode) are set unless *set\_attrs* is false.

The *numeric\_owner* and *filter* arguments are the same as for [extractall\(\)](#).

### Note

The `extract()` method does not take care of several extraction issues. In most cases you should consider using the `extractall()` method.

## Warning

See the warning for `extractall()`.

Set `filter='data'` to prevent the most dangerous security issues, and read the [Extraction filters](#) section for details.

*Changed in version 3.2:* Added the `set_attrs` parameter.

*Changed in version 3.5:* Added the `numeric_owner` parameter.

*Changed in version 3.6:* The `path` parameter accepts a [path-like object](#).

*Changed in version 3.11.4:* Added the `filter` parameter.

## `TarFile.extractfile(member)`

Extract a member from the archive as a file object. *member* may be a filename or a [TarInfo](#) object. If *member* is a regular file or a link, an [io.BufferedReader](#) object is returned. For all other existing members, `None` is returned. If *member* does not appear in the archive, [KeyError](#) is raised.

*Changed in version 3.3:* Return an [io.BufferedReader](#) object.

## `TarFile.errorlevel: int`

If *errorlevel* is 0, errors are ignored when using `TarFile.extract()` and `TarFile.extractall()`. Nevertheless, they appear as error messages in the debug output when *debug* is greater than 0. If 1 (the default), all *fatal* errors are raised as [OSError](#) or [FilterError](#) exceptions. If 2, all *non-fatal* errors are raised as [TarError](#) exceptions as well.

Some exceptions, e.g. ones caused by wrong argument types or data corruption, are always raised.

Custom [extraction filters](#) should raise [FilterError](#) for *fatal* errors and [ExtractError](#) for *non-fatal* ones.

Note that when an exception is raised, the archive may be partially extracted. It is the user's responsibility to clean up.

## `TarFile.extraction_filter`

*New in version 3.11.4.*

The [extraction filter](#) used as a default for the *filter* argument of [extract\(\)](#) and [extractall\(\)](#).

The attribute may be `None` or a callable. String names are not allowed for this attribute, unlike the *filter* argument to [extract\(\)](#).

If `extraction_filter` is `None` (the default), calling an extraction method without a *filter* argument will use the [fully\\_trusted](#) filter for compatibility with previous Python versions.

In Python 3.12+, leaving `extraction_filter=None` will emit a `DeprecationWarning`.

In Python 3.14+, leaving `extraction_filter=None` will cause extraction methods to use the [data](#) filter by default.

The attribute may be set on instances or overridden in subclasses. It also is possible to set it on the `TarFile` class itself to set a global default, although, since it affects all uses of *tarfile*, it is best practice to only do so in top-level applications or [site configuration](#). To set a global default this way, a filter function needs to be wrapped in [staticmethod\(\)](#) to prevent injection of a `self` argument.

`TarFile.add(name, arcname=None, recursive=True, *, filter=None)`

Add the file *name* to the archive. *name* may be any type of file

(directory, fifo, symbolic link, etc.). If given, *arcname* specifies an alternative name for the file in the archive. Directories are added recursively by default. This can be avoided by setting *recursive* to **False**. Recursion adds entries in sorted order. If *filter* is given, it should be a function that takes a **TarInfo** object argument and returns the changed **TarInfo** object. If it instead returns **None** the **TarInfo** object will be excluded from the archive. See [Examples](#) for an example.

*Changed in version 3.2:* Added the *filter* parameter.

*Changed in version 3.7:* Recursion adds entries in sorted order.

`TarFile.addfile(tarinfo, fileobj=None)`

Add the **TarInfo** object *tarinfo* to the archive. If *fileobj* is given, it should be a [binary file](#), and `tarinfo.size` bytes are read from it and added to the archive. You can create **TarInfo** objects directly, or by using `gettaringo()`.

`TarFile.gettarinfo(name=None, arcname=None, fileobj=None)`

Create a **TarInfo** object from the result of `os.stat()` or equivalent on an existing file. The file is either named by *name*, or specified as a [file object](#) *fileobj* with a file descriptor. *name* may be a [path-like object](#). If given, *arcname* specifies an alternative name for the file in the archive, otherwise, the name is taken from *fileobj*'s **name** attribute, or the *name* argument. The name should be a text string.

You can modify some of the **TarInfo**'s attributes before you add it using `addfile()`. If the file object is not an ordinary file object positioned at the beginning of the file, attributes such as **size** may need modifying. This is the case for objects such as **GzipFile**. The **name** may also be modified, in which case *arcname* could be a dummy string.

*Changed in version 3.6:* The *name* parameter accepts a [path-like object](#).

`TarFile.close()`

Close the `TarFile`. In write mode, two finishing zero blocks are appended to the archive.

`TarFile.pax_headers`

A dictionary containing key-value pairs of pax global headers.

## TarInfo Objects

A `TarInfo` object represents one member in a `TarFile`. Aside from storing all required attributes of a file (like file type, size, time, permissions, owner etc.), it provides some useful methods to determine its type. It does *not* contain the file's data itself.

`TarInfo` objects are returned by `TarFile`'s methods `getmember()`, `getmembers()` and `gettartinfo()`.

Modifying the objects returned by `getmember()` or `getmembers()` will affect all subsequent operations on the archive. For cases where this is unwanted, you can use `copy.copy()` or call the `replace()` method to create a modified copy in one step.

Several attributes can be set to `None` to indicate that a piece of metadata is unused or unknown. Different `TarInfo` methods handle `None` differently:

- The `extract()` or `extractall()` methods will ignore the corresponding metadata, leaving it set to a default.
- `addfile()` will fail.
- `list()` will print a placeholder string.

*Changed in version 3.11.4:* Added `replace()` and handling of `None`.

```
class tarfile.TarInfo(name = "")
```

Create a `TarInfo` object.

```
classmethod TarInfo.frombuf(buf, encoding, errors)
```

Create and return a `TarInfo` object from string buffer `buf`.

Raises `HeaderError` if the buffer is invalid.

*classmethod* `TarInfo.fromtarfile(tarfile)`

Read the next member from the `TarFile` object *tarfile* and return it as a `TarInfo` object.

`TarInfo.tobuf(format=DEFAULT_FORMAT, encoding=ENCODING, errors='surrogateescape')`

Create a string buffer from a `TarInfo` object. For information on the arguments see the constructor of the `TarFile` class.

*Changed in version 3.2:* Use `'surrogateescape'` as the default for the *errors* argument.

A `TarInfo` object has the following public data attributes:

`TarInfo.name`: *str*

Name of the archive member.

`TarInfo.size`: *int*

Size in bytes.

`TarInfo.mtime`: *int* | *float*

Time of last modification in seconds since the *epoch*, as in `os.stat_result.st_mtime`.

*Changed in version 3.11.4:* Can be set to `None` for `extract()` and `extractall()`, causing extraction to skip applying this attribute.

`TarInfo.mode`: *int*

Permission bits, as for `os.chmod()`.

*Changed in version 3.11.4:* Can be set to `None` for `extract()` and `extractall()`, causing extraction to skip applying this attribute.

TarInfo.type

File type. *type* is usually one of these constants: **REGTYPE**, **AREGTYPE**, **LNKTYPE**, **SYMTYPE**, **DIRTYPE**, **FIFOTYPE**, **CONTTYPE**, **CHRTYPE**, **BLKTYPE**, **GNUTYPE\_SPARSE**. To determine the type of a **TarInfo** object more conveniently, use the `is*()` methods below.

TarInfo.linkname: *str*

Name of the target file name, which is only present in **TarInfo** objects of type **LNKTYPE** and **SYMTYPE**.

TarInfo.uid: *int*

User ID of the user who originally stored this member.

*Changed in version 3.11.4:* Can be set to `None` for **extract()** and **extractall()**, causing extraction to skip applying this attribute.

TarInfo.gid: *int*

Group ID of the user who originally stored this member.

*Changed in version 3.11.4:* Can be set to `None` for **extract()** and **extractall()**, causing extraction to skip applying this attribute.

TarInfo.uname: *str*

User name.

*Changed in version 3.11.4:* Can be set to `None` for **extract()** and **extractall()**, causing extraction to skip applying this attribute.

TarInfo.gname: *str*

Group name.

*Changed in version 3.11.4:* Can be set to `None` for **extract()** and **extractall()**, causing extraction to skip applying this attribute.

`TarInfo.pax_headers`: *dict*

A dictionary containing key-value pairs of an associated pax extended header.

`TarInfo.replace(name=..., mtime=..., mode=..., linkname=..., uid=..., gid=..., uname=..., gname=..., deep=True)`

*New in version 3.11.4.*

Return a *new* copy of the **TarInfo** object with the given attributes changed. For example, to return a `TarInfo` with the group name set to `'staff'`, use:

```
new_tarinfo = old_tarinfo.replace(gname='staff')
```

By default, a deep copy is made. If *deep* is false, the copy is shallow, i.e. `pax_headers` and any custom attributes are shared with the original `TarInfo` object.

A **TarInfo** object also provides some convenient query methods:

`TarInfo.isfile()`

Return **True** if the **Tarinfo** object is a regular file.

`TarInfo.isreg()`

Same as `isfile()`.

`TarInfo.isdir()`

Return **True** if it is a directory.

`TarInfo.issym()`

Return **True** if it is a symbolic link.

`TarInfo.islnk()`

Return **True** if it is a hard link.

`TarInfo.ischr()`

Return **True** if it is a character device.

`TarInfo.isblk()`

Return **True** if it is a block device.

`TarInfo.isfifo()`

Return **True** if it is a FIFO.

`TarInfo.isdev()`

Return **True** if it is one of character device, block device or FIFO.

## Extraction filters

*New in version 3.11.4.*

The *tar* format is designed to capture all details of a UNIX-like filesystem, which makes it very powerful. Unfortunately, the features make it easy to create tar files that have unintended – and possibly malicious – effects when extracted. For example, extracting a tar file can overwrite arbitrary files in various ways (e.g. by using absolute paths, `..` path components, or symlinks that affect later members).

In most cases, the full functionality is not needed. Therefore, *tarfile* supports extraction filters: a mechanism to limit functionality, and thus mitigate some of the security issues.

### See also

**PEP 706** [<https://peps.python.org/pep-0706/>]

Contains further motivation and rationale behind the design.

The *filter* argument to `TarFile.extract()` or `extractall()` can be:

- the string `'fully_trusted'`: Honor all metadata as

specified in the archive. Should be used if the user trusts the archive completely, or implements their own complex verification.

- the string `'tar'`: Honor most *tar*-specific features (i.e. features of UNIX-like filesystems), but block features that are very likely to be surprising or malicious. See `tar_filter()` for details.
- the string `'data'`: Ignore or block most features specific to UNIX-like filesystems. Intended for extracting cross-platform data archives. See `data_filter()` for details.
- None (default): Use `TarFile.extraction_filter`.

If that is also None (the default), the `'fully_trusted'` filter will be used (for compatibility with earlier versions of Python).

In Python 3.12, the default will emit a `DeprecationWarning`.

In Python 3.14, the `'data'` filter will become the default instead. It's possible to switch earlier; see `TarFile.extraction_filter`.

- A callable which will be called for each extracted member with a `TarInfo` describing the member and the destination path to where the archive is extracted (i.e. the same path is used for all members):

```
filter(member: TarInfo, path: str, /) -> TarInfo | None
```

The callable is called just before each member is extracted, so it can take the current state of the disk into account. It can:

- return a `TarInfo` object which will be used instead of the metadata in the archive, or
- return `None`, in which case the member will be skipped, or
- raise an exception to abort the operation or skip the member, depending on `errorlevel`. Note that when

extraction is aborted, `extractall()` may leave the archive partially extracted. It does not attempt to clean up.

## Default named filters

The pre-defined, named filters are available as functions, so they can be reused in custom filters:

`tarfile.fully_trusted_filter(member, path)`

Return *member* unchanged.

This implements the 'fully\_trusted' filter.

`tarfile.tar_filter(member, path)`

Implements the 'tar' filter.

- Strip leading slashes (/ and `os.sep`) from filenames.
- **Refuse** to extract files with absolute paths (in case the name is absolute even after stripping slashes, e.g. `C:/foo` on Windows). This raises **AbsolutePathError**.
- **Refuse** to extract files whose absolute path (after following symlinks) would end up outside the destination. This raises **OutsideDestinationError**.
- Clear high mode bits (setuid, setgid, sticky) and group/other write bits (**S\_IWOTH**).

Return the modified `TarInfo` member.

`tarfile.data_filter(member, path)`

Implements the 'data' filter. In addition to what `tar_filter` does:

- **Refuse** to extract links (hard or soft) that link to absolute paths, or ones that link outside the destination.

This raises **AbsoluteLinkError** or **LinkOutsideDestinationError**.

Note that such files are refused even on platforms that do not support symbolic links.

- **Refuse** to extract device files (including pipes). This raises **SpecialFileError**.
- For regular files, including hard links:
  - Set the owner read and write permissions (**S\_IWUSR**).
  - Remove the group & other executable permission (**S\_IXOTH**) if the owner doesn't have it (**S\_IXUSR**).
- For other files (directories), set `mode` to `None`, so that extraction methods skip applying permission bits.
- Set user and group info (`uid`, `gid`, `uname`, `gname`) to `None`, so that extraction methods skip setting it.

Return the modified `TarInfo` member.

## Filter errors

When a filter refuses to extract a file, it will raise an appropriate exception, a subclass of **FilterError**. This will abort the extraction if **TarFile.errorlevel** is 1 or more. With `errorlevel=0` the error will be logged and the member will be skipped, but extraction will continue.

## Hints for further verification

Even with `filter='data'`, *tarfile* is not suited for extracting untrusted files without prior inspection. Among other issues, the pre-defined filters do not prevent denial-of-service attacks. Users should do additional checks.

Here is an incomplete list of things to consider:

- Extract to a **new temporary directory** to prevent e.g. exploiting pre-existing links, and to make it easier to clean up

after a failed extraction.

- When working with untrusted data, use external (e.g. OS-level) limits on disk, memory and CPU usage.
- Check filenames against an allow-list of characters (to filter out control characters, confusables, foreign path separators, etc.).
- Check that filenames have expected extensions (discouraging files that execute when you “click on them”, or extension-less files like Windows special device names).
- Limit the number of extracted files, total size of extracted data, filename length (including symlink length), and size of individual files.
- Check for files that would be shadowed on case-insensitive filesystems.

Also note that:

- Tar files may contain multiple versions of the same file. Later ones are expected to overwrite any earlier ones. This feature is crucial to allow updating tape archives, but can be abused maliciously.
- *tarfile* does not protect against issues with “live” data, e.g. an attacker tinkering with the destination (or source) directory while extraction (or archiving) is in progress.

## Supporting older Python versions

Extraction filters were added to Python 3.12, and are backported to older versions as security updates. To check whether the feature is available, use e.g. `hasattr(tarfile, 'data_filter')` rather than checking the Python version.

The following examples show how to support Python versions with and without the feature. Note that setting `extraction_filter` will affect any subsequent operations.

- Fully trusted archive:

```
my_tarfile.extraction_filter = (lambda member, path:  
my_tarfile.extractall())
```

- Use the 'data' filter if available, but revert to Python 3.11 behavior ('fully\_trusted') if this feature is not available:

```
my_tarfile.extraction_filter = getattr(tarfile, 'data_filter',
                                       (lambda memb
```

- Use the 'data' filter; *fail* if it is not available:

```
my_tarfile.extractall(filter=tarfile.data_filter)
```

or:

```
my_tarfile.extraction_filter = tarfile.data_filter
my_tarfile.extractall()
```

- Use the 'data' filter; *warn* if it is not available:

```
if hasattr(tarfile, 'data_filter'):
    my_tarfile.extractall(filter='data')
else:
    # remove this when no longer needed
    warn_the_user('Extracting may be unsafe; consid
    my_tarfile.extractall()
```

## Stateful extraction filter example

While *tarfile*'s extraction methods take a simple *filter* callable, custom filters may be more complex objects with an internal state. It may be useful to write these as context managers, to be used like this:

```
with StatefulFilter() as filter_func:
    tar.extractall(path, filter=filter_func)
```

Such a filter can be written as, for example:

```
class StatefulFilter:
    def __init__(self):
        self.file_count = 0
```

```
def __enter__(self):
    return self

def __call__(self, member, path):
    self.file_count += 1
    return member

def __exit__(self, *exc_info):
    print(f'{self.file_count} files extracted')
```

## Command-Line Interface

*New in version 3.4.*

The **tarfile** module provides a simple command-line interface to interact with tar archives.

If you want to create a new tar archive, specify its name after the **-c** option and then list the filename(s) that should be included:

```
$ python -m tarfile -c monty.tar spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m tarfile -c monty.tar life-of-brian_1979/
```

If you want to extract a tar archive into the current directory, use the **-e** option:

```
$ python -m tarfile -e monty.tar
```

You can also extract a tar archive into a different directory by passing the directory's name:

```
$ python -m tarfile -e monty.tar other-dir/
```

For a list of the files in a tar archive, use the **-l** option:

```
$ python -m tarfile -l monty.tar
```

## Command-line options

`-l <tarfile>`

`--list <tarfile>`

List files in a tarfile.

`-c <tarfile> <source1> ... <sourceN>`

`--create <tarfile> <source1> ... <sourceN>`

Create tarfile from source files.

`-e <tarfile> [<output_dir>]`

`--extract <tarfile> [<output_dir>]`

Extract tarfile into the current directory if *output\_dir* is not specified.

`-t <tarfile>`

`--test <tarfile>`

Test whether the tarfile is valid or not.

`-v, --verbose`

Verbose output.

`--filter <filtername>`

Specifies the *filter* for `--extract`. See [Extraction filters](#) for details. Only string names are accepted (that is, `fully_trusted`, `tar`, and `data`).

*New in version 3.11.4.*

## Examples

How to extract an entire tar archive to the current working directory:

```
import tarfile
tar = tarfile.open("sample.tar.gz")
tar.extractall()
```

```
tar.close()
```

How to extract a subset of a tar archive with

`TarFile.extractall()` using a generator function instead of a list:

```
import os
import tarfile

def py_files(members):
    for tarinfo in members:
        if os.path.splitext(tarinfo.name)[1] == ".py":
            yield tarinfo

tar = tarfile.open("sample.tar.gz")
tar.extractall(members=py_files(tar))
tar.close()
```

How to create an uncompressed tar archive from a list of filenames:

```
import tarfile
tar = tarfile.open("sample.tar", "w")
for name in ["foo", "bar", "quux"]:
    tar.add(name)
tar.close()
```

The same example using the `with` statement:

```
import tarfile
with tarfile.open("sample.tar", "w") as tar:
    for name in ["foo", "bar", "quux"]:
        tar.add(name)
```

How to read a gzip compressed tar archive and display some member information:

```
import tarfile
tar = tarfile.open("sample.tar.gz", "r:gz")
for tarinfo in tar:
    print(tarinfo.name, "is", tarinfo.size, "bytes in si
```

```
if tarinfo.isreg():
    print("a regular file.")
elif tarinfo.isdir():
    print("a directory.")
else:
    print("something else.")
tar.close()
```

How to create an archive and reset the user information using the *filter* parameter in `TarFile.add()`:

```
import tarfile
def reset(tarinfo):
    tarinfo.uid = tarinfo.gid = 0
    tarinfo.uname = tarinfo.gname = "root"
    return tarinfo
tar = tarfile.open("sample.tar.gz", "w:gz")
tar.add("foo", filter=reset)
tar.close()
```

## Supported tar formats

There are three tar formats that can be created with the `tarfile` module:

- The POSIX.1-1988 ustar format (`USTAR_FORMAT`). It supports filenames up to a length of at best 256 characters and linknames up to 100 characters. The maximum file size is 8 GiB. This is an old and limited but widely supported format.
- The GNU tar format (`GNU_FORMAT`). It supports long filenames and linknames, files bigger than 8 GiB and sparse files. It is the de facto standard on GNU/Linux systems. `tarfile` fully supports the GNU tar extensions for long names, sparse file support is read-only.
- The POSIX.1-2001 pax format (`PAX_FORMAT`). It is the most flexible format with virtually no limits. It supports long filenames and linknames, large files and stores pathnames in a portable way. Modern tar implementations, including GNU

tar, bsdtar/libarchive and star, fully support extended *pax* features; some old or unmaintained libraries may not, but should treat *pax* archives as if they were in the universally supported *ustar* format. It is the current default format for new archives.

It extends the existing *ustar* format with extra headers for information that cannot be stored otherwise. There are two flavours of *pax* headers: Extended headers only affect the subsequent file header, global headers are valid for the complete archive and affect all following files. All the data in a *pax* header is encoded in *UTF-8* for portability reasons.

There are some more variants of the tar format which can be read, but not created:

- The ancient V7 format. This is the first tar format from Unix Seventh Edition, storing only regular files and directories. Names must not be longer than 100 characters, there is no user/group name information. Some archives have miscalculated header checksums in case of fields with non-ASCII characters.
- The SunOS tar extended format. This format is a variant of the POSIX.1-2001 *pax* format, but is not compatible.

## Unicode issues

The tar format was originally conceived to make backups on tape drives with the main focus on preserving file system information. Nowadays tar archives are commonly used for file distribution and exchanging archives over networks. One problem of the original format (which is the basis of all other formats) is that there is no concept of supporting different character encodings. For example, an ordinary tar archive created on a *UTF-8* system cannot be read correctly on a *Latin-1* system if it contains non-ASCII characters. Textual metadata (like filenames, linknames, user/group names) will appear damaged. Unfortunately, there is no way to autodetect the encoding of an archive. The *pax* format was designed to solve this problem. It stores non-ASCII metadata using the universal character encoding *UTF-8*.

The details of character conversion in **tarfile** are controlled by the *encoding* and *errors* keyword arguments of the **TarFile** class.

*encoding* defines the character encoding to use for the metadata in the archive. The default value is **sys.getfilesystemencoding()** or `'ascii'` as a fallback. Depending on whether the archive is read or written, the metadata must be either decoded or encoded. If *encoding* is not set appropriately, this conversion may fail.

The *errors* argument defines how characters are treated that cannot be converted. Possible values are listed in section **Error Handlers**. The default scheme is `'surrogateescape'` which Python also uses for its file system calls, see **File Names, Command Line Arguments, and Environment Variables**.

For **PAX\_FORMAT** archives (the default), *encoding* is generally not needed because all the metadata is stored using *UTF-8*. *encoding* is only used in the rare cases when binary pax headers are decoded or when strings with surrogate characters are stored.

# File Formats

The modules described in this chapter parse various miscellaneous file formats that aren't markup languages and are not related to e-mail.

- **csv** — CSV File Reading and Writing
  - Module Contents
  - Dialects and Formatting Parameters
  - Reader Objects
  - Writer Objects
  - Examples
- **configparser** — Configuration file parser
  - Quick Start
  - Supported Datatypes
  - Fallback Values
  - Supported INI File Structure
  - Interpolation of values
  - Mapping Protocol Access
  - Customizing Parser Behaviour
  - Legacy API Examples
  - ConfigParser Objects
  - RawConfigParser Objects
  - Exceptions
- **tomllib** — Parse TOML files
  - Examples
  - Conversion Table
- **netrc** — netrc file processing
  - netrc Objects

- **plistlib** — Generate and parse Apple **.plist** files
  - Examples

# csv — CSV File Reading and Writing

**Source code:** [Lib/csv.py](https://github.com/python/cpython/tree/3.11/Lib/csv.py) [https://github.com/python/cpython/tree/3.11/Lib/csv.py]

---

The so-called CSV (Comma Separated Values) format is the most common import and export format for spreadsheets and databases. CSV format was used for many years prior to attempts to describe the format in a standardized way in [RFC 4180](https://datatracker.ietf.org/doc/html/rfc4180.html) [https://datatracker.ietf.org/doc/html/rfc4180.html]. The lack of a well-defined standard means that subtle differences often exist in the data produced and consumed by different applications. These differences can make it annoying to process CSV files from multiple sources. Still, while the delimiters and quoting characters vary, the overall format is similar enough that it is possible to write a single module which can efficiently manipulate such data, hiding the details of reading and writing the data from the programmer.

The `csv` module implements classes to read and write tabular data in CSV format. It allows programmers to say, “write this data in the format preferred by Excel,” or “read data from this file which was generated by Excel,” without knowing the precise details of the CSV format used by Excel. Programmers can also describe the CSV formats understood by other applications or define their own special-purpose CSV formats.

The `csv` module’s `reader` and `writer` objects read and write sequences. Programmers can also read and write data in dictionary form using the `DictReader` and `DictWriter` classes.

**See also**

**PEP 305** [https://peps.python.org/pep-0305/] - CSV File API

The Python Enhancement Proposal which proposed this addition to Python.

## Module Contents

The **csv** module defines the following functions:

`csv.reader(csvfile, dialect='excel', **fmtparams)`

Return a reader object which will iterate over lines in the given *csvfile*. *csvfile* can be any object which supports the [iterator](#) protocol and returns a string each time its `__next__()` method is called — [file objects](#) and list objects are both suitable. If *csvfile* is a file object, it should be opened with `newline=''`. **1** An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the [Dialect](#) class or one of the strings returned by the [list\\_dialects\(\)](#) function. The other optional *fmtparams* keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section [Dialects and Formatting Parameters](#).

Each row read from the csv file is returned as a list of strings. No automatic data type conversion is performed unless the `QUOTE_NONNUMERIC` format option is specified (in which case unquoted fields are transformed into floats).

A short usage example:

```
>>> import csv
>>> with open('eggs.csv', newline='') as csvfile:
...     spamreader = csv.reader(csvfile, delimiter=
...     for row in spamreader:
...         print(', '.join(row))
Spam, Spam, Spam, Spam, Spam, Baked Beans
Spam, Lovely Spam, Wonderful Spam
```

`csv.writer(csvfile, dialect='excel', **fmtparams)`

Return a writer object responsible for converting the user's data into delimited strings on the given file-like object. *csvfile* can be any object with a **write()** method. If *csvfile* is a file object, it should be opened with `newline=''` <sup>1</sup>. An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the **Dialect** class or one of the strings returned by the **list\_dialects()** function. The other optional *fmtparams* keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about dialects and formatting parameters, see the [Dialects and Formatting Parameters](#) section. To make it as easy as possible to interface with modules which implement the DB API, the value **None** is written as the empty string. While this isn't a reversible transformation, it makes it easier to dump SQL NULL data values to CSV files without preprocessing the data returned from a `cursor.fetch*` call. All other non-string data are stringified with **str()** before being written.

A short usage example:

```
import csv
with open('eggs.csv', 'w', newline='') as csvfile:
    spamwriter = csv.writer(csvfile, delimiter=' ',
                            quotechar='|', quoting=
    spamwriter.writerow(['Spam'] * 5 + ['Baked Bean'])
    spamwriter.writerow(['Spam', 'Lovely Spam', 'Wo'])
```

`csv.register_dialect(name[, dialect[, **fmtparams]])`

Associate *dialect* with *name*. *name* must be a string. The dialect can be specified either by passing a sub-class of **Dialect**, or by *fmtparams* keyword arguments, or both, with keyword arguments overriding parameters of the dialect. For full details about dialects and formatting parameters, see section [Dialects and Formatting Parameters](#).

`csv.unregister_dialect(name)`

Delete the dialect associated with *name* from the dialect registry. An **Error** is raised if *name* is not a registered dialect name.

`csv.get_dialect(name)`

Return the dialect associated with *name*. An **Error** is raised if *name* is not a registered dialect name. This function returns an immutable **Dialect**.

`csv.list_dialects()`

Return the names of all registered dialects.

`csv.field_size_limit([new_limit])`

Returns the current maximum field size allowed by the parser. If *new\_limit* is given, this becomes the new limit.

The **csv** module defines the following classes:

```
class csv.DictReader(f, fieldnames=None, restkey=None,
restval=None, dialect='excel', *args, **kwargs)
```

Create an object that operates like a regular reader but maps the information in each row to a **dict** whose keys are given by the optional *fieldnames* parameter.

The *fieldnames* parameter is a **sequence**. If *fieldnames* is omitted, the values in the first row of file *f* will be used as the fieldnames. Regardless of how the fieldnames are determined, the dictionary preserves their original ordering.

If a row has more fields than fieldnames, the remaining data is put in a list and stored with the fieldname specified by *restkey* (which defaults to `None`). If a non-blank row has fewer fields than fieldnames, the missing values are filled-in with the value of *restval* (which defaults to `None`).

All other optional or keyword arguments are passed to the underlying **reader** instance.

*Changed in version 3.6:* Returned rows are now of type **OrderedDict**.

*Changed in version 3.8:* Returned rows are now of type **dict**.

A short usage example:

```
>>> import csv
>>> with open('names.csv', newline='') as csvfile:
...     reader = csv.DictReader(csvfile)
...     for row in reader:
...         print(row['first_name'], row['last_name'])
...
Eric Idle
John Cleese

>>> print(row)
{'first_name': 'John', 'last_name': 'Cleese'}
```

*class* csv.DictWriter(*f*, *fieldnames*, *restval*="", *extrasaction*='raise',  
*dialect*='excel', \**args*, \*\**kwds*)

Create an object which operates like a regular writer but maps dictionaries onto output rows. The *fieldnames* parameter is a **sequence** of keys that identify the order in which values in the dictionary passed to the **writerow()** method are written to file *f*. The optional *restval* parameter specifies the value to be written if the dictionary is missing a key in *fieldnames*. If the dictionary passed to the **writerow()** method contains a key not found in *fieldnames*, the optional *extrasaction* parameter indicates what action to take. If it is set to 'raise', the default value, a **ValueError** is raised. If it is set to 'ignore', extra values in the dictionary are ignored. Any other optional or keyword arguments are passed to the underlying **writer** instance.

Note that unlike the **DictReader** class, the *fieldnames* parameter of the **DictWriter** class is not optional.

A short usage example:

```
import csv

with open('names.csv', 'w', newline='') as csvfile:
    fieldnames = ['first_name', 'last_name']
    writer = csv.DictWriter(csvfile, fieldnames=fieldnames)

    writer.writeheader()
    writer.writerow({'first_name': 'Baked', 'last_name': 'Smith'})
    writer.writerow({'first_name': 'Lovely', 'last_name': 'Packard'})
    writer.writerow({'first_name': 'Wonderful', 'last_name': 'Butterfield'})
```

### *class csv.Dialect*

The **Dialect** class is a container class whose attributes contain information for how to handle doublequotes, whitespace, delimiters, etc. Due to the lack of a strict CSV specification, different applications produce subtly different CSV data. **Dialect** instances define how **reader** and **writer** instances behave.

All available **Dialect** names are returned by **list\_dialects()**, and they can be registered with specific **reader** and **writer** classes through their initializer (**\_\_init\_\_**) functions like this:

```
import csv

with open('students.csv', 'w', newline='') as csvfile:
    writer = csv.writer(csvfile, dialect='unix')
    # ^^^^^^^^^^^^^^^^^^
```

### *class csv.excel*

The **excel** class defines the usual properties of an Excel-generated CSV file. It is registered with the dialect name 'excel'.

### *class csv.excel\_tab*

The **excel\_tab** class defines the usual properties of an Excel-generated TAB-delimited file. It is registered with the dialect name 'excel-tab'.

*class* csv.unix\_dialect

The **unix\_dialect** class defines the usual properties of a CSV file generated on UNIX systems, i.e. using `'\n'` as line terminator and quoting all fields. It is registered with the dialect name `'unix'`.

*New in version 3.2.*

*class* csv.Sniffer

The **Sniffer** class is used to deduce the format of a CSV file.

The **Sniffer** class provides two methods:

**sniff**(*sample*, *delimiters* = None)

Analyze the given *sample* and return a **Dialect** subclass reflecting the parameters found. If the optional *delimiters* parameter is given, it is interpreted as a string containing possible valid delimiter characters.

**has\_header**(*sample*)

Analyze the sample text (presumed to be in CSV format) and return **True** if the first row appears to be a series of column headers. Inspecting each column, one of two key criteria will be considered to estimate if the sample contains a header:

- the second through n-th rows contain numeric values
- the second through n-th rows contain strings where at least one value's length differs from that of the putative header of that column.

Twenty rows after the first row are sampled; if more than half of columns + rows meet the criteria, **True** is returned.

## Note

This method is a rough heuristic and may produce both false positives and negatives.

An example for **Sniffer** use:

```
with open('example.csv', newline='') as csvfile:
    dialect = csv.Sniffer().sniff(csvfile.read(1024))
    csvfile.seek(0)
    reader = csv.reader(csvfile, dialect)
    # ... process CSV file contents here ...
```

The **csv** module defines the following constants:

**csv.QUOTE\_ALL**

Instructs **writer** objects to quote all fields.

**csv.QUOTE\_MINIMAL**

Instructs **writer** objects to only quote those fields which contain special characters such as *delimiter*, *quotechar* or any of the characters in *lineterminator*.

**csv.QUOTE\_NONNUMERIC**

Instructs **writer** objects to quote all non-numeric fields.

Instructs the reader to convert all non-quoted fields to type *float*.

**csv.QUOTE\_NONE**

Instructs **writer** objects to never quote fields. When the current *delimiter* occurs in output data it is preceded by the current *escapechar* character. If *escapechar* is not set, the writer will raise **Error** if any characters that require escaping are encountered.

Instructs **reader** to perform no special processing of quote characters.

The **csv** module defines the following exception:

*exception* csv.Error

Raised by any of the functions when an error is detected.

## Dialects and Formatting Parameters

To make it easier to specify the format of input and output records, specific formatting parameters are grouped together into dialects. A dialect is a subclass of the **Dialect** class having a set of specific methods and a single **validate()** method. When creating **reader** or **writer** objects, the programmer can specify a string or a subclass of the **Dialect** class as the dialect parameter. In addition to, or instead of, the *dialect* parameter, the programmer can also specify individual formatting parameters, which have the same names as the attributes defined below for the **Dialect** class.

Dialects support the following attributes:

Dialect.delimiter

A one-character string used to separate fields. It defaults to **' , ' .**

Dialect.doublequote

Controls how instances of *quotechar* appearing inside a field should themselves be quoted. When **True**, the character is doubled. When **False**, the *escapechar* is used as a prefix to the *quotechar*. It defaults to **True**.

On output, if *doublequote* is **False** and no *escapechar* is set, **Error** is raised if a *quotechar* is found in a field.

Dialect.escapechar

A one-character string used by the writer to escape the *delimiter* if *quoting* is set to **QUOTE\_NONE** and the *quotechar* if *doublequote* is **False**. On reading, the *escapechar* removes any special meaning from the following character. It defaults to **None**, which disables escaping.

*Changed in version 3.11:* An empty *escapechar* is not allowed.

#### Dialect.lineterminator

The string used to terminate lines produced by the **writer**. It defaults to `'\r\n'`.

#### Note

The **reader** is hard-coded to recognise either `'\r'` or `'\n'` as end-of-line, and ignores *lineterminator*. This behavior may change in the future.

#### Dialect.quotechar

A one-character string used to quote fields containing special characters, such as the *delimiter* or *quotechar*, or which contain new-line characters. It defaults to `'\"'`.

*Changed in version 3.11:* An empty *quotechar* is not allowed.

#### Dialect.quoting

Controls when quotes should be generated by the writer and recognised by the reader. It can take on any of the **QUOTE\_\*** constants (see section [Module Contents](#)) and defaults to **QUOTE\_MINIMAL**.

#### Dialect.skipinitialspace

When **True**, spaces immediately following the *delimiter* are ignored. The default is **False**.

#### Dialect.strict

When **True**, raise exception **Error** on bad CSV input. The default is **False**.

## Reader Objects

Reader objects (**DictReader** instances and objects returned by the **reader()** function) have the following public methods:

`csvreader._next_()`

Return the next row of the reader's iterable object as a list (if the object was returned from `reader()`) or a dict (if it is a `DictReader` instance), parsed according to the current `Dialect`. Usually you should call this as `next(reader)`.

Reader objects have the following public attributes:

`csvreader.dialect`

A read-only description of the dialect in use by the parser.

`csvreader.line_num`

The number of lines read from the source iterator. This is not the same as the number of records returned, as records can span multiple lines.

`DictReader` objects have the following public attribute:

`DictReader.fieldnames`

If not passed as a parameter when creating the object, this attribute is initialized upon first access or when the first record is read from the file.

## Writer Objects

**Writer** objects (`DictWriter` instances and objects returned by the `writer()` function) have the following public methods. A *row* must be an iterable of strings or numbers for **Writer** objects and a dictionary mapping fieldnames to strings or numbers (by passing them through `str()` first) for `DictWriter` objects. Note that complex numbers are written out surrounded by parens. This may cause some problems for other programs which read CSV files (assuming they support complex numbers at all).

`csvwriter.writerow(row)`

Write the *row* parameter to the writer's file object, formatted according to the current `Dialect`. Return the return value of the call to the *write* method of the underlying file object.

*Changed in version 3.5:* Added support of arbitrary iterables.

`csvwriter.writerows(rows)`

Write all elements in *rows* (an iterable of *row* objects as described above) to the writer's file object, formatted according to the current dialect.

Writer objects have the following public attribute:

`csvwriter.dialect`

A read-only description of the dialect in use by the writer.

DictWriter objects have the following public method:

`DictWriter.writeheader()`

Write a row with the field names (as specified in the constructor) to the writer's file object, formatted according to the current dialect. Return the return value of the `csvwriter.writerow()` call used internally.

*New in version 3.2.*

*Changed in version 3.8:* `writeheader()` now also returns the value returned by the `csvwriter.writerow()` method it uses internally.

## Examples

The simplest example of reading a CSV file:

```
import csv
with open('some.csv', newline='') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

Reading a file with an alternate format:

```
import csv
```

```
with open('passwd', newline='') as f:
    reader = csv.reader(f, delimiter=':', quoting=csv.QUOTE_MINIMAL)
    for row in reader:
        print(row)
```

The corresponding simplest possible writing example is:

```
import csv
with open('some.csv', 'w', newline='') as f:
    writer = csv.writer(f)
    writer.writerows(someiterable)
```

Since `open()` is used to open a CSV file for reading, the file will by default be decoded into unicode using the system default encoding (see `locale.getencoding()`). To decode a file using a different encoding, use the `encoding` argument of `open`:

```
import csv
with open('some.csv', newline='', encoding='utf-8') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

The same applies to writing in something other than the system default encoding: specify the `encoding` argument when opening the output file.

Registering a new dialect:

```
import csv
csv.register_dialect('unixpwd', delimiter=':', quoting=csv.QUOTE_MINIMAL)
with open('passwd', newline='') as f:
    reader = csv.reader(f, 'unixpwd')
```

A slightly more advanced use of the reader — catching and reporting errors:

```
import csv, sys
filename = 'some.csv'
with open(filename, newline='') as f:
    reader = csv.reader(f)
```

```
try:
    for row in reader:
        print(row)
except csv.Error as e:
    sys.exit('file {}, line {}: {}'.format(filename,
```

And while the module doesn't directly support parsing strings, it can easily be done:

```
import csv
for row in csv.reader(['one,two,three']):
    print(row)
```

## Footnotes

1([1](#),[2](#))

If `newline=''` is not specified, newlines embedded inside quoted fields will not be interpreted correctly, and on platforms that use `\r\n` line endings on write an extra `\r` will be added. It should always be safe to specify `newline=''`, since the `csv` module does its own ([universal](#)) newline handling.

# configparser — Configuration file parser

**Source code:** [Lib/configparser.py](https://github.com/python/cpython/tree/3.11/Lib/configparser.py) [https://github.com/python/cpython/tree/3.11/Lib/configparser.py]

---

This module provides the `ConfigParser` class which implements a basic configuration language which provides a structure similar to what's found in Microsoft Windows INI files. You can use this to write Python programs which can be customized by end users easily.

## Note

This library does *not* interpret or write the value-type prefixes used in the Windows Registry extended version of INI syntax.

## See also

### Module `tomllib`

TOML is a well-specified format for application configuration files. It is specifically designed to be an improved version of INI.

### Module `shlex`

Support for creating Unix shell-like mini-languages which can also be used for application configuration files.

### Module `json`

The `json` module implements a subset of JavaScript syntax which is sometimes used for configuration, but does not support comments.

# Quick Start

Let's take a very basic configuration file that looks like this:

```
[DEFAULT]
ServerAliveInterval = 45
Compression = yes
CompressionLevel = 9
ForwardX11 = yes

[forge.example]
User = hg

[topsecret.server.example]
Port = 50022
ForwardX11 = no
```

The structure of INI files is described [in the following section](#).

Essentially, the file consists of sections, each of which contains keys with values. [configparser](#) classes can read and write such files.

Let's start by creating the above configuration file programmatically.

```
>>> import configparser
>>> config = configparser.ConfigParser()
>>> config['DEFAULT'] = {'ServerAliveInterval': '45',
...                     'Compression': 'yes',
...                     'CompressionLevel': '9'}
>>> config['forge.example'] = {}
>>> config['forge.example']['User'] = 'hg'
>>> config['topsecret.server.example'] = {}
>>> topsecret = config['topsecret.server.example']
>>> topsecret['Port'] = '50022'      # mutates the parser
>>> topsecret['ForwardX11'] = 'no'   # same here
>>> config['DEFAULT']['ForwardX11'] = 'yes'
>>> with open('example.ini', 'w') as configfile:
...     config.write(configfile)
... 
```

As you can see, we can treat a config parser much like a dictionary. There are differences, [outlined later](#), but the behavior is very close to what you would expect from a dictionary.

Now that we have created and saved a configuration file, let's read it back and explore the data it holds.

```
>>> config = configparser.ConfigParser()
>>> config.sections()
[]
>>> config.read('example.ini')
['example.ini']
>>> config.sections()
['forge.example', 'topsecret.server.example']
>>> 'forge.example' in config
True
>>> 'python.org' in config
False
>>> config['forge.example']['User']
'hg'
>>> config['DEFAULT']['Compression']
'yes'
>>> topsecret = config['topsecret.server.example']
>>> topsecret['ForwardX11']
'no'
>>> topsecret['Port']
'50022'
>>> for key in config['forge.example']:
...     print(key)
user
compressionlevel
serveraliveinterval
compression
forwardx11
>>> config['forge.example']['ForwardX11']
'yes'
```

As we can see above, the API is pretty straightforward. The only bit of magic involves the `DEFAULT` section which provides default

values for all other sections 1. Note also that keys in sections are case-insensitive and stored in lowercase 1.

It is possible to read several configurations into a single `ConfigParser`, where the most recently added configuration has the highest priority. Any conflicting keys are taken from the more recent configuration while the previously existing keys are retained.

```
>>> another_config = configparser.ConfigParser()
>>> another_config.read('example.ini')
['example.ini']
>>> another_config['topsecret.server.example']['Port']
'50022'
>>> another_config.read_string("[topsecret.server.example]
>>> another_config['topsecret.server.example']['Port']
'48484'
>>> another_config.read_dict({"topsecret.server.example":
>>> another_config['topsecret.server.example']['Port']
'21212'
>>> another_config['topsecret.server.example']['ForwardX']
'no'
```

This behaviour is equivalent to a `ConfigParser.read()` call with several files passed to the *filenames* parameter.

## Supported Datatypes

Config parsers do not guess datatypes of values in configuration files, always storing them internally as strings. This means that if you need other datatypes, you should convert on your own:

```
>>> int(topsecret['Port'])
50022
>>> float(topsecret['CompressionLevel'])
9.0
```

Since this task is so common, config parsers provide a range of handy getter methods to handle integers, floats and booleans. The last one is the most interesting because simply passing the value to `bool()` would do no good since `bool('False')` is still `True`.

This is why config parsers also provide `getboolean()`. This method is case-insensitive and recognizes Boolean values from 'yes'/'no', 'on'/'off', 'true'/'false' and '1'/'0' [1](#). For example:

```
>>> topsecret.getboolean('ForwardX11')
False
>>> config['forge.example'].getboolean('ForwardX11')
True
>>> config.getboolean('forge.example', 'Compression')
True
```

Apart from `getboolean()`, config parsers also provide equivalent `getint()` and `getfloat()` methods. You can register your own converters and customize the provided ones. [1](#)

## Fallback Values

As with a dictionary, you can use a section's `get()` method to provide fallback values:

```
>>> topsecret.get('Port')
'50022'
>>> topsecret.get('CompressionLevel')
'9'
>>> topsecret.get('Cipher')
>>> topsecret.get('Cipher', '3des-cbc')
'3des-cbc'
```

Please note that default values have precedence over fallback values. For instance, in our example the 'CompressionLevel' key was specified only in the 'DEFAULT' section. If we try to get it from the section 'topsecret.server.example', we will always get the default, even if we specify a fallback:

```
>>> topsecret.get('CompressionLevel', '3')
'9'
```

One more thing to be aware of is that the parser-level `get()` method provides a custom, more complex interface, maintained for

backwards compatibility. When using this method, a fallback value can be provided via the `fallback` keyword-only argument:

```
>>> config.get('forge.example', 'monster',  
...           fallback='No such things as monsters')  
'No such things as monsters'
```

The same `fallback` argument can be used with the `getint()`, `getfloat()` and `getboolean()` methods, for example:

```
>>> 'BatchMode' in topsecret  
False  
>>> topsecret.getboolean('BatchMode', fallback=True)  
True  
>>> config['DEFAULT']['BatchMode'] = 'no'  
>>> topsecret.getboolean('BatchMode', fallback=True)  
False
```

## Supported INI File Structure

A configuration file consists of sections, each led by a `[section]` header, followed by key/value entries separated by a specific string (= or : by default [1](#)). By default, section names are case sensitive but keys are not [1](#). Leading and trailing whitespace is removed from keys and values. Values can be omitted if the parser is configured to allow it [1](#), in which case the key/value delimiter may also be left out. Values can also span multiple lines, as long as they are indented deeper than the first line of the value. Depending on the parser's mode, blank lines may be treated as parts of multiline values or ignored.

By default, a valid section name can be any string that does not contain `\n` or `]`. To change this, see [ConfigParser.SECTCRE](#).

Configuration files may include comments, prefixed by specific characters (`#` and `;` by default [1](#)). Comments may appear on their own on an otherwise empty line, possibly indented. [1](#)

For example:

[Simple Values]

key=value

spaces in keys=allowed

spaces in values=allowed as well

spaces around the delimiter = obviously

you can also use : to delimit keys from values

[All Values Are Strings]

values like this: 1000000

or this: 3.14159265359

are they treated as numbers? : no

integers, floats and booleans are held as: strings

can use the API to get converted values directly: true

[Multiline Values]

chorus: I'm a lumberjack, and I'm okay

    I sleep all night and I work all day

[No Values]

key\_without\_value

empty string value here =

[You can use comments]

# like this

; or this

# By default only in an empty line.

# Inline comments can be harmful because they prevent us

# from using the delimiting characters as parts of value

# That being said, this can be customized.

[Sections Can Be Indented]

    can\_values\_be\_as\_well = True

    does\_that\_mean\_anything\_special = False

    purpose = formatting for readability

    multiline\_values = are

        handled just fine as

        long as they are indented

```
        deeper than the first line
        of a value
# Did I mention we can indent comments, too?
```

## Interpolation of values

On top of the core functionality, [ConfigParser](#) supports interpolation. This means values can be preprocessed before returning them from `get()` calls.

*class* `configparser.BasicInterpolation`

The default implementation used by [ConfigParser](#). It enables values to contain format strings which refer to other values in the same section, or values in the special default section 1. Additional default values can be provided on initialization.

For example:

```
[Paths]
home_dir: /Users
my_dir: %(home_dir)s/lumberjack
my_pictures: %(my_dir)s/Pictures

[Escape]
# use a %% to escape the % sign (% is the only char
gain: 80%%
```

In the example above, [ConfigParser](#) with *interpolation* set to `BasicInterpolation()` would resolve `%(home_dir)s` to the value of `home_dir (/Users` in this case). `%(my_dir)s` in effect would resolve to `/Users/lumberjack`. All interpolations are done on demand so keys used in the chain of references do not have to be specified in any specific order in the configuration file.

With *interpolation* set to `None`, the parser would simply return `%(my_dir)s/Pictures` as the value of `my_pictures` and `%(home_dir)s/lumberjack` as the value of `my_dir`.

## *class* configparser.ExtendedInterpolation

An alternative handler for interpolation which implements a more advanced syntax, used for instance in `zc.buildout`. Extended interpolation is using `${section:option}` to denote a value from a foreign section. Interpolation can span multiple levels. For convenience, if the `section:` part is omitted, interpolation defaults to the current section (and possibly the default values from the special section).

For example, the configuration specified above with basic interpolation, would look like this with extended interpolation:

```
[Paths]
home_dir: /Users
my_dir: ${home_dir}/lumberjack
my_pictures: ${my_dir}/Pictures
```

```
[Escape]
# use a $$ to escape the $ sign ($ is the only char
cost: $$80
```

Values from other sections can be fetched as well:

```
[Common]
home_dir: /Users
library_dir: /Library
system_dir: /System
macports_dir: /opt/local
```

```
[Frameworks]
Python: 3.2
path: ${Common:system_dir}/Library/Frameworks/
```

```
[Arthur]
nickname: Two Sheds
last_name: Jackson
my_dir: ${Common:home_dir}/twosheds
my_pictures: ${my_dir}/Pictures
```

```
python_dir: ${Frameworks:path}/Python/Versions/${Fr
```

## Mapping Protocol Access

*New in version 3.2.*

Mapping protocol access is a generic name for functionality that enables using custom objects as if they were dictionaries. In case of [configparser](#), the mapping interface implementation is using the `parser['section']['option']` notation.

`parser['section']` in particular returns a proxy for the section's data in the parser. This means that the values are not copied but they are taken from the original parser on demand. What's even more important is that when values are changed on a section proxy, they are actually mutated in the original parser.

[configparser](#) objects behave as close to actual dictionaries as possible. The mapping interface is complete and adheres to the [MutableMapping](#) ABC. However, there are a few differences that should be taken into account:

- By default, all keys in sections are accessible in a case-insensitive manner [1](#). E.g. for option in `parser["section"]` yields only optionxform'ed option key names. This means lowercased keys by default. At the same time, for a section that holds the key 'a', both expressions return `True`:

```
"a" in parser["section"]  
"A" in parser["section"]
```

- All sections include `DEFAULTSECT` values as well which means that `.clear()` on a section may not leave the section visibly empty. This is because default values cannot be deleted from the section (because technically they are not there). If they are overridden in the section, deleting causes the default value to be visible again. Trying to delete a default value causes a [KeyError](#).

- `DEFAULTSECT` cannot be removed from the parser:
  - trying to delete it raises `ValueError`,
  - `parser.clear()` leaves it intact,
  - `parser.popitem()` never returns it.
- `parser.get(section, option, **kwargs)` - the second argument is **not** a fallback value. Note however that the section-level `get()` methods are compatible both with the mapping protocol and the classic `configparser` API.
- `parser.items()` is compatible with the mapping protocol (returns a list of `section_name`, `section_proxy` pairs including the `DEFAULTSECT`). However, this method can also be invoked with arguments: `parser.items(section, raw, vars)`. The latter call returns a list of `option`, `value` pairs for a specified `section`, with all interpolations expanded (unless `raw=True` is provided).

The mapping protocol is implemented on top of the existing legacy API so that subclasses overriding the original interface still should have mappings working as expected.

## Customizing Parser Behaviour

There are nearly as many INI format variants as there are applications using it. `configparser` goes a long way to provide support for the largest sensible set of INI styles available. The default functionality is mainly dictated by historical background and it's very likely that you will want to customize some of the features.

The most common way to change the way a specific config parser works is to use the `__init__()` options:

- *defaults*, default value: `None`

This option accepts a dictionary of key-value pairs which will be initially put in the `DEFAULT` section. This makes for an elegant way to support concise configuration files that don't specify values which are the same as the documented default.

Hint: if you want to specify default values for a specific section, use `read_dict()` before you read the actual file.

- *dict\_type*, default value: `dict`

This option has a major impact on how the mapping protocol will behave and how the written configuration files look. With the standard dictionary, every section is stored in the order they were added to the parser. Same goes for options within sections.

An alternative dictionary type can be used for example to sort sections and options on write-back.

Please note: there are ways to add a set of key-value pairs in a single operation. When you use a regular dictionary in those operations, the order of the keys will be ordered. For example:

```
>>> parser = configparser.ConfigParser()
>>> parser.read_dict({'section1': {'key1': 'value1',
...                               'key2': 'value2',
...                               'key3': 'value3'},
...                  'section2': {'keyA': 'valueA',
...                               'keyB': 'valueB',
...                               'keyC': 'valueC'},
...                  'section3': {'foo': 'x',
...                               'bar': 'y',
...                               'baz': 'z'}})
>>> parser.sections()
['section1', 'section2', 'section3']
>>> [option for option in parser['section3']]
['foo', 'bar', 'baz']
```

- *allow\_no\_value*, default value: `False`

Some configuration files are known to include settings without values, but which otherwise conform to the syntax supported by `configparser`. The *allow\_no\_value* parameter

to the constructor can be used to indicate that such values should be accepted:

```
>>> import configparser

>>> sample_config = """
... [mysqld]
...     user = mysql
...     pid-file = /var/run/mysqld/mysqld.pid
...     skip-external-locking
...     old_passwords = 1
...     skip-bdb
...     # we don't need ACID today
...     skip-innodb
... """
>>> config = configparser.ConfigParser(allow_no_val
>>> config.read_string(sample_config)

>>> # Settings with values are treated as before:
>>> config["mysqld"]["user"]
'mysql'

>>> # Settings without values provide None:
>>> config["mysqld"]["skip-bdb"]

>>> # Settings which aren't specified still raise a
>>> config["mysqld"]["does-not-exist"]
Traceback (most recent call last):
...
KeyError: 'does-not-exist'
```

- *delimiters*, default value: ('=', ':')

Delimiters are substrings that delimit keys from values within a section. The first occurrence of a delimiting substring on a line is considered a delimiter. This means values (but not keys) can contain the delimiters.

See also the *space\_around\_delimiters* argument to

`ConfigParser.write()`.

- *comment\_prefixes*, default value: ('#', ';')
- *inline\_comment\_prefixes*, default value: None

Comment prefixes are strings that indicate the start of a valid comment within a config file. *comment\_prefixes* are used only on otherwise empty lines (optionally indented) whereas *inline\_comment\_prefixes* can be used after every valid value (e.g. section names, options and empty lines as well). By default inline comments are disabled and '#' and ';' are used as prefixes for whole line comments.

*Changed in version 3.2:* In previous versions of `configparser` behaviour matched `comment_prefixes=('#', ';')` and `inline_comment_prefixes=(';', )`.

Please note that config parsers don't support escaping of comment prefixes so using *inline\_comment\_prefixes* may prevent users from specifying option values with characters used as comment prefixes. When in doubt, avoid setting *inline\_comment\_prefixes*. In any circumstances, the only way of storing comment prefix characters at the beginning of a line in multiline values is to interpolate the prefix, for example:

```
>>> from configparser import ConfigParser, Extended
>>> parser = ConfigParser(interpolation=ExtendedInt
>>> # the default BasicInterpolation could be used
>>> parser.read_string("""
... [DEFAULT]
... hash = #
...
... [hashes]
... shebang =
...     ${hash}!/usr/bin/env python
...     ${hash} -*- coding: utf-8 -*-
...
... extensions =
```

```

...     enabled_extension
...     another_extension
...     #disabled_by_comment
...     yet_another_extension
...
... interpolation not necessary = if # is not at li
... even in multiline values = line #1
...     line #2
...     line #3
...     """
>>> print(parser['hashes']['shebang'])

```

```

#!/usr/bin/env python
# -*- coding: utf-8 -*-
>>> print(parser['hashes']['extensions'])

```

```

enabled_extension
another_extension
yet_another_extension
>>> print(parser['hashes']['interpolation not neces
if # is not at line start
>>> print(parser['hashes']['even in multiline value
line #1
line #2
line #3

```

- *strict*, default value: `True`

When set to `True`, the parser will not allow for any section or option duplicates while reading from a single source (using **`read_file()`**, **`read_string()`** or **`read_dict()`**). It is recommended to use strict parsers in new applications.

*Changed in version 3.2:* In previous versions of **`configparser`** behaviour matched `strict=False`.

- *empty\_lines\_in\_values*, default value: `True`

In config parsers, values can span multiple lines as long as they are indented more than the key that holds them. By

default parsers also let empty lines to be parts of values. At the same time, keys can be arbitrarily indented themselves to improve readability. In consequence, when configuration files get big and complex, it is easy for the user to lose track of the file structure. Take for instance:

```
[Section]
key = multiline
    value with a gotcha

    this = is still a part of the multiline value of '
```

This can be especially problematic for the user to see if she's using a proportional font to edit the file. That is why when your application does not need values with empty lines, you should consider disallowing them. This will make empty lines split keys every time. In the example above, it would produce two keys, `key` and `this`.

- *default\_section*, default value:  
`configparser.DEFAULTSECT` (that is: "DEFAULT")

The convention of allowing a special section of default values for other sections or interpolation purposes is a powerful concept of this library, letting users create complex declarative configurations. This section is normally called "DEFAULT" but this can be customized to point to any other valid section name. Some typical values include: "general" or "common". The name provided is used for recognizing default sections when reading from any source and is used when writing configuration back to a file. Its current value can be retrieved using the `parser_instance.default_section` attribute and may be modified at runtime (i.e. to convert files from one format to another).

- *interpolation*, default value:  
`configparser.BasicInterpolation`

Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. None can

be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the [dedicated documentation section](#). `RawConfigParser` has a default value of `None`.

- *converters*, default value: not set

Config parsers provide option value getters that perform type conversion. By default `getint()`, `getfloat()`, and `getboolean()` are implemented. Should other getters be desirable, users may define them in a subclass or pass a dictionary where each key is a name of the converter and each value is a callable implementing said conversion. For instance, passing `{'decimal': decimal.Decimal}` would add `getdecimal()` on both the parser object and all section proxies. In other words, it will be possible to write both `parser_instance.getdecimal('section', 'key', fallback=0)` and `parser_instance['section'].getdecimal('key', 0)`.

If the converter needs to access the state of the parser, it can be implemented as a method on a config parser subclass. If the name of this method starts with `get`, it will be available on all section proxies, in the dict-compatible form (see the `getdecimal()` example above).

More advanced customization may be achieved by overriding default values of these parser attributes. The defaults are defined on the classes, so they may be overridden by subclasses or by attribute assignment.

### ConfigParser.BOOLEAN\_STATES

By default when using `getboolean()`, config parsers consider the following values `True`: `'1'`, `'yes'`, `'true'`, `'on'` and the following values `False`: `'0'`, `'no'`, `'false'`, `'off'`. You can override this by specifying a custom dictionary of strings and their Boolean outcomes. For example:

```

>>> custom = configparser.ConfigParser()
>>> custom['section1'] = {'funky': 'nope'}
>>> custom['section1'].getboolean('funky')
Traceback (most recent call last):
...
ValueError: Not a boolean: nope
>>> custom.BOOLEAN_STATES = {'sure': True, 'nope':
>>> custom['section1'].getboolean('funky')
False

```

Other typical Boolean pairs include `accept/reject` or `enabled/disabled`.

### `ConfigParser.optionxform(option)`

This method transforms option names on every read, get, or set operation. The default converts the name to lowercase. This also means that when a configuration file gets written, all keys will be lowercase. Override this method if that's unsuitable. For example:

```

>>> config = """
... [Section1]
... Key = Value
...
... [Section2]
... AnotherKey = Value
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> list(typical['Section1'].keys())
['key']
>>> list(typical['Section2'].keys())
['anotherkey']
>>> custom = configparser.RawConfigParser()
>>> custom.optionxform = lambda option: option
>>> custom.read_string(config)
>>> list(custom['Section1'].keys())
['Key']
>>> list(custom['Section2'].keys())

```

```
['AnotherKey']
```

### Note

The `optionxform` function transforms option names to a canonical form. This should be an idempotent function: if the name is already in canonical form, it should be returned unchanged.

### ConfigParser.SECTCRE

A compiled regular expression used to parse section headers. The default matches `[section]` to the name `"section"`. Whitespace is considered part of the section name, thus `[ larch ]` will be read as a section of name `" larch "`. Override this attribute if that's unsuitable. For example:

```
>>> import re
>>> config = """
... [Section 1]
... option = value
...
... [ Section 2 ]
... another = val
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> typical.sections()
['Section 1', ' Section 2 ']
>>> custom = configparser.ConfigParser()
>>> custom.SECTCRE = re.compile(r"\[ *(?P<header>[^\s"]")
>>> custom.read_string(config)
>>> custom.sections()
['Section 1', 'Section 2']
```

### Note

While `ConfigParser` objects also use an `OPTCRE` attribute for recognizing option lines, it's not recommended to

override it because that would interfere with constructor options *allow\_no\_value* and *delimiters*.

## Legacy API Examples

Mainly because of backwards compatibility concerns, **configparser** provides also a legacy API with explicit `get/set` methods. While there are valid use cases for the methods outlined below, mapping protocol access is preferred for new projects. The legacy API is at times more advanced, low-level and downright counterintuitive.

An example of writing to a configuration file:

```
import configparser

config = configparser.RawConfigParser()

# Please note that using RawConfigParser's set functions
# non-string values to keys internally, but will receive
# attempting to write to a file or when you get it in no
# values using the mapping protocol or ConfigParser's se
# such assignments to take place.
config.add_section('Section1')
config.set('Section1', 'an_int', '15')
config.set('Section1', 'a_bool', 'true')
config.set('Section1', 'a_float', '3.1415')
config.set('Section1', 'baz', 'fun')
config.set('Section1', 'bar', 'Python')
config.set('Section1', 'foo', '%(bar)s is %(baz)s!')

# Writing our configuration file to 'example.cfg'
with open('example.cfg', 'w') as configfile:
    config.write(configfile)
```

An example of reading the configuration file again:

```
import configparser
```

```

config = configparser.RawConfigParser()
config.read('example.cfg')

# getfloat() raises an exception if the value is not a float
# getint() and getboolean() also do this for their respective types
a_float = config.getfloat('Section1', 'a_float')
an_int = config.getint('Section1', 'an_int')
print(a_float + an_int)

# Notice that the next output does not interpolate '%(bar)s'
# This is because we are using a RawConfigParser().
if config.getboolean('Section1', 'a_bool'):
    print(config.get('Section1', 'foo'))

```

To get interpolation, use **ConfigParser**:

```

import configparser

cfg = configparser.ConfigParser()
cfg.read('example.cfg')

# Set the optional *raw* argument of get() to True if you want to disable
# interpolation in a single get operation.
print(cfg.get('Section1', 'foo', raw=False)) # -> "Python is fun!"
print(cfg.get('Section1', 'foo', raw=True))  # -> "%(bar)s"

# The optional *vars* argument is a dict with members that override the
# precedence in interpolation.
print(cfg.get('Section1', 'foo', vars={'bar': 'Documentation', 'baz': 'evil'}))

# The optional *fallback* argument can be used to provide a default value.
print(cfg.get('Section1', 'foo'))
# -> "Python is fun!"

print(cfg.get('Section1', 'foo', fallback='Monty is not Python'))
# -> "Python is fun!"

```

```

print(cfg.get('Section1', 'monster', fallback='No such t
# -> "No such things as monsters."

# A bare print(cfg.get('Section1', 'monster')) would raise
# but we can also use:

print(cfg.get('Section1', 'monster', fallback=None))
# -> None

```

Default values are available in both types of ConfigParsers. They are used in interpolation if an option used is not defined elsewhere.

```

import configparser

# New instance with 'bar' and 'baz' defaulting to 'Life'
config = configparser.ConfigParser({'bar': 'Life', 'baz': 'Life'})
config.read('example.cfg')

print(config.get('Section1', 'foo'))      # -> "Python is h
config.remove_option('Section1', 'bar')
config.remove_option('Section1', 'baz')
print(config.get('Section1', 'foo'))      # -> "Life is h

```

## ConfigParser Objects

```

class configparser.ConfigParser(defaults=None, dict_type=dict,
allow_no_value=False, delimiters=('=', ':'), comment_prefixes=(';',
';'), inline_comment_prefixes=None, strict=True,
empty_lines_in_values=True,
default_section=configparser.DEFAULTSECT,
interpolation=BasicInterpolation(), converters={})

```

The main configuration parser. When *defaults* is given, it is initialized into the dictionary of intrinsic defaults. When *dict\_type* is given, it will be used to create the dictionary objects for the list of sections, for the options within a section, and for the default values.

When *delimiters* is given, it is used as the set of substrings that divide keys from values. When *comment\_prefixes* is given, it

will be used as the set of substrings that prefix comments in otherwise empty lines. Comments can be indented. When *inline\_comment\_prefixes* is given, it will be used as the set of substrings that prefix comments in non-empty lines.

When *strict* is `True` (the default), the parser won't allow for any section or option duplicates while reading from a single source (file, string or dictionary), raising `DuplicateSectionError` or `DuplicateOptionError`. When *empty\_lines\_in\_values* is `False` (default: `True`), each empty line marks the end of an option. Otherwise, internal empty lines of a multiline option are kept as part of the value. When *allow\_no\_value* is `True` (default: `False`), options without values are accepted; the value held for these is `None` and they are serialized without the trailing delimiter.

When *default\_section* is given, it specifies the name for the special section holding default values for other sections and interpolation purposes (normally named "DEFAULT"). This value can be retrieved and changed on runtime using the `default_section` instance attribute.

Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. `None` can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the [dedicated documentation section](#).

All option names used in interpolation will be passed through the `optionxform()` method just like any other option name reference. For example, using the default implementation of `optionxform()` (which converts option names to lower case), the values `foo %(bar)s` and `foo %(BAR)s` are equivalent.

When *converters* is given, it should be a dictionary where each key represents the name of a type converter and each value is a callable implementing the conversion from string to the desired datatype. Every converter gets its own corresponding `get*()` method on the parser object and section proxies.

*Changed in version 3.1:* The default `dict_type` is `collections.OrderedDict`.

*Changed in version 3.2:* `allow_no_value`, `delimiters`, `comment_prefixes`, `strict`, `empty_lines_in_values`, `default_section` and `interpolation` were added.

*Changed in version 3.5:* The `converters` argument was added.

*Changed in version 3.7:* The `defaults` argument is read with `read_dict()`, providing consistent behavior across the parser: non-string keys and values are implicitly converted to strings.

*Changed in version 3.8:* The default `dict_type` is `dict`, since it now preserves insertion order.

`defaults()`

Return a dictionary containing the instance-wide defaults.

`sections()`

Return a list of the sections available; the *default section* is not included in the list.

`add_section(section)`

Add a section named *section* to the instance. If a section by the given name already exists, `DuplicateSectionError` is raised. If the *default section* name is passed, `ValueError` is raised. The name of the section must be a string; if not, `TypeError` is raised.

*Changed in version 3.2:* Non-string section names raise `TypeError`.

`has_section(section)`

Indicates whether the named *section* is present in the configuration. The *default section* is not acknowledged.

`options(section)`

Return a list of options available in the specified *section*.

`has_option(section, option)`

If the given *section* exists, and contains the given *option*, return **True**; otherwise return **False**. If the specified *section* is **None** or an empty string, DEFAULT is assumed.

`read(filenamees, encoding=None)`

Attempt to read and parse an iterable of filenames, returning a list of filenames which were successfully parsed.

If *filenamees* is a string, a **bytes** object or a **path-like object**, it is treated as a single filename. If a file named in *filenamees* cannot be opened, that file will be ignored. This is designed so that you can specify an iterable of potential configuration file locations (for example, the current directory, the user's home directory, and some system-wide directory), and all existing configuration files in the iterable will be read.

If none of the named files exist, the **ConfigParser** instance will contain an empty dataset. An application which requires initial values to be loaded from a file should load the required file or files using **read\_file()** before calling **read()** for any optional files:

```
import configparser, os

config = configparser.ConfigParser()
config.read_file(open('defaults.cfg'))
config.read(['site.cfg', os.path.expanduser('~/.config/defaults.cfg'),
            encoding='cp1250'])
```

*New in version 3.2:* The *encoding* parameter. Previously, all files were read using the default encoding for

`open()`.

*New in version 3.6.1:* The *filenames* parameter accepts a [path-like object](#).

*New in version 3.7:* The *filenames* parameter accepts a [bytes](#) object.

`read_file(f, source=None)`

Read and parse configuration data from *f* which must be an iterable yielding Unicode strings (for example files opened in text mode).

Optional argument *source* specifies the name of the file being read. If not given and *f* has a **name** attribute, that is used for *source*; the default is '`<??>`'.

*New in version 3.2:* Replaces [readfp\(\)](#).

`read_string(string, source='<string>')`

Parse configuration data from a string.

Optional argument *source* specifies a context-specific name of the string passed. If not given, '`<string>`' is used. This should commonly be a filesystem path or a URL.

*New in version 3.2.*

`read_dict(dictionary, source='<dict>')`

Load configuration from any object that provides a dict-like `items()` method. Keys are section names, values are dictionaries with keys and values that should be present in the section. If the used dictionary type preserves order, sections and their keys will be added in order. Values are automatically converted to strings.

Optional argument *source* specifies a context-specific name of the dictionary passed. If not given, `<dict>` is

used.

This method can be used to copy state between parsers.

*New in version 3.2.*

`get(section, option, *, raw=False, vars=None[, fallback])`

Get an *option* value for the named *section*. If *vars* is provided, it must be a dictionary. The *option* is looked up in *vars* (if provided), *section*, and in *DEFAULTSECT* in that order. If the key is not found and *fallback* is provided, it is used as a fallback value. *None* can be provided as a *fallback* value.

All the '%' interpolations are expanded in the return values, unless the *raw* argument is true. Values for interpolation keys are looked up in the same manner as the option.

*Changed in version 3.2:* Arguments *raw*, *vars* and *fallback* are keyword only to protect users from trying to use the third argument as the *fallback* fallback (especially when using the mapping protocol).

`getint(section, option, *, raw=False, vars=None[, fallback])`

A convenience method which coerces the *option* in the specified *section* to an integer. See [get\(\)](#) for explanation of *raw*, *vars* and *fallback*.

`getfloat(section, option, *, raw=False, vars=None[, fallback])`

A convenience method which coerces the *option* in the specified *section* to a floating point number. See [get\(\)](#) for explanation of *raw*, *vars* and *fallback*.

`getboolean(section, option, *, raw=False, vars=None[, fallback])`

A convenience method which coerces the *option* in the specified *section* to a Boolean value. Note that the

accepted values for the option are '1', 'yes', 'true', and 'on', which cause this method to return `True`, and '0', 'no', 'false', and 'off', which cause it to return `False`. These string values are checked in a case-insensitive manner. Any other value will cause it to raise `ValueError`. See `get()` for explanation of *raw*, *vars* and *fallback*.

`items(raw=False, vars=None)`

`items(section, raw=False, vars=None)`

When *section* is not given, return a list of *section\_name*, *section\_proxy* pairs, including `DEFAULTSECT`.

Otherwise, return a list of *name*, *value* pairs for the options in the given *section*. Optional arguments have the same meaning as for the `get()` method.

*Changed in version 3.8:* Items present in *vars* no longer appear in the result. The previous behaviour mixed actual parser options with variables provided for interpolation.

`set(section, option, value)`

If the given section exists, set the given option to the specified value; otherwise raise `NoSectionError`. *option* and *value* must be strings; if not, `TypeError` is raised.

`write(fileobject, space_around_delimiters=True)`

Write a representation of the configuration to the specified `file object`, which must be opened in text mode (accepting strings). This representation can be parsed by a future `read()` call. If *space\_around\_delimiters* is true, delimiters between keys and values are surrounded by spaces.

## Note

Comments in the original configuration file are not preserved when writing the configuration back. What is considered a comment, depends on the given values for *comment\_prefix* and *inline\_comment\_prefix*.

`remove_option(section, option)`

Remove the specified *option* from the specified *section*. If the section does not exist, raise `NoSectionError`. If the option existed to be removed, return `True`; otherwise return `False`.

`remove_section(section)`

Remove the specified *section* from the configuration. If the section in fact existed, return `True`. Otherwise return `False`.

`optionxform(option)`

Transforms the option name *option* as found in an input file or as passed in by client code to the form that should be used in the internal structures. The default implementation returns a lower-case version of *option*; subclasses may override this or client code can set an attribute of this name on instances to affect this behavior.

You don't need to subclass the parser to use this method, you can also set it on an instance, to a function that takes a string argument and returns a string. Setting it to `str`, for example, would make option names case sensitive:

```
cfgparser = ConfigParser()
cfgparser.optionxform = str
```

Note that when reading configuration files, whitespace around the option names is stripped before `optionxform()` is called.

`readfp(fp, filename=None)`

*Deprecated since version 3.2:* Use `read_file()` instead.

*Changed in version 3.2:* `readfp()` now iterates on `fp` instead of calling `fp.readline()`.

For existing code calling `readfp()` with arguments which don't support iteration, the following generator may be used as a wrapper around the file-like object:

```
def readline_generator(fp):
    line = fp.readline()
    while line:
        yield line
        line = fp.readline()
```

Instead of `parser.readfp(fp)` use `parser.read_file(readline_generator(fp))`.

`configparser.MAX_INTERPOLATION_DEPTH`

The maximum depth for recursive interpolation for `get()` when the *raw* parameter is false. This is relevant only when the default *interpolation* is used.

## RawConfigParser Objects

`class configparser.RawConfigParser(defaults=None, dict_type=dict, allow_no_value=False, *, delimiters=('=', ':'), comment_prefixes=(';', '#'), inline_comment_prefixes=None, strict=True, empty_lines_in_values=True, default_section=configparser.DEFAULTSECT[, interpolation])`

Legacy variant of the `ConfigParser`. It has interpolation disabled by default and allows for non-string section names, option names, and values via its unsafe `add_section` and `set` methods, as well as the legacy `defaults=` keyword argument handling.

*Changed in version 3.8:* The default `dict_type` is `dict`, since it now preserves insertion order.

### Note

Consider using `ConfigParser` instead which checks types of the values to be stored internally. If you don't want interpolation, you can use `ConfigParser(interpolation=None)`.

### `add_section(section)`

Add a section named *section* to the instance. If a section by the given name already exists, `DuplicateSectionError` is raised. If the *default* section name is passed, `ValueError` is raised.

Type of *section* is not checked which lets users create non-string named sections. This behaviour is unsupported and may cause internal errors.

### `set(section, option, value)`

If the given section exists, set the given option to the specified value; otherwise raise `NoSectionError`. While it is possible to use `RawConfigParser` (or `ConfigParser` with *raw* parameters set to true) for *internal* storage of non-string values, full functionality (including interpolation and output to files) can only be achieved using string values.

This method lets users assign non-string values to keys internally. This behaviour is unsupported and will cause errors when attempting to write to a file or get it in non-raw mode. **Use the mapping protocol API** which does not allow such assignments to take place.

## Exceptions

*exception* `configparser.Error`

Base class for all other `configparser` exceptions.

*exception* `configparser.NoSectionError`

Exception raised when a specified section is not found.

*exception* `configparser.DuplicateSectionError`

Exception raised if `add_section()` is called with the name of a section that is already present or in strict parsers when a section is found more than once in a single input file, string or dictionary.

*New in version 3.2:* Optional `source` and `lineno` attributes and arguments to `__init__()` were added.

*exception* `configparser.DuplicateOptionError`

Exception raised by strict parsers if a single option appears twice during reading from a single file, string or dictionary. This catches misspellings and case sensitivity-related errors, e.g. a dictionary may have two keys representing the same case-insensitive configuration key.

*exception* `configparser.NoOptionError`

Exception raised when a specified option is not found in the specified section.

*exception* `configparser.InterpolationError`

Base class for exceptions raised when problems occur performing string interpolation.

*exception* `configparser.InterpolationDepthError`

Exception raised when string interpolation cannot be completed because the number of iterations exceeds `MAX_INTERPOLATION_DEPTH`. Subclass of `InterpolationError`.

*exception* `configparser.InterpolationMissingOptionError`

Exception raised when an option referenced from a value does not exist. Subclass of `InterpolationError`.

*exception* configparser.InterpolationSyntaxError

Exception raised when the source text into which substitutions are made does not conform to the required syntax. Subclass of [InterpolationError](#).

*exception* configparser.MissingSectionHeaderError

Exception raised when attempting to parse a file which has no section headers.

*exception* configparser.ParsingError

Exception raised when errors occur attempting to parse a file.

*Changed in version 3.2:* The `filename` attribute and `__init__()` argument were renamed to `source` for consistency.

## Footnotes

1([1](#),[2](#),[3](#),[4](#),[5](#),[6](#),[7](#),[8](#),[9](#),[10](#),[11](#))

Config parsers allow for heavy customization. If you are interested in changing the behaviour outlined by the footnote reference, consult the [Customizing Parser Behaviour](#) section.

# tomllib — Parse TOML files

*New in version 3.11.*

**Source code:** [Lib/tomllib](https://github.com/python/cpython/tree/3.11/Lib/tomllib) [https://github.com/python/cpython/tree/3.11/Lib/tomllib]

---

This module provides an interface for parsing TOML (Tom’s Obvious Minimal Language, <https://toml.io> [https://toml.io/en/]). This module does not support writing TOML.

## See also

The [Tomli-W package](https://pypi.org/project/tomli-w/) [https://pypi.org/project/tomli-w/] is a TOML writer that can be used in conjunction with this module, providing a write API familiar to users of the standard library [marshal](#) and [pickle](#) modules.

## See also

The [TOML Kit package](https://pypi.org/project/tomlkit/) [https://pypi.org/project/tomlkit/] is a style-preserving TOML library with both read and write capability. It is a recommended replacement for this module for editing already existing TOML files.

This module defines the following functions:

`tomllib.load(fp, /, *, parse_float=float)`

Read a TOML file. The first argument should be a readable and binary file object. Return a [dict](#). Convert TOML types to Python using this [conversion table](#).

`parse_float` will be called with the string of every TOML float to be decoded. By default, this is equivalent to

`float(num_str)`. This can be used to use another datatype or parser for TOML floats (e.g. `decimal.Decimal`). The callable must not return a `dict` or a `list`, else a `ValueError` is raised.

A `TOMLDecodeError` will be raised on an invalid TOML document.

`tomllib.loads(s, /, *, parse_float=float)`

Load TOML from a `str` object. Return a `dict`. Convert TOML types to Python using this [conversion table](#). The `parse_float` argument has the same meaning as in `load()`.

A `TOMLDecodeError` will be raised on an invalid TOML document.

The following exceptions are available:

*exception* `tomllib.TOMLDecodeError`

Subclass of `ValueError`.

## Examples

Parsing a TOML file:

```
import tomllib
```

```
with open("pyproject.toml", "rb") as f:
    data = tomllib.load(f)
```

Parsing a TOML string:

```
import tomllib
```

```
toml_str = """
python-version = "3.11.0"
python-implementation = "CPython"
"""
```

```
data = tomlllib.loads(toml_str)
```

# Conversion Table

| Python                                                                       | Toml              |
|------------------------------------------------------------------------------|-------------------|

# netrc — netrc file processing

**Source code:** [Lib/netrc.py](#) [<https://github.com/python/cpython/tree/3.11/Lib/netrc.py>]

---

The **netrc** class parses and encapsulates the netrc file format used by the Unix **ftp** program and other FTP clients.

*class netrc.netrc([file])*

A **netrc** instance or subclass instance encapsulates data from a netrc file. The initialization argument, if present, specifies the file to parse. If no argument is given, the file `.netrc` in the user's home directory – as determined by `os.path.expanduser()` – will be read. Otherwise, a `FileNotFoundError` exception will be raised. Parse errors will raise `NetrcParseError` with diagnostic information including the file name, line number, and terminating token. If no argument is specified on a POSIX system, the presence of passwords in the `.netrc` file will raise a `NetrcParseError` if the file ownership or permissions are insecure (owned by a user other than the user running the process, or accessible for read or write by any other user). This implements security behavior equivalent to that of `ftp` and other programs that use `.netrc`.

*Changed in version 3.4:* Added the POSIX permission check.

*Changed in version 3.7:* `os.path.expanduser()` is used to find the location of the `.netrc` file when `file` is not passed as argument.

*Changed in version 3.10:* **netrc** try UTF-8 encoding before using locale specific encoding. The entry in the netrc file no longer needs to contain all tokens. The missing tokens' value default to an empty string. All the tokens and their values

now can contain arbitrary characters, like whitespace and non-ASCII characters. If the login name is anonymous, it won't trigger the security check.

*exception* `netrc.NetrcParseError`

Exception raised by the `netrc` class when syntactical errors are encountered in source text. Instances of this exception provide three interesting attributes: `msg` is a textual explanation of the error, `filename` is the name of the source file, and `lineno` gives the line number on which the error was found.

## netrc Objects

A `netrc` instance has the following methods:

`netrc.authenticators(host)`

Return a 3-tuple (`login`, `account`, `password`) of authenticators for *host*. If the `netrc` file did not contain an entry for the given host, return the tuple associated with the 'default' entry. If neither matching host nor default entry is available, return `None`.

`netrc._repr_()`

Dump the class data as a string in the format of a `netrc` file. (This discards comments and may reorder the entries.)

Instances of `netrc` have public instance variables:

`netrc.hosts`

Dictionary mapping host names to (`login`, `account`, `password`) tuples. The 'default' entry, if any, is represented as a pseudo-host by that name.

`netrc.macros`

Dictionary mapping macro names to string lists.

# `plistlib` — Generate and parse Apple `.plist` files

**Source code:** [Lib/plistlib.py](https://github.com/python/cpython/tree/3.11/Lib/plistlib.py) [https://github.com/python/cpython/tree/3.11/Lib/plistlib.py]

---

This module provides an interface for reading and writing the “property list” files used by Apple, primarily on macOS and iOS. This module supports both binary and XML plist files.

The property list (`.plist`) file format is a simple serialization supporting basic object types, like dictionaries, lists, numbers and strings. Usually the top level object is a dictionary.

To write out and to parse a plist file, use the `dump()` and `load()` functions.

To work with plist data in bytes objects, use `dumps()` and `loads()`.

Values can be strings, integers, floats, booleans, tuples, lists, dictionaries (but only with string keys), `bytes`, `bytearray` or `datetime.datetime` objects.

*Changed in version 3.4:* New API, old API deprecated. Support for binary format plists added.

*Changed in version 3.8:* Support added for reading and writing `UUID` tokens in binary plists as used by `NSKeyedArchiver` and `NSKeyedUnarchiver`.

*Changed in version 3.9:* Old API removed.

**See also**

[PList manual page](https://developer.apple.com/library/archive/documentation/Cocoa/Conceptual/PropertyLists/) [https://developer.apple.com/library/archive/documentation/Cocoa/Conceptual/PropertyLists/]

Apple's documentation of the file format.

This module defines the following functions:

`plistlib.load(fp, *, fmt=None, dict_type=dict)`

Read a plist file. *fp* should be a readable and binary file object. Return the unpacked root object (which usually is a dictionary).

The *fmt* is the format of the file and the following values are valid:

- **None**: Autodetect the file format
- **FMT\_XML**: XML file format
- **FMT\_BINARY**: Binary plist format

The *dict\_type* is the type used for dictionaries that are read from the plist file.

XML data for the **FMT\_XML** format is parsed using the Expat parser from `xml.parsers.expat` – see its documentation for possible exceptions on ill-formed XML. Unknown elements will simply be ignored by the plist parser.

The parser for the binary format raises **InvalidFileException** when the file cannot be parsed.

*New in version 3.4.*

`plistlib.loads(data, *, fmt=None, dict_type=dict)`

Load a plist from a bytes object. See `load()` for an explanation of the keyword arguments.

*New in version 3.4.*

`plistlib.dump(value, fp, *, fmt=FMT_XML, sort_keys=True, skipkeys=False)`

Write *value* to a plist file. *Fp* should be a writable, binary file object.

The *fmt* argument specifies the format of the plist file and can be one of the following values:

- **FMT\_XML**: XML formatted plist file
- **FMT\_BINARY**: Binary formatted plist file

When *sort\_keys* is true (the default) the keys for dictionaries will be written to the plist in sorted order, otherwise they will be written in the iteration order of the dictionary.

When *skipkeys* is false (the default) the function raises **TypeError** when a key of a dictionary is not a string, otherwise such keys are skipped.

A **TypeError** will be raised if the object is of an unsupported type or a container that contains objects of unsupported types.

An **OverflowError** will be raised for integer values that cannot be represented in (binary) plist files.

*New in version 3.4.*

```
plistlib.dumps(value, *, fmt=FMT_XML, sort_keys=True,  
skipkeys=False)
```

Return *value* as a plist-formatted bytes object. See the documentation for **dump()** for an explanation of the keyword arguments of this function.

*New in version 3.4.*

The following classes are available:

```
class plistlib.UID(data)
```

Wraps an **int**. This is used when reading or writing NSKeyedArchiver encoded data, which contains UID (see PList manual).

It has one attribute, **data**, which can be used to retrieve the int value of the UID. **data** must be in the range  $0 \leq \text{data} < 2^{64}$ .

*New in version 3.8.*

The following constants are available:

`plistlib.FMT_XML`

The XML format for plist files.

*New in version 3.4.*

`plistlib.FMT_BINARY`

The binary format for plist files

*New in version 3.4.*

## Examples

Generating a plist:

```
import datetime
import plistlib

pl = dict(
    aString = "Doodah",
    aList = ["A", "B", 12, 32.1, [1, 2, 3]],
    aFloat = 0.1,
    anInt = 728,
    aDict = dict(
        anotherString = "<hello & hi there!>",
        aThirdString = "M\xe4ssig, Ma\xdf",
        aTrueValue = True,
        aFalseValue = False,
    ),
    someData = b"<binary gunk>",
    someMoreData = b"<lots of binary gunk>" * 10,
    aDate = datetime.datetime.now())
```

```
)  
print(plistlib.dumps(pl).decode())
```

### Parsing a plist:

```
import plistlib  
  
plist = b"<plist version='1.0'>  
<dict>  
    <key>foo</key>  
    <string>bar</string>  
</dict>  
</plist>"  
pl = plistlib.loads(plist)  
print(pl["foo"])
```

# Cryptographic Services

The modules described in this chapter implement various algorithms of a cryptographic nature. They are available at the discretion of the installation. On Unix systems, the **crypt** module may also be available. Here's an overview:

- **hashlib** — Secure hashes and message digests

- Hash algorithms
- Usage
- Constructors
- Attributes
- Hash Objects
- SHAKE variable length digests
- File hashing
- Key derivation
- BLAKE2

- Creating hash objects

- Constants

- Examples

- Simple hashing

- Using different digest sizes

- Keyed hashing

- Randomized hashing

- Personalization

- Tree mode

- Credits

- **hmac** — Keyed-Hashing for Message Authentication
- **secrets** — Generate secure random numbers for managing secrets
  - Random numbers

- Generating tokens

- How many bytes should tokens use?

- Other functions

- Recipes and best practices

# hashlib — Secure hashes and message digests

**Source code:** [Lib/hashlib.py](https://github.com/python/cpython/tree/3.11/Lib/hashlib.py) [https://github.com/python/cpython/tree/3.11/Lib/hashlib.py]

This module implements a common interface to many different secure hash and message digest algorithms. Included are the FIPS secure hash algorithms SHA1, SHA224, SHA256, SHA384, SHA512, (defined in [the FIPS 180-4 standard](https://csrc.nist.gov/publications/detail/fips/180/4/final) [https://csrc.nist.gov/publications/detail/fips/180/4/final]), the SHA-3 series (defined in [the FIPS 202 standard](https://csrc.nist.gov/publications/detail/fips/202/final) [https://csrc.nist.gov/publications/detail/fips/202/final]) as well as RSA’s MD5 algorithm (defined in internet [RFC 1321](https://datatracker.ietf.org/doc/html/rfc1321.html) [https://datatracker.ietf.org/doc/html/rfc1321.html]). The terms “secure hash” and “message digest” are interchangeable. Older algorithms were called message digests. The modern term is secure hash.

## Note

If you want the `adler32` or `crc32` hash functions, they are

available in the `zlib` module.

## Hash algorithms

There is one constructor method named for each type of *hash*. All return a hash object with the same simple interface. For example: use `sha256()` to create a SHA-256 hash object. You can now feed this object with *bytes-like objects* (normally `bytes`) using the `update` method. At any point you can ask it for the *digest* of the concatenation of the data fed to it so far using the `digest()` or `hexdigest()` methods.

To allow multithreading, the Python `GIL` is released while computing a hash supplied more than 2047 bytes of data at once in its constructor or `.update` method.

Constructors for hash algorithms that are always present in this module are `sha1()`, `sha224()`, `sha256()`, `sha384()`, `sha512()`, `sha3_224()`, `sha3_256()`, `sha3_384()`, `sha3_512()`, `shake_128()`, `shake_256()`, `blake2b()`, and `blake2s()`. `md5()` is normally available as well, though it may be missing or blocked if you are using a rare “FIPS compliant” build of Python. These correspond to `algorithms_guaranteed`.

Additional algorithms may also be available if your Python distribution’s `hashlib` was linked against a build of OpenSSL that provides others. Others *are not guaranteed available* on all installations and will only be accessible by name via `new()`. See `algorithms_available`.

### Warning

Some algorithms have known hash collision weaknesses (including MD5 and SHA1). Refer to [Attacks on cryptographic hash algorithms](https://en.wikipedia.org/wiki/Cryptographic_hash_function#Attacks_on_cryptographic_hash_algorithms) [https://en.wikipedia.org/wiki/

Cryptographic\_hash\_function#Attacks\_on\_cryptographic\_hash\_algorithms] and the `hashlib-seealso` section at the end of this document.

*New in version 3.6:* SHA3 (Keccak) and SHAKE constructors

`sha3_224()`, `sha3_256()`, `sha3_384()`, `sha3_512()`, `shake_128()`, `shake_256()` were added.

*New in version 3.6:* `blake2b()` and `blake2s()` were added.

*Changed in version 3.9:* All hashlib constructors take a keyword-only argument *usedforsecurity* with default value `True`. A false value allows the use of insecure and blocked hashing algorithms in restricted environments. `False` indicates that the hashing algorithm is not used in a security context, e.g. as a non-cryptographic one-way compression function.

*Changed in version 3.9:* Hashlib now uses SHA3 and SHAKE from OpenSSL if it provides it.

## Usage

To obtain the digest of the byte string `b"Nobody inspects the spammish repetition"`:

```
>>> import hashlib
>>> m = hashlib.sha256()
>>> m.update(b"Nobody inspects")
>>> m.update(b" the spammish repetition")
>>> m.digest()
b'\x03\x1e\xdd}Ae\x15\x93\xc5\xfe\\\x00o\xa5u+7\xfd\xdf\x'
>>> m.hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fdddf7bc4e843aa6af0c9'
```

More condensed:

```
>>> hashlib.sha256(b"Nobody inspects the spammish repetition").hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fdddf7bc4e843aa6af0c9'

```

# Constructors

```
hashlib.new(name, [data, ]\*, usedforsecurity=True)
```

Is a generic constructor that takes the string *name* of the desired algorithm as its first parameter. It also exists to allow

access to the above listed hashes as well as any other algorithms that your OpenSSL library may offer.

Using `new()` with an algorithm name:

```
>>> h = hashlib.new('sha256')
>>> h.update(b"Nobody inspects the spammish repetition")
>>> h.hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fddff7bc4e843aa6af0c9'
```

```
hashlib.md5([data, ]\*, usedforsecurity=True)
```

```
hashlib.sha1([data, ]\*, usedforsecurity=True)
```

```
hashlib.sha224([data, ]\*, usedforsecurity=True)
```

```
hashlib.sha256([data, ]\*, usedforsecurity=True)
```

```
hashlib.sha384([data, ]\*, usedforsecurity=True)
```

```
hashlib.sha512([data, ]\*, usedforsecurity=True)
```

```
hashlib.sha3_224([data, ]\*, usedforsecurity=True)
```

```
hashlib.sha3_256([data, ]\*, usedforsecurity=True)
```

```
hashlib.sha3_384([data, ]\*, usedforsecurity=True)
```

```
hashlib.sha3_512([data, ]\*, usedforsecurity=True)
```

Named constructors such as these are faster than passing an algorithm name to `new()`.

## Attributes

Hashlib provides the following constant module attributes:

`hashlib.algorithms_guaranteed`

A set containing the names of the hash algorithms guaranteed to be supported by this module on all platforms. Note that ‘md5’ is in this list despite some upstream vendors offering an odd “FIPS compliant” Python build that excludes it.

*New in version 3.2.*

`hashlib.algorithms_available`

A set containing the names of the hash algorithms that are available in the running Python interpreter. These names will be recognized when passed to `new()`.

`algorithms_guaranteed` will always be a subset. The same algorithm may appear multiple times in this set under different names (thanks to OpenSSL).

*New in version 3.2.*

## Hash Objects

The following values are provided as constant attributes of the hash objects returned by the constructors:

`hash.digest_size`

The size of the resulting hash in bytes.

`hash.block_size`

The internal block size of the hash algorithm in bytes.

A hash object has the following attributes:

`hash.name`

The canonical name of this hash, always lowercase and always suitable as a parameter to `new()` to create another hash of this type.

*Changed in version 3.4:* The name attribute has been present in

CPython since its inception, but until Python 3.4 was not formally specified, so may not exist on some platforms.

A hash object has the following methods:

`hash.update(data)`

Update the hash object with the [bytes-like object](#). Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a+b)`.

*Changed in version 3.1:* The Python GIL is released to allow other threads to run while hash updates on data larger than 2047 bytes is taking place when using hash algorithms supplied by OpenSSL.

`hash.digest()`

Return the digest of the data passed to the [update\(\)](#) method so far. This is a bytes object of size [digest\\_size](#) which may contain bytes in the whole range from 0 to 255.

`hash.hexdigest()`

Like [digest\(\)](#) except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

`hash.copy()`

Return a copy (“clone”) of the hash object. This can be used to efficiently compute the digests of data sharing a common initial substring.

## SHAKE variable length digests

`hashlib.shake_128([data, ]\*, usedforsecurity=True)`

`hashlib.shake_256([data, ]\*, usedforsecurity=True)`

The `shake_128()` and `shake_256()` algorithms provide variable length digests with `length_in_bits//2` up to 128 or 256 bits of security. As such, their digest methods require a length. Maximum length is not limited by the SHAKE algorithm.

`shake.digest(length)`

Return the digest of the data passed to the `update()` method so far. This is a bytes object of size `length` which may contain bytes in the whole range from 0 to 255.

`shake.hexdigest(length)`

Like `digest()` except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value in email or other non-binary environments.

Example use:

```
>>> h = hashlib.shake_256(b'Nobody inspects the spammish  
>>> h.hexdigest(20)  
'44709d6fcb83d92a76dcb0b668c98e1b1d3dafa7')
```

## File hashing

The `hashlib` module provides a helper function for efficient hashing of a file or file-like object.

`hashlib.file_digest(fileobj, digest, /)`

Return a digest object that has been updated with contents of file object.

*fileobj* must be a file-like object opened for reading in binary mode. It accepts file objects from builtin `open()`, `BytesIO` instances, `SocketIO` objects from `socket.socket.makefile()`, and similar. The function may bypass Python's I/O and use the file descriptor from `fileno()` directly. *fileobj* must be assumed to be in an unknown state after this function returns or raises. It is up to

the caller to close *fileobj*.

*digest* must either be a hash algorithm name as a *str*, a hash constructor, or a callable that returns a hash object.

Example:

```
>>> import io, hashlib, hmac
>>> with open(hashlib.__file__, "rb") as f:
...     digest = hashlib.file_digest(f, "sha256")
...
>>> digest.hexdigest()
'...'

>>> buf = io.BytesIO(b"somedata")
>>> mac1 = hmac.HMAC(b"key", digestmod=hashlib.sha5
>>> digest = hashlib.file_digest(buf, lambda: mac1)

>>> digest is mac1
True
>>> mac2 = hmac.HMAC(b"key", b"somedata", digestmod
>>> mac1.digest() == mac2.digest()
True
```

*New in version 3.11.*

## Key derivation

Key derivation and key stretching algorithms are designed for secure password hashing. Naive algorithms such as `sha1(password)` are not resistant against brute-force attacks. A good password hashing function must be tunable, slow, and include a [salt](https://en.wikipedia.org/wiki/Salt_%28cryptography%29) [https://en.wikipedia.org/wiki/Salt\_%28cryptography%29].

`hashlib.pbkdf2_hmac(hash_name, password, salt, iterations, dklen=None)`

The function provides PKCS#5 password-based key derivation function 2. It uses HMAC as pseudorandom function.

The string *hash\_name* is the desired name of the hash digest algorithm for HMAC, e.g. 'sha1' or 'sha256'. *password* and *salt* are interpreted as buffers of bytes. Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. `os.urandom()`.

The number of *iterations* should be chosen based on the hash algorithm and computing power. As of 2022, hundreds of thousands of iterations of SHA-256 are suggested. For rationale as to why and how to choose what is best for your application, read *Appendix A.2.2* of [NIST-SP-800-132](https://nvlpubs.nist.gov/nistpubs/Legacy/SP/nistspecialpublication800-132.pdf) [https://nvlpubs.nist.gov/nistpubs/Legacy/SP/nistspecialpublication800-132.pdf]. The answers on the [stackexchange pbkdf2 iterations question](https://security.stackexchange.com/questions/3959/recommended-of-iterations-when-using-pbkdf2-sha256/) [https://security.stackexchange.com/questions/3959/recommended-of-iterations-when-using-pbkdf2-sha256/] explain in detail.

*dklen* is the length of the derived key. If *dklen* is `None` then the digest size of the hash algorithm *hash\_name* is used, e.g. 64 for SHA-512.

```
>>> from hashlib import pbkdf2_hmac
>>> our_app_iters = 500_000 # Application specific
>>> dk = pbkdf2_hmac('sha256', b'password', b'bad s
>>> dk.hex()
'15530bba69924174860db778f2c6f8104d3aaf9d26241840c8'
```

*New in version 3.4.*

### Note

A fast implementation of *pbkdf2\_hmac* is available with OpenSSL. The Python implementation uses an inline version of [hmac](#). It is about three times slower and doesn't release the GIL.

*Deprecated since version 3.10:* Slow Python implementation of *pbkdf2\_hmac* is deprecated. In the future the function will only be available when Python is compiled with OpenSSL.

`hashlib.scrypt(password, *, salt, n, r, p, maxmem=0, dklen=64)`

The function provides scrypt password-based key derivation function as defined in [RFC 7914](https://datatracker.ietf.org/doc/html/rfc7914.html) [https://datatracker.ietf.org/doc/html/rfc7914.html].

*password* and *salt* must be [bytes-like objects](#). Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. `os.urandom()`.

*n* is the CPU/Memory cost factor, *r* the block size, *p* parallelization factor and *maxmem* limits memory (OpenSSL 1.1.0 defaults to 32 MiB). *dklen* is the length of the derived key.

*New in version 3.6.*

## BLAKE2

[BLAKE2](https://www.blake2.net) [https://www.blake2.net] is a cryptographic hash function defined in [RFC 7693](https://datatracker.ietf.org/doc/html/rfc7693.html) [https://datatracker.ietf.org/doc/html/rfc7693.html] that comes in two flavors:

- **BLAKE2b**, optimized for 64-bit platforms and produces digests of any size between 1 and 64 bytes,
- **BLAKE2s**, optimized for 8- to 32-bit platforms and produces digests of any size between 1 and 32 bytes.

BLAKE2 supports **keyed mode** (a faster and simpler replacement for [HMAC](https://en.wikipedia.org/wiki/Hash-based_message_authentication_code) [https://en.wikipedia.org/wiki/Hash-based\_message\_authentication\_code]), **salted hashing**, **personalization**, and **tree hashing**.

Hash objects from this module follow the API of standard library's [hashlib](#) objects.

## Creating hash objects

New hash objects are created by calling constructor functions:

```
hashlib.blake2b(data=b", *, digest_size=64, key=b", salt=b",
person=b", fanout=1, depth=1, leaf_size=0, node_offset=0,
node_depth=0, inner_size=0, last_node=False, usedforsecurity=True)
```

```
hashlib.blake2s(data=b", *, digest_size=32, key=b", salt=b",
person=b", fanout=1, depth=1, leaf_size=0, node_offset=0,
node_depth=0, inner_size=0, last_node=False, usedforsecurity=True)
```

These functions return the corresponding hash objects for calculating BLAKE2b or BLAKE2s. They optionally take these general parameters:

- *data*: initial chunk of data to hash, which must be [bytes-like object](#). It can be passed only as positional argument.
- *digest\_size*: size of output digest in bytes.
- *key*: key for keyed hashing (up to 64 bytes for BLAKE2b, up to 32 bytes for BLAKE2s).
- *salt*: salt for randomized hashing (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).
- *person*: personalization string (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).

The following table shows limits for general parameters (in bytes):

| Parameter |
|-----------|
| BLAKE2b   |
| BLAKE2s   |

**Note**

BLAKE2 specification defines constant lengths for salt and personalization parameters, however, for convenience, this implementation accepts byte strings of any size up to the specified length. If the length of the parameter is less than specified, it is padded with zeros, thus, for example, `b'salt'` and `b'salt\x00'` is the same value. (This is not the case for *key*.)

These sizes are available as module [constants](#) described below.

Constructor functions also accept the following tree hashing parameters:

- *fanout*: fanout (0 to 255, 0 if unlimited, 1 in sequential mode).
- *depth*: maximal depth of tree (1 to 255, 255 if unlimited, 1 in sequential mode).
- *leaf\_size*: maximal byte length of leaf (0 to  $2^{32}-1$ , 0 if unlimited or in sequential mode).
- *node\_offset*: node offset (0 to  $2^{64}-1$  for BLAKE2b, 0 to  $2^{48}-1$  for BLAKE2s, 0 for the first, leftmost, leaf, or in sequential mode).
- *node\_depth*: node depth (0 to 255, 0 for leaves, or in sequential mode).
- *inner\_size*: inner digest size (0 to 64 for BLAKE2b, 0 to 32 for BLAKE2s, 0 in sequential mode).
- *last\_node*: boolean indicating whether the processed node is the last one (`False` for sequential mode).

See section 2.10 in [BLAKE2 specification](https://www.blake2.net/blake2_20130129.pdf) [https://www.blake2.net/blake2\_20130129.pdf] for comprehensive review of tree hashing.

## Constants

blake2b.SALT\_SIZE

blake2s.SALT\_SIZE

Salt length (maximum length accepted by constructors).

blake2b.PERSON\_SIZE

blake2s.PERSON\_SIZE

Personalization string length (maximum length accepted by constructors).

blake2b.MAX\_KEY\_SIZE

blake2s.MAX\_KEY\_SIZE

Maximum key size.

`blake2b.MAX_DIGEST_SIZE`

`blake2s.MAX_DIGEST_SIZE`

Maximum digest size that the hash function can output.

## Examples

### Simple hashing

To calculate hash of some data, you should first construct a hash object by calling the appropriate constructor function (`blake2b()` or `blake2s()`), then update it with the data by calling `update()` on the object, and, finally, get the digest out of the object by calling `digest()` (or `hexdigest()` for hex-encoded string).

```
>>> from hashlib import blake2b
>>> h = blake2b()
>>> h.update(b'Hello world')
>>> h.hexdigest()
'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c1'
```

As a shortcut, you can pass the first chunk of data to update directly to the constructor as the positional argument:

```
>>> from hashlib import blake2b
>>> blake2b(b'Hello world').hexdigest()
'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c1'
```

You can call `hash.update()` as many times as you need to iteratively update the hash:

```
>>> from hashlib import blake2b
>>> items = [b'Hello', b' ', b'world']
>>> h = blake2b()
>>> for item in items:
...     h.update(item)
>>> h.hexdigest()
```

```
'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c1'
```

## Using different digest sizes

BLAKE2 has configurable size of digests up to 64 bytes for BLAKE2b and up to 32 bytes for BLAKE2s. For example, to replace SHA-1 with BLAKE2b without changing the size of output, we can tell BLAKE2b to produce 20-byte digests:

```
>>> from hashlib import blake2b
>>> h = blake2b(digest_size=20)
>>> h.update(b'Replacing SHA1 with the more secure funct
>>> h.hexdigest()
'd24f26cf8de66472d58d4e1b1774b4c9158b1f4c'
>>> h.digest_size
20
>>> len(h.digest())
20
```

Hash objects with different digest sizes have completely different outputs (shorter hashes are *not* prefixes of longer hashes); BLAKE2b and BLAKE2s produce different outputs even if the output length is the same:

```
>>> from hashlib import blake2b, blake2s
>>> blake2b(digest_size=10).hexdigest()
'6fal8f8cf8d719046d762'
>>> blake2b(digest_size=11).hexdigest()
'eb6ec15daf9546254f0809'
>>> blake2s(digest_size=10).hexdigest()
'1bf21a98c78a1c376ae9'
>>> blake2s(digest_size=11).hexdigest()
'567004bf96e4a25773ebf4'
```

## Keyed hashing

Keyed hashing can be used for authentication as a faster and simpler replacement for [Hash-based message authentication code](https://en.wikipedia.org/wiki/HMAC) [https://en.wikipedia.org/wiki/HMAC] (HMAC). BLAKE2 can be securely

used in prefix-MAC mode thanks to the indifferentiability property inherited from BLAKE.

This example shows how to get a (hex-encoded) 128-bit authentication code for message `b'message data'` with key `b'pseudorandom key'`:

```
>>> from hashlib import blake2b
>>> h = blake2b(key=b'pseudorandom key', digest_size=16)
>>> h.update(b'message data')
>>> h.hexdigest()
'3d363ff7401e02026f4a4687d4863ced'
```

As a practical example, a web application can symmetrically sign cookies sent to users and later verify them to make sure they weren't tampered with:

```
>>> from hashlib import blake2b
>>> from hmac import compare_digest
>>>
>>> SECRET_KEY = b'pseudorandomly generated server secret'
>>> AUTH_SIZE = 16
>>>
>>> def sign(cookie):
...     h = blake2b(digest_size=AUTH_SIZE, key=SECRET_KEY)
...     h.update(cookie)
...     return h.hexdigest().encode('utf-8')
>>>
>>> def verify(cookie, sig):
...     good_sig = sign(cookie)
...     return compare_digest(good_sig, sig)
>>>
>>> cookie = b'user-alice'
>>> sig = sign(cookie)
>>> print("{0},{1}".format(cookie.decode('utf-8'), sig))
user-alice,b'43b3c982cf697e0c5ab22172d1ca7421'
>>> verify(cookie, sig)
True
>>> verify(b'user-bob', sig)
```

```
False
>>> verify(cookie, b'0102030405060708090a0b0c0d0e0f00')
False
```

Even though there's a native keyed hashing mode, BLAKE2 can, of course, be used in HMAC construction with `hmac` module:

```
>>> import hmac, hashlib
>>> m = hmac.new(b'secret key', digestmod=hashlib.blake2b)
>>> m.update(b'message')
>>> m.hexdigest()
'e3c8102868d28b5ff85fc35dda07329970d1a01e273c37481326fe0'
```

## Randomized hashing

By setting *salt* parameter users can introduce randomization to the hash function. Randomized hashing is useful for protecting against collision attacks on the hash function used in digital signatures.

Randomized hashing is designed for situations where one party, the message preparer, generates all or part of a message to be signed by a second party, the message signer. If the message preparer is able to find cryptographic hash function collisions (i.e., two messages producing the same hash value), then they might prepare meaningful versions of the message that would produce the same hash value and digital signature, but with different results (e.g., transferring \$1,000,000 to an account, rather than \$10). Cryptographic hash functions have been designed with collision resistance as a major goal, but the current concentration on attacking cryptographic hash functions may result in a given cryptographic hash function providing less collision resistance than expected. Randomized hashing offers the signer additional protection by reducing the likelihood that a preparer can generate two or more messages that ultimately yield the same hash value during the digital signature generation process — even if it

is practical to find collisions for the hash function. However, the use of randomized hashing may reduce the amount of security provided by a digital signature when all portions of the message are prepared by the signer.

(NIST SP-800-106 “Randomized Hashing for Digital Signatures” [<https://csrc.nist.gov/publications/detail/sp/800-106/archive/2009-02-25>])

In BLAKE2 the salt is processed as a one-time input to the hash function during initialization, rather than as an input to each compression function.

## Warning

*Salted hashing* (or just hashing) with BLAKE2 or any other general-purpose cryptographic hash function, such as SHA-256, is not suitable for hashing passwords. See [BLAKE2 FAQ](https://www.blake2.net/#qa) [<https://www.blake2.net/#qa>] for more information.

```
>>> import os
>>> from hashlib import blake2b
>>> msg = b'some message'
>>> # Calculate the first hash with a random salt.
>>> salt1 = os.urandom(blake2b.SALT_SIZE)
>>> h1 = blake2b(salt=salt1)
>>> h1.update(msg)
>>> # Calculate the second hash with a different random
>>> salt2 = os.urandom(blake2b.SALT_SIZE)
>>> h2 = blake2b(salt=salt2)
>>> h2.update(msg)
>>> # The digests are different.
>>> h1.digest() != h2.digest()
True
```

## Personalization

Sometimes it is useful to force hash function to produce different

digests for the same input for different purposes. Quoting the authors of the Skein hash function:

We recommend that all application designers seriously consider doing this; we have seen many protocols where a hash that is computed in one part of the protocol can be used in an entirely different part because two hash computations were done on similar or related data, and the attacker can force the application to make the hash inputs the same. Personalizing each hash function used in the protocol summarily stops this type of attack.

([The Skein Hash Function Family](https://www.schneier.com/wp-content/uploads/2016/02/skein.pdf) [https://www.schneier.com/wp-content/uploads/2016/02/skein.pdf], p. 21)

BLAKE2 can be personalized by passing bytes to the *person* argument:

```
>>> from hashlib import blake2b
>>> FILES_HASH_PERSON = b'MyApp Files Hash'
>>> BLOCK_HASH_PERSON = b'MyApp Block Hash'
>>> h = blake2b(digest_size=32, person=FILES_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'20d9cd024d4fb086aae819a1432dd2466de12947831b75c5a30cf26
>>> h = blake2b(digest_size=32, person=BLOCK_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'cf68fb5761b9c44e7878bfb2c4c9aea52264a80b75005e65619778c
```

Personalization together with the keyed mode can also be used to derive different keys from a single one.

```
>>> from hashlib import blake2s
>>> from base64 import b64decode, b64encode
>>> orig_key = b64decode(b'Rm5EPJai72qcK3RGBpW3vPNfZy50Z')
>>> enc_key = blake2s(key=orig_key, person=b'kEncrypt').digest()
>>> mac_key = blake2s(key=orig_key, person=b'kMAC').digest()
```

```
>>> print(b64encode(enc_key).decode('utf-8'))
rbPb15S/Z9t+agffno5wuhB77VbRi6F9Iv2qIxU7WHw=
>>> print(b64encode(mac_key).decode('utf-8'))
G9GtHFE1YluXY1zWP1Yk1e/nWfu0WSEb0KRcjhDeP/o=
```

## Tree mode

Here's an example of hashing a minimal tree with two leaf nodes:

```
    10
   /  \
  00   01
```

This example uses 64-byte internal digests, and returns the 32-byte final digest:

```
>>> from hashlib import blake2b
>>>
>>> FANOUT = 2
>>> DEPTH = 2
>>> LEAF_SIZE = 4096
>>> INNER_SIZE = 64
>>>
>>> buf = bytearray(6000)
>>>
>>> # Left leaf
... h00 = blake2b(buf[0:LEAF_SIZE], fanout=FANOUT, depth=
...         leaf_size=LEAF_SIZE, inner_size=INNER_
...         node_offset=0, node_depth=0, last_node
>>> # Right leaf
... h01 = blake2b(buf[LEAF_SIZE:], fanout=FANOUT, depth=
...         leaf_size=LEAF_SIZE, inner_size=INNER_
...         node_offset=1, node_depth=0, last_node
>>> # Root node
... h10 = blake2b(digest_size=32, fanout=FANOUT, depth=D
...         leaf_size=LEAF_SIZE, inner_size=INNER_
...         node_offset=0, node_depth=1, last_node
>>> h10.update(h00.digest())
>>> h10.update(h01.digest())
```

```
>>> h10.hexdigest()  
'3ad2a9b37c6070e374c7a8c508fe20ca86b6ed54e286e93a0318e95'
```

## Credits

**BLAKE2** [<https://www.blake2.net>] was designed by *Jean-Philippe Aumasson, Samuel Neves, Zooko Wilcox-O'Hearn, and Christian Winnerlein* based on **SHA-3** [[https://en.wikipedia.org/wiki/Secure\\_Hash\\_Algorithms](https://en.wikipedia.org/wiki/Secure_Hash_Algorithms)] finalist **BLAKE** [<https://web.archive.org/web/20200918190133/https://131002.net/blake/>] created by *Jean-Philippe Aumasson, Luca Henzen, Willi Meier, and Raphael C.-W. Phan*.

It uses core algorithm from **ChaCha** [<https://cr.yp.to/chacha.html>] cipher designed by *Daniel J. Bernstein*.

The stdlib implementation is based on **pyblake2** [<https://pythonhosted.org/pyblake2/>] module. It was written by *Dmitry Chestnykh* based on C implementation written by *Samuel Neves*. The documentation was copied from **pyblake2** [<https://pythonhosted.org/pyblake2/>] and written by *Dmitry Chestnykh*.

The C code was partly rewritten for Python by *Christian Heimes*.

The following public domain dedication applies for both C hash function implementation, extension code, and this documentation:

# hmac — Keyed-Hashing for Message Authentication

**Source code:** [Lib/hmac.py](https://github.com/python/cpython/tree/3.11/Lib/hmac.py) [https://github.com/python/cpython/tree/3.11/Lib/hmac.py]

---

This module implements the HMAC algorithm as described by [RFC 2104](https://datatracker.ietf.org/doc/html/rfc2104.html) [https://datatracker.ietf.org/doc/html/rfc2104.html].

`hmac.new(key, msg=None, digestmod="")`

Return a new hmac object. *key* is a bytes or bytearray object giving the secret key. If *msg* is present, the method call `update(msg)` is made. *digestmod* is the digest name, digest constructor or module for the HMAC object to use. It may be any name suitable to `hashlib.new()`. Despite its argument position, it is required.

*Changed in version 3.4:* Parameter *key* can be a bytes or bytearray object. Parameter *msg* can be of any type supported by `hashlib`. Parameter *digestmod* can be the name of a hash algorithm.

*Deprecated since version 3.4, removed in version 3.8:* MD5 as implicit default digest for *digestmod* is deprecated. The *digestmod* parameter is now required. Pass it as a keyword argument to avoid awkwardness when you do not have an initial msg.

`hmac.digest(key, msg, digest)`

Return digest of *msg* for given secret *key* and *digest*. The function is equivalent to `HMAC(key, msg, digest).digest()`, but uses an optimized C or inline implementation, which is faster for messages that fit into memory. The parameters *key*, *msg*, and *digest* have the same

meaning as in `new()`.

CPython implementation detail, the optimized C implementation is only used when *digest* is a string and name of a digest algorithm, which is supported by OpenSSL.

*New in version 3.7.*

An HMAC object has the following methods:

`HMAC.update(msg)`

Update the hmac object with *msg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a)` ; `m.update(b)` is equivalent to `m.update(a + b)`.

*Changed in version 3.4:* Parameter *msg* can be of any type supported by `hashlib`.

`HMAC.digest()`

Return the digest of the bytes passed to the `update()` method so far. This bytes object will be the same length as the *digest\_size* of the digest given to the constructor. It may contain non-ASCII bytes, including NUL bytes.

### Warning

When comparing the output of `digest()` to an externally supplied digest during a verification routine, it is recommended to use the `compare_digest()` function instead of the `==` operator to reduce the vulnerability to timing attacks.

`HMAC.hexdigest()`

Like `digest()` except the digest is returned as a string twice the length containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

## Warning

When comparing the output of `hexdigest()` to an externally supplied digest during a verification routine, it is recommended to use the `compare_digest()` function instead of the `==` operator to reduce the vulnerability to timing attacks.

## HMAC.copy()

Return a copy (“clone”) of the hmac object. This can be used to efficiently compute the digests of strings that share a common initial substring.

A hash object has the following attributes:

### HMAC.digest\_size

The size of the resulting HMAC digest in bytes.

### HMAC.block\_size

The internal block size of the hash algorithm in bytes.

*New in version 3.4.*

### HMAC.name

The canonical name of this HMAC, always lowercase, e.g. `hmac-md5`.

*New in version 3.4.*

*Deprecated since version 3.9:* The undocumented attributes `HMAC.digest_cons`, `HMAC.inner`, and `HMAC.outer` are internal implementation details and will be removed in Python 3.10.

This module also provides the following helper function:

`hmac.compare_digest(a, b)`

Return `a == b`. This function uses an approach designed to prevent timing analysis by avoiding content-based short circuiting behaviour, making it appropriate for cryptography. *a* and *b* must both be of the same type: either `str` (ASCII only, as e.g. returned by `HMAC.hexdigest()`), or a `bytes-like object`.

### Note

If *a* and *b* are of different lengths, or if an error occurs, a timing attack could theoretically reveal information about the types and lengths of *a* and *b*—but not their values.

*New in version 3.3.*

*Changed in version 3.10:* The function uses OpenSSL's `CRYPTO_memcmp()` internally when available.

#### Module `hashlib`

The Python module providing secure hash functions.

# **secrets** — Generate secure random numbers for managing secrets

*New in version 3.6.*

**Source code:** [Lib/secrets.py](https://github.com/python/cpython/tree/3.11/Lib/secrets.py) [https://github.com/python/cpython/tree/3.11/Lib/secrets.py]

---

The **secrets** module is used for generating cryptographically strong random numbers suitable for managing data such as passwords, account authentication, security tokens, and related secrets.

In particular, **secrets** should be used in preference to the default pseudo-random number generator in the **random** module, which is designed for modelling and simulation, not security or cryptography.

**See also**

**PEP 506** [https://peps.python.org/pep-0506/]

## **Random numbers**

The **secrets** module provides access to the most secure source of randomness that your operating system provides.

*class* secrets.SystemRandom

A class for generating random numbers using the highest-quality sources provided by the operating system. See **random.SystemRandom** for additional details.

`secrets.choice(sequence)`

Return a randomly chosen element from a non-empty sequence.

`secrets.randbelow(n)`

Return a random int in the range  $[0, n)$ .

`secrets.randbits(k)`

Return an int with  $k$  random bits.

## Generating tokens

The `secrets` module provides functions for generating secure tokens, suitable for applications such as password resets, hard-to-guess URLs, and similar.

`secrets.token_bytes([nbytes=None])`

Return a random byte string containing *nbytes* number of bytes. If *nbytes* is `None` or not supplied, a reasonable default is used.

```
>>> token_bytes(16)
b'\xebr\x17D*t\xae\xd4\xe3S\xb6\xe2\xebP1\x8b'
```

`secrets.token_hex([nbytes=None])`

Return a random text string, in hexadecimal. The string has *nbytes* random bytes, each byte converted to two hex digits. If *nbytes* is `None` or not supplied, a reasonable default is used.

```
>>> token_hex(16)
'f9bf78b9a18ce6d46a0cd2b0b86df9da'
```

`secrets.token_urlsafe([nbytes=None])`

Return a random URL-safe text string, containing *nbytes* random bytes. The text is Base64 encoded, so on average each byte results in approximately 1.3 characters. If *nbytes* is `None`

or not supplied, a reasonable default is used.

```
>>> token_urlsafes(16)
'Drmhze6EPcv0fN_81Bj-nA'
```

## How many bytes should tokens use?

To be secure against [brute-force attacks](https://en.wikipedia.org/wiki/Brute-force_attack) [https://en.wikipedia.org/wiki/Brute-force\_attack], tokens need to have sufficient randomness. Unfortunately, what is considered sufficient will necessarily increase as computers get more powerful and able to make more guesses in a shorter period. As of 2015, it is believed that 32 bytes (256 bits) of randomness is sufficient for the typical use-case expected for the [secrets](#) module.

For those who want to manage their own token length, you can explicitly specify how much randomness is used for tokens by giving an [int](#) argument to the various `token_*` functions. That argument is taken as the number of bytes of randomness to use.

Otherwise, if no argument is provided, or if the argument is `None`, the `token_*` functions will use a reasonable default instead.

### Note

That default is subject to change at any time, including during maintenance releases.

## Other functions

`secrets.compare_digest(a, b)`

Return `True` if strings or [bytes-like objects](#) `a` and `b` are equal, otherwise `False`, using a “constant-time compare” to reduce the risk of [timing attacks](https://codahale.com/a-lesson-in-timing-attacks/) [https://codahale.com/a-lesson-in-timing-attacks/]. See [hmac.compare\\_digest\(\)](#) for additional details.

## Recipes and best practices

This section shows recipes and best practices for using `secrets` to manage a basic level of security.

Generate an eight-character alphanumeric password:

```
import string
import secrets
alphabet = string.ascii_letters + string.digits
password = ''.join(secrets.choice(alphabet) for i in range(8))
```

### Note

Applications should not [store passwords in a recoverable format](https://cwe.mitre.org/data/definitions/257.html) [https://cwe.mitre.org/data/definitions/257.html], whether plain text or encrypted. They should be salted and hashed using a cryptographically strong one-way (irreversible) hash function.

Generate a ten-character alphanumeric password with at least one lowercase character, at least one uppercase character, and at least three digits:

```
import string
import secrets
alphabet = string.ascii_letters + string.digits
while True:
    password = ''.join(secrets.choice(alphabet) for i in range(10))
    if (any(c.islower() for c in password)
        and any(c.isupper() for c in password)
        and sum(c.isdigit() for c in password) >= 3):
        break
```

Generate an [XKCD-style passphrase](https://xkcd.com/936/) [https://xkcd.com/936/]:

```
import secrets
# On standard Linux systems, use a convenient dictionary
# Other platforms may need to provide their own word-list
with open('/usr/share/dict/words') as f:
    words = [word.strip() for word in f]
password = ' '.join(secrets.choice(words) for i in range(4))
```

Generate a hard-to-guess temporary URL containing a security token suitable for password recovery applications:

```
import secrets
url = 'https://example.com/reset=' + secrets.token_urlsafe(32)
```

# Generic Operating System Services

The modules described in this chapter provide interfaces to operating system features that are available on (almost) all operating systems, such as files and a clock. The interfaces are generally modeled after the Unix or C interfaces, but they are available on most other systems as well. Here's an overview:

- **os** — Miscellaneous operating system interfaces
  - File Names, Command Line Arguments, and Environment Variables
  - Python UTF-8 Mode
  - Process Parameters
  - File Object Creation
  - File Descriptor Operations
    - Querying the size of a terminal
    - Inheritance of File Descriptors
  - Files and Directories
    - Linux extended attributes
  - Process Management
  - Interface to the scheduler
  - Miscellaneous System Information
  - Random numbers
- **io** — Core tools for working with streams
  - Overview
    - Text I/O
    - Binary I/O

- Raw I/O
- Text Encoding
  - Opt-in EncodingWarning
- High-level Module Interface
- Class hierarchy
  - I/O Base Classes
  - Raw File I/O
  - Buffered Streams
  - Text I/O
- Performance
  - Binary I/O
  - Text I/O
  - Multi-threading
  - Reentrancy
- **time** — Time access and conversions
  - Functions
  - Clock ID Constants
  - Timezone Constants
- **argparse** — Parser for command-line options, arguments and sub-commands

# os — Miscellaneous operating system interfaces

**Source code:** [Lib/os.py](https://github.com/python/cpython/tree/3.11/Lib/os.py) [https://github.com/python/cpython/tree/3.11/Lib/os.py]

---

This module provides a portable way of using operating system dependent functionality. If you just want to read or write a file see `open()`, if you want to manipulate paths, see the `os.path` module, and if you want to read all the lines in all the files on the command line see the `fileinput` module. For creating temporary files and directories see the `tempfile` module, and for high-level file and directory handling see the `shutil` module.

Notes on the availability of these functions:

- The design of all built-in operating system dependent modules of Python is such that as long as the same functionality is available, it uses the same interface; for example, the function `os.stat(path)` returns stat information about *path* in the same format (which happens to have originated with the POSIX interface).
- Extensions peculiar to a particular operating system are also available through the `os` module, but using them is of course a threat to portability.
- All functions accepting path or file names accept both bytes and string objects, and result in an object of the same type, if a path or file name is returned.
- On VxWorks, `os.popen`, `os.fork`, `os.execv` and `os.spawn*p*` are not supported.
- On WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`, large parts of the `os` module are not available or behave differently. API related to processes (e.g. `fork()`, `execve()`), signals (e.g. `kill()`, `wait()`), and resources (e.g. `nice()`) are not available. Others like

`getuid()` and `getpid()` are emulated or stubs.

## Note

All functions in this module raise `OSError` (or subclasses thereof) in the case of invalid or inaccessible file names and paths, or other arguments that have the correct type, but are not accepted by the operating system.

*exception* `os.error`

An alias for the built-in `OSError` exception.

`os.name`

The name of the operating system dependent module imported. The following names have currently been registered: 'posix', 'nt', 'java'.

## See also

`sys.platform` has a finer granularity. `os.uname()` gives system-dependent version information.

The `platform` module provides detailed checks for the system's identity.

# File Names, Command Line Arguments, and Environment Variables

In Python, file names, command line arguments, and environment variables are represented using the string type. On some systems, decoding these strings to and from bytes is necessary before passing them to the operating system. Python uses the `filesystem encoding and error handler` to perform this conversion (see `sys.getfilesystemencoding()`).

The `filesystem encoding and error handler` are configured at Python startup by the `PyConfig_Read()` function: see

`filesystem_encoding` and `filesystem_errors` members of `PyConfig`.

*Changed in version 3.1:* On some systems, conversion using the file system encoding may fail. In this case, Python uses the `surrogateescape encoding error handler`, which means that undecodable bytes are replaced by a Unicode character U+DCxx on decoding, and these are again translated to the original byte on encoding.

The `file system encoding` must guarantee to successfully decode all bytes below 128. If the file system encoding fails to provide this guarantee, API functions can raise `UnicodeError`.

See also the `locale encoding`.

## Python UTF-8 Mode

*New in version 3.7:* See [PEP 540](https://peps.python.org/pep-0540/) [https://peps.python.org/pep-0540/] for more details.

The Python UTF-8 Mode ignores the `locale encoding` and forces the usage of the UTF-8 encoding:

- Use UTF-8 as the `filesystem encoding`.
- `sys.getfilesystemencoding()` returns `'utf-8'`.
- `locale.getpreferredencoding()` returns `'utf-8'` (the `do_setlocale` argument has no effect).
- `sys.stdin`, `sys.stdout`, and `sys.stderr` all use UTF-8 as their text encoding, with the `surrogateescape error handler` being enabled for `sys.stdin` and `sys.stdout` (`sys.stderr` continues to use `backslashreplace` as it does in the default locale-aware mode)
- On Unix, `os.device_encoding()` returns `'utf-8'` rather than the device encoding.

Note that the standard stream settings in UTF-8 mode can be overridden by `PYTHONIOENCODING` (just as they can be in the default locale-aware mode).

As a consequence of the changes in those lower level APIs, other

higher level APIs also exhibit different default behaviours:

- Command line arguments, environment variables and filenames are decoded to text using the UTF-8 encoding.
- `os.fsdecode()` and `os.fsencode()` use the UTF-8 encoding.
- `open()`, `io.open()`, and `codecs.open()` use the UTF-8 encoding by default. However, they still use the strict error handler by default so that attempting to open a binary file in text mode is likely to raise an exception rather than producing nonsense data.

The [Python UTF-8 Mode](#) is enabled if the LC\_CTYPE locale is `C` or `POSIX` at Python startup (see the `PyConfig_Read()` function).

It can be enabled or disabled using the `-X utf8` command line option and the `PYTHONUTF8` environment variable.

If the `PYTHONUTF8` environment variable is not set at all, then the interpreter defaults to using the current locale settings, *unless* the current locale is identified as a legacy ASCII-based locale (as described for [PYTHONCOERCECLOCALE](#)), and locale coercion is either disabled or fails. In such legacy locales, the interpreter will default to enabling UTF-8 mode unless explicitly instructed not to do so.

The Python UTF-8 Mode can only be enabled at the Python startup. Its value can be read from `sys.flags.utf8_mode`.

See also the [UTF-8 mode on Windows](#) and the [filesystem encoding and error handler](#).

See also

[PEP 686](#) [<https://peps.python.org/pep-0686/>]

Python 3.15 will make [Python UTF-8 Mode](#) default.

## Process Parameters

These functions and data items provide information and operate on

the current process and user.

## `os.ctermid()`

Return the filename corresponding to the controlling terminal of the process.

**Availability:** Unix, not Emscripten, not WASI.

## `os.environ`

A **mapping** object where keys and values are strings that represent the process environment. For example, `environ['HOME']` is the pathname of your home directory (on some platforms), and is equivalent to `getenv("HOME")` in C.

This mapping is captured the first time the **os** module is imported, typically during Python startup as part of processing `site.py`. Changes to the environment made after this time are not reflected in **os.environ**, except for changes made by modifying **os.environ** directly.

This mapping may be used to modify the environment as well as query the environment. **putenv()** will be called automatically when the mapping is modified.

On Unix, keys and values use **sys.getfilesystemencoding()** and `'surrogateescape'` error handler. Use **environb** if you would like to use a different encoding.

On Windows, the keys are converted to uppercase. This also applies when getting, setting, or deleting an item. For example, `environ['monty'] = 'python'` maps the key `'MONTY'` to the value `'python'`.

### Note

Calling **putenv()** directly does not change **os.environ**, so it's better to modify **os.environ**.

## Note

On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

You can delete items in this mapping to unset environment variables. `unsetenv()` will be called automatically when an item is deleted from `os.environ`, and when one of the `pop()` or `clear()` methods is called.

*Changed in version 3.9:* Updated to support [PEP 584](https://peps.python.org/pep-0584/) [https://peps.python.org/pep-0584/]’s merge (`|`) and update (`|=`) operators.

## `os.environb`

Bytes version of `environ`: a mapping object where both keys and values are `bytes` objects representing the process environment. `environ` and `environb` are synchronized (modifying `environb` updates `environ`, and vice versa).

`environb` is only available if `supports_bytes_environ` is `True`.

*New in version 3.2.*

*Changed in version 3.9:* Updated to support [PEP 584](https://peps.python.org/pep-0584/) [https://peps.python.org/pep-0584/]’s merge (`|`) and update (`|=`) operators.

## `os.chdir(path)`

## `os.fchdir(fd)`

## `os.getcwd()`

These functions are described in [Files and Directories](#).

## `os.fsencode(filename)`

Encode `path-like filename` to the `filesystem encoding and error handler`; return `bytes` unchanged.

**fsdecode()** is the reverse function.

*New in version 3.2.*

*Changed in version 3.6:* Support added to accept objects implementing the **os.PathLike** interface.

**os.fsdecode(filename)**

Decode the **path-like filename** from the **filesystem encoding and error handler**; return **str** unchanged.

**fsencode()** is the reverse function.

*New in version 3.2.*

*Changed in version 3.6:* Support added to accept objects implementing the **os.PathLike** interface.

**os.fspath(path)**

Return the file system representation of the path.

If **str** or **bytes** is passed in, it is returned unchanged. Otherwise **\_\_fspath\_\_()** is called and its value is returned as long as it is a **str** or **bytes** object. In all other cases, **TypeError** is raised.

*New in version 3.6.*

**class os.PathLike**

An **abstract base class** for objects representing a file system path, e.g. **pathlib.PurePath**.

*New in version 3.6.*

**abstractmethod \_\_fspath\_\_()**

Return the file system path representation of the object.

The method should only return a **str** or **bytes** object, with the preference being for **str**.

`os.getenv(key, default=None)`

Return the value of the environment variable *key* as a string if it exists, or *default* if it doesn't. *key* is a string. Note that since `getenv()` uses `os.environ`, the mapping of `getenv()` is similarly also captured on import, and the function may not reflect future environment changes.

On Unix, keys and values are decoded with `sys.getfilesystemencoding()` and 'surrogateescape' error handler. Use `os.getenvb()` if you would like to use a different encoding.

**Availability:** Unix, Windows.

`os.getenvb(key, default=None)`

Return the value of the environment variable *key* as bytes if it exists, or *default* if it doesn't. *key* must be bytes. Note that since `getenvb()` uses `os.environb`, the mapping of `getenvb()` is similarly also captured on import, and the function may not reflect future environment changes.

`getenvb()` is only available if `supports_bytes_environ` is `True`.

**Availability:** Unix.

*New in version 3.2.*

`os.get_exec_path(env=None)`

Returns the list of directories that will be searched for a named executable, similar to a shell, when launching a process. *env*, when specified, should be an environment variable dictionary to lookup the PATH in. By default, when *env* is `None`, `environ` is used.

*New in version 3.2.*

`os.getegid()`

Return the effective group id of the current process. This

corresponds to the “set id” bit on the file being executed in the current process.

**Availability:** Unix, not Emscripten, not WASI.

`os.geteuid()`

Return the current process’s effective user id.

**Availability:** Unix, not Emscripten, not WASI.

`os.getgid()`

Return the real group id of the current process.

**Availability:** Unix.

The function is a stub on Emscripten and WASI, see [WebAssembly platforms](#) for more information.

`os.getgrouplist(user, group, /)`

Return list of group ids that *user* belongs to. If *group* is not in the list, it is included; typically, *group* is specified as the group ID field from the password record for *user*, because that group ID will otherwise be potentially omitted.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3.*

`os.getgroups()`

Return list of supplemental group ids associated with the current process.

**Availability:** Unix, not Emscripten, not WASI.

### **Note**

On macOS, `getgroups()` behavior differs somewhat from other Unix platforms. If the Python interpreter was built with a deployment target of `10.5` or earlier,

`getgroups()` returns the list of effective group ids associated with the current user process; this list is limited to a system-defined number of entries, typically 16, and may be modified by calls to `setgroups()` if suitably privileged. If built with a deployment target greater than 10.5, `getgroups()` returns the current group access list for the user associated with the effective user id of the process; the group access list may change over the lifetime of the process, it is not affected by calls to `setgroups()`, and its length is not limited to 16. The deployment target value, `MACOSX_DEPLOYMENT_TARGET`, can be obtained with `sysconfig.get_config_var()`.

## `os.getlogin()`

Return the name of the user logged in on the controlling terminal of the process. For most purposes, it is more useful to use `getpass.getuser()` since the latter checks the environment variables `LOGNAME` or `USERNAME` to find out who the user is, and falls back to `pwd.getpwuid(os.getuid())[0]` to get the login name of the current real user id.

**Availability:** Unix, Windows, not Emscripten, not WASI.

## `os.getpgid(pid)`

Return the process group id of the process with process id *pid*. If *pid* is 0, the process group id of the current process is returned.

**Availability:** Unix, not Emscripten, not WASI.

## `os.getpgrp()`

Return the id of the current process group.

**Availability:** Unix, not Emscripten, not WASI.

## `os.getpid()`

Return the current process id.

The function is a stub on Emscripten and WASI, see [WebAssembly platforms](#) for more information.

## `os.getppid()`

Return the parent's process id. When the parent process has exited, on Unix the id returned is the one of the init process (1), on Windows it is still the same id, which may be already reused by another process.

**Availability:** Unix, Windows, not Emscripten, not WASI.

*Changed in version 3.2:* Added support for Windows.

## `os.getpriority(which, who)`

Get program scheduling priority. The value *which* is one of [PRIO\\_PROCESS](#), [PRIO\\_PGRP](#), or [PRIO\\_USER](#), and *who* is interpreted relative to *which* (a process identifier for [PRIO\\_PROCESS](#), process group identifier for [PRIO\\_PGRP](#), and a user ID for [PRIO\\_USER](#)). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3.*

`os.PRIO_PROCESS`

`os.PRIO_PGRP`

`os.PRIO_USER`

Parameters for the [getpriority\(\)](#) and [setpriority\(\)](#) functions.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3.*

## `os.getresuid()`

Return a tuple (ruid, euid, suid) denoting the current process's real, effective, and saved user ids.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.2.*

`os.getresgid()`

Return a tuple (rgid, egid, sgid) denoting the current process's real, effective, and saved group ids.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.2.*

`os.getuid()`

Return the current process's real user id.

**Availability:** Unix.

The function is a stub on Emscripten and WASI, see [WebAssembly platforms](#) for more information.

`os.initgroups(username, gid, /)`

Call the system `initgroups()` to initialize the group access list with all of the groups of which the specified username is a member, plus the specified group id.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.2.*

`os.putenv(key, value, /)`

Set the environment variable named *key* to the string *value*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

Assignments to items in `os.environ` are automatically translated into corresponding calls to `putenv()`; however,

calls to `putenv()` don't update `os.environ`, so it is actually preferable to assign to items of `os.environ`. This also applies to `getenv()` and `getenvb()`, which respectively use `os.environ` and `os.environb` in their implementations.

### Note

On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

Raises an [auditing event](#) `os.putenv` with arguments `key`, `value`.

*Changed in version 3.9:* The function is now always available.

`os.setegid(egid, /)`

Set the current process's effective group id.

[Availability](#): Unix, not Emscripten, not WASI.

`os.seteuid(euid, /)`

Set the current process's effective user id.

[Availability](#): Unix, not Emscripten, not WASI.

`os.setgid(gid, /)`

Set the current process' group id.

[Availability](#): Unix, not Emscripten, not WASI.

`os.setgroups(groups, /)`

Set the list of supplemental group ids associated with the current process to *groups*. *groups* must be a sequence, and each element must be an integer identifying a group. This operation is typically available only to the superuser.

**Availability:** Unix, not Emscripten, not WASI.

### Note

On macOS, the length of *groups* may not exceed the system-defined maximum number of effective group ids, typically 16. See the documentation for [getgroups\(\)](#) for cases where it may not return the same group list set by calling `setgroups()`.

`os.setpgrp()`

Call the system call **setpgrp()** or `setpgrp(0, 0)` depending on which version is implemented (if any). See the Unix manual for the semantics.

**Availability:** Unix, not Emscripten, not WASI.

`os.setpgid(pid, pgrp, /)`

Call the system call **setpgid()** to set the process group id of the process with id *pid* to the process group with id *pgrp*. See the Unix manual for the semantics.

**Availability:** Unix, not Emscripten, not WASI.

`os.setpriority(which, who, priority)`

Set program scheduling priority. The value *which* is one of [PRIO\\_PROCESS](#), [PRIO\\_PGRP](#), or [PRIO\\_USER](#), and *who* is interpreted relative to *which* (a process identifier for [PRIO\\_PROCESS](#), process group identifier for [PRIO\\_PGRP](#), and a user ID for [PRIO\\_USER](#)). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process. *priority* is a value in the range -20 to 19. The default priority is 0; lower priorities cause more favorable scheduling.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3.*

`os.setregid(rgid, egid, /)`

Set the current process's real and effective group ids.

**Availability:** Unix, not Emscripten, not WASI.

`os.setresgid(rgid, egid, sgid, /)`

Set the current process's real, effective, and saved group ids.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.2.*

`os.setresuid(ruid, euid, suid, /)`

Set the current process's real, effective, and saved user ids.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.2.*

`os.setreuid(ruid, euid, /)`

Set the current process's real and effective user ids.

**Availability:** Unix, not Emscripten, not WASI.

`os.getsid(pid, /)`

Call the system call `getsid()`. See the Unix manual for the semantics.

**Availability:** Unix, not Emscripten, not WASI.

`os.setsid()`

Call the system call `setsid()`. See the Unix manual for the semantics.

**Availability:** Unix, not Emscripten, not WASI.

`os.setuid(uid, /)`

Set the current process's user id.

**Availability:** Unix, not Emscripten, not WASI.

`os.strerror(code, /)`

Return the error message corresponding to the error code in *code*. On platforms where `strerror()` returns `NULL` when given an unknown error number, **ValueError** is raised.

`os.supports_bytes_environ`

`True` if the native OS type of the environment is bytes (eg. `False` on Windows).

*New in version 3.2.*

`os.umask(mask, /)`

Set the current numeric umask and return the previous umask.

The function is a stub on Emscripten and WASI, see [WebAssembly platforms](#) for more information.

`os.uname()`

Returns information identifying the current operating system. The return value is an object with five attributes:

- **sysname** - operating system name
- **nodename** - name of machine on network (implementation-defined)
- **release** - operating system release
- **version** - operating system version
- **machine** - hardware identifier

For backwards compatibility, this object is also iterable, behaving like a five-tuple containing **sysname**, **nodename**, **release**, **version**, and **machine** in that order.

Some systems truncate **nodename** to 8 characters or to the leading component; a better way to get the hostname is

`socket.gethostname()` or even  
`socket.gethostbyaddr(socket.gethostname())`.

**Availability:** Unix.

*Changed in version 3.3:* Return type changed from a tuple to a tuple-like object with named attributes.

`os.unsetenv(key, /)`

Unset (delete) the environment variable named *key*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

Deletion of items in `os.environ` is automatically translated into a corresponding call to `unsetenv()`; however, calls to `unsetenv()` don't update `os.environ`, so it is actually preferable to delete items of `os.environ`.

Raises an **auditing event** `os.unsetenv` with argument *key*.

*Changed in version 3.9:* The function is now always available and is also available on Windows.

## File Object Creation

These functions create new **file objects**. (See also `open()` for opening file descriptors.)

`os.fdopen(fd, *args, **kwargs)`

Return an open file object connected to the file descriptor *fd*. This is an alias of the `open()` built-in function and accepts the same arguments. The only difference is that the first argument of `fdopen()` must always be an integer.

## File Descriptor Operations

These functions operate on I/O streams referenced using file descriptors.

File descriptors are small integers corresponding to a file that has been opened by the current process. For example, standard input is usually file descriptor 0, standard output is 1, and standard error is 2. Further files opened by a process will then be assigned 3, 4, 5, and so forth. The name “file descriptor” is slightly deceptive; on Unix platforms, sockets and pipes are also referenced by file descriptors.

The `fileno()` method can be used to obtain the file descriptor associated with a `file object` when required. Note that using the file descriptor directly will bypass the file object methods, ignoring aspects such as internal buffering of data.

`os.close(fd)`

Close file descriptor *fd*.

### Note

This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To close a “file object” returned by the built-in function `open()` or by `popen()` or `fdopen()`, use its `close()` method.

`os.closerange(fd_low, fd_high, /)`

Close all file descriptors from *fd\_low* (inclusive) to *fd\_high* (exclusive), ignoring errors. Equivalent to (but much faster than):

```
for fd in range(fd_low, fd_high):
    try:
        os.close(fd)
    except OSError:
        pass
```

`os.copy_file_range(src, dst, count, offset_src=None, offset_dst=None)`

Copy *count* bytes from file descriptor *src*, starting from offset *offset\_src*, to file descriptor *dst*, starting from offset *offset\_dst*. If

`offset_src` is `None`, then `src` is read from the current position; respectively for `offset_dst`. The files pointed by `src` and `dst` must reside in the same filesystem, otherwise an `OSError` is raised with `errno` set to `errno.EXDEV`.

This copy is done without the additional cost of transferring data from the kernel to user space and then back into the kernel. Additionally, some filesystems could implement extra optimizations. The copy is done as if both files are opened as binary.

The return value is the amount of bytes copied. This could be less than the amount requested.

**Availability:** Linux  $\geq 4.5$  with glibc  $\geq 2.27$ .

*New in version 3.8.*

`os.device_encoding(fd)`

Return a string describing the encoding of the device associated with `fd` if it is connected to a terminal; else return `None`.

On Unix, if the [Python UTF-8 Mode](#) is enabled, return `'UTF-8'` rather than the device encoding.

*Changed in version 3.10:* On Unix, the function now implements the Python UTF-8 Mode.

`os.dup(fd, /)`

Return a duplicate of file descriptor `fd`. The new file descriptor is [non-inheritable](#).

On Windows, when duplicating a standard stream (0: stdin, 1: stdout, 2: stderr), the new file descriptor is [inheritable](#).

**Availability:** not WASI.

*Changed in version 3.4:* The new file descriptor is now non-inheritable.

`os.dup2(fd, fd2, inheritable = True)`

Duplicate file descriptor *fd* to *fd2*, closing the latter first if necessary. Return *fd2*. The new file descriptor is [inheritable](#) by default or non-inheritable if *inheritable* is `False`.

[Availability](#): not WASI.

*Changed in version 3.4*: Add the optional *inheritable* parameter.

*Changed in version 3.7*: Return *fd2* on success. Previously, `None` was always returned.

`os.fchmod(fd, mode)`

Change the mode of the file given by *fd* to the numeric *mode*. See the docs for [chmod\(\)](#) for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(fd, mode)`.

Raises an [auditing event](#) `os.chmod` with arguments `path`, `mode`, `dir_fd`.

[Availability](#): Unix.

The function is limited on Emscripten and WASI, see [WebAssembly platforms](#) for more information.

`os.fchown(fd, uid, gid)`

Change the owner and group id of the file given by *fd* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to `-1`. See [chown\(\)](#). As of Python 3.3, this is equivalent to `os.chown(fd, uid, gid)`.

Raises an [auditing event](#) `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

[Availability](#): Unix.

The function is limited on Emscripten and WASI, see [WebAssembly platforms](#) for more information.

`os.fdatasync(fd)`

Force write of file with filedescriptor *fd* to disk. Does not force update of metadata.

**Availability:** Unix.

### Note

This function is not available on MacOS.

`os.fpathconf(fd, name, /)`

Return system configuration information relevant to an open file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, **ValueError** is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an **OSError** is raised with `errno.EINVAL` for the error number.

As of Python 3.3, this is equivalent to `os.pathconf(fd, name)`.

**Availability:** Unix.

`os.fstat(fd)`

Get the status of the file descriptor *fd*. Return a **stat\_result** object.

As of Python 3.3, this is equivalent to `os.stat(fd)`.

**See also**

The `stat()` function.

`os.fstatvfs(fd, /)`

Return information about the filesystem containing the file associated with file descriptor `fd`, like `statvfs()`. As of Python 3.3, this is equivalent to `os.statvfs(fd)`.

**Availability:** Unix.

`os.fsync(fd)`

Force write of file with filedescriptor `fd` to disk. On Unix, this calls the native `fsync()` function; on Windows, the `MS _commit()` function.

If you're starting with a buffered Python [file object](#) `f`, first do `f.flush()`, and then do `os.fsync(f.fileno())`, to ensure that all internal buffers associated with `f` are written to disk.

**Availability:** Unix, Windows.

`os.ftruncate(fd, length, /)`

Truncate the file corresponding to file descriptor `fd`, so that it is at most `length` bytes in size. As of Python 3.3, this is equivalent to `os.truncate(fd, length)`.

Raises an [auditing event](#) `os.truncate` with arguments `fd`, `length`.

**Availability:** Unix, Windows.

*Changed in version 3.5:* Added support for Windows

`os.get_blocking(fd, /)`

Get the blocking mode of the file descriptor: `False` if the `O_NONBLOCK` flag is set, `True` if the flag is cleared.

See also `set_blocking()` and

`socket.socket.setblocking()`.

**Availability:** Unix.

The function is limited on Emscripten and WASI, see [WebAssembly platforms](#) for more information.

*New in version 3.5.*

`os.isatty(fd, /)`

Return `True` if the file descriptor `fd` is open and connected to a tty(-like) device, else `False`.

`os.lockf(fd, cmd, len, /)`

Apply, test or remove a POSIX lock on an open file descriptor. `fd` is an open file descriptor. `cmd` specifies the command to use - one of `F_LOCK`, `F_TLOCK`, `F_ULOCK` or `F_TEST`. `len` specifies the section of the file to lock.

Raises an [auditing event](#) `os.lockf` with arguments `fd`, `cmd`, `len`.

**Availability:** Unix.

*New in version 3.3.*

`os.F_LOCK`

`os.F_TLOCK`

`os.F_ULOCK`

`os.F_TEST`

Flags that specify what action `lockf()` will take.

**Availability:** Unix.

*New in version 3.3.*

`os.login_tty(fd, /)`

Prepare the tty of which `fd` is a file descriptor for a new login session. Make the calling process a session leader; make the

tty the controlling tty, the stdin, the stdout, and the stderr of the calling process; close fd.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.11.*

`os.lseek(fd, pos, how, /)`

Set the current position of file descriptor *fd* to position *pos*, modified by *how*: **SEEK\_SET** or 0 to set the position relative to the beginning of the file; **SEEK\_CUR** or 1 to set it relative to the current position; **SEEK\_END** or 2 to set it relative to the end of the file. Return the new cursor position in bytes, starting from the beginning.

`os.SEEK_SET`

`os.SEEK_CUR`

`os.SEEK_END`

Parameters to the **lseek()** function. Their values are 0, 1, and 2, respectively.

*New in version 3.3:* Some operating systems could support additional values, like `os.SEEK_HOLE` or `os.SEEK_DATA`.

`os.open(path, flags, mode=0o777, *, dir_fd=None)`

Open the file *path* and set various flags according to *flags* and possibly its mode according to *mode*. When computing *mode*, the current umask value is first masked out. Return the file descriptor for the newly opened file. The new file descriptor is **non-inheritable**.

For a description of the flag and mode values, see the C runtime documentation; flag constants (like **O\_RDONLY** and **O\_WRONLY**) are defined in the `os` module. In particular, on Windows adding **O\_BINARY** is needed to open files in binary mode.

This function can support **paths relative to directory descriptors** with the *dir\_fd* parameter.

Raises an [auditing event](#) `open` with arguments `path`, `mode`, `flags`.

*Changed in version 3.4:* The new file descriptor is now non-inheritable.

### Note

This function is intended for low-level I/O. For normal usage, use the built-in function `open()`, which returns a [file object](#) with `read()` and `write()` methods (and many more). To wrap a file descriptor in a file object, use `fdopen()`.

*New in version 3.3:* The `dir_fd` argument.

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an [InterruptedError](#) exception (see [PEP 475](#) [<https://peps.python.org/pep-0475/>] for the rationale).

*Changed in version 3.6:* Accepts a [path-like object](#).

The following constants are options for the `flags` parameter to the `open()` function. They can be combined using the bitwise OR operator `|`. Some of them are not available on all platforms. For descriptions of their availability and use, consult the [`open\(2\)` manual page](#) on Unix or [the MSDN](#) [<https://msdn.microsoft.com/en-us/library/z0kc8e3z.aspx>] on Windows.

`os.O_RDONLY`  
`os.O_WRONLY`  
`os.O_RDWR`  
`os.O_APPEND`  
`os.O_CREAT`  
`os.O_EXCL`  
`os.O_TRUNC`

The above constants are available on Unix and Windows.

os.O\_DSYNC  
os.O\_RSYNC  
os.O\_SYNC  
os.O\_NDELAY  
os.O\_NONBLOCK  
os.O\_NOCTTY  
os.O\_CLOEXEC

The above constants are only available on Unix.

*Changed in version 3.3:* Add [O\\_CLOEXEC](#) constant.

os.O\_BINARY  
os.O\_NOINHERIT  
os.O\_SHORT\_LIVED  
os.O\_TEMPORARY  
os.O\_RANDOM  
os.O\_SEQUENTIAL  
os.O\_TEXT

The above constants are only available on Windows.

os.O\_EVTONLY  
os.O\_FSYNC  
os.O\_SYMLINK  
os.O\_NOFOLLOW\_ANY

The above constants are only available on macOS.

*Changed in version 3.10:* Add [O\\_EVTONLY](#), [O\\_FSYNC](#),  
[O\\_SYMLINK](#) and [O\\_NOFOLLOW\\_ANY](#) constants.

os.O\_ASYNC  
os.O\_DIRECT  
os.O\_DIRECTORY  
os.O\_NOFOLLOW  
os.O\_NOATIME  
os.O\_PATH  
os.O\_TMPFILE  
os.O\_SHLOCK  
os.O\_EXLOCK

The above constants are extensions and not present if they are

not defined by the C library.

*Changed in version 3.4:* Add `O_PATH` on systems that support it. Add `O_TMPFILE`, only available on Linux Kernel 3.11 or newer.

## `os.openpty()`

Open a new pseudo-terminal pair. Return a pair of file descriptors (`master`, `slave`) for the pty and the tty, respectively. The new file descriptors are [non-inheritable](#). For a (slightly) more portable approach, use the [pty](#) module.

**Availability:** Unix, not Emscripten, not WASI.

*Changed in version 3.4:* The new file descriptors are now non-inheritable.

## `os.pipe()`

Create a pipe. Return a pair of file descriptors (`r`, `w`) usable for reading and writing, respectively. The new file descriptor is [non-inheritable](#).

**Availability:** Unix, Windows.

*Changed in version 3.4:* The new file descriptors are now non-inheritable.

## `os.pipe2(flags, /)`

Create a pipe with *flags* set atomically. *flags* can be constructed by ORing together one or more of these values: `O_NONBLOCK`, `O_CLOEXEC`. Return a pair of file descriptors (`r`, `w`) usable for reading and writing, respectively.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3.*

## `os.posix_fallocate(fd, offset, len, /)`

Ensures that enough disk space is allocated for the file

specified by *fd* starting from *offset* and continuing for *len* bytes.

**Availability:** Unix, not Emscripten.

*New in version 3.3.*

`os.posix_fadvise(fd, offset, len, advice, /)`

Announces an intention to access data in a specific pattern thus allowing the kernel to make optimizations. The *advice* applies to the region of the file specified by *fd* starting at *offset* and continuing for *len* bytes. *advice* is one of `POSIX_FADV_NORMAL`, `POSIX_FADV_SEQUENTIAL`, `POSIX_FADV_RANDOM`, `POSIX_FADV_NOREUSE`, `POSIX_FADV_WILLNEED` or `POSIX_FADV_DONTNEED`.

**Availability:** Unix.

*New in version 3.3.*

`os.POSIX_FADV_NORMAL`  
`os.POSIX_FADV_SEQUENTIAL`  
`os.POSIX_FADV_RANDOM`  
`os.POSIX_FADV_NOREUSE`  
`os.POSIX_FADV_WILLNEED`  
`os.POSIX_FADV_DONTNEED`

Flags that can be used in *advice* in `posix_fadvise()` that specify the access pattern that is likely to be used.

**Availability:** Unix.

*New in version 3.3.*

`os.pread(fd, n, offset, /)`

Read at most *n* bytes from file descriptor *fd* at a position of *offset*, leaving the file offset unchanged.

Return a bytestring containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

**Availability:** Unix.

*New in version 3.3.*

`os.preadv(fd, buffers, offset, flags=0, /)`

Read from a file descriptor *fd* at a position of *offset* into mutable **bytes-like objects** *buffers*, leaving the file offset unchanged. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

The flags argument contains a bitwise OR of zero or more of the following flags:

- **RWF\_HIPRI**
- **RWF\_NOWAIT**

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (**sysconf()** value 'SC\_IOV\_MAX') on the number of buffers that can be used.

Combine the functionality of **os.readv()** and **os.pread()**.

**Availability:** Linux  $\geq$  2.6.30, FreeBSD  $\geq$  6.0, OpenBSD  $\geq$  2.7, AIX  $\geq$  7.1.

Using flags requires Linux  $\geq$  4.6.

*New in version 3.7.*

`os.RWF_NOWAIT`

Do not wait for data which is not immediately available. If this flag is specified, the system call will return instantly if it would have to read data from the backing storage or wait for a lock.

If some data was successfully read, it will return the number of bytes read. If no bytes were read, it will return `-1` and set

errno to `errno.EAGAIN`.

**Availability:** Linux  $\geq$  4.14.

*New in version 3.7.*

## os.RWF\_HIPRI

High priority read/write. Allows block-based filesystems to use polling of the device, which provides lower latency, but may use additional resources.

Currently, on Linux, this feature is usable only on a file descriptor opened using the `O_DIRECT` flag.

**Availability:** Linux  $\geq$  4.6.

*New in version 3.7.*

## os.pwrite(*fd*, *str*, *offset*, /)

Write the bytestring in *str* to file descriptor *fd* at position of *offset*, leaving the file offset unchanged.

Return the number of bytes actually written.

**Availability:** Unix.

*New in version 3.3.*

## os.pwritev(*fd*, *buffers*, *offset*, *flags*=0, /)

Write the *buffers* contents to file descriptor *fd* at a offset *offset*, leaving the file offset unchanged. *buffers* must be a sequence of **bytes-like objects**. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

The *flags* argument contains a bitwise OR of zero or more of the following flags:

- `RWF_DSYNC`
- `RWF_SYNC`

- **RWF\_APPEND**

Return the total number of bytes actually written.

The operating system may set a limit (**sysconf()** value 'SC\_IOV\_MAX') on the number of buffers that can be used.

Combine the functionality of **os.writev()** and **os.pwrite()**.

**Availability:** Linux  $\geq$  2.6.30, FreeBSD  $\geq$  6.0, OpenBSD  $\geq$  2.7, AIX  $\geq$  7.1.

Using flags requires Linux  $\geq$  4.6.

*New in version 3.7.*

#### os.RWF\_DSYNC

Provide a per-write equivalent of the **O\_DSYNC os.open()** flag. This flag effect applies only to the data range written by the system call.

**Availability:** Linux  $\geq$  4.7.

*New in version 3.7.*

#### os.RWF\_SYNC

Provide a per-write equivalent of the **O\_SYNC os.open()** flag. This flag effect applies only to the data range written by the system call.

**Availability:** Linux  $\geq$  4.7.

*New in version 3.7.*

#### os.RWF\_APPEND

Provide a per-write equivalent of the **O\_APPEND os.open()** flag. This flag is meaningful only for **os.pwritev()**, and its effect applies only to the data range written by the system call. The *offset* argument does not affect the write operation; the data is always appended to the end of

the file. However, if the *offset* argument is `-1`, the current file *offset* is updated.

**Availability:** Linux  $\geq$  4.16.

*New in version 3.10.*

`os.read(fd, n, /)`

Read at most *n* bytes from file descriptor *fd*.

Return a `bytes` object containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty `bytes` object is returned.

### Note

This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To read a “file object” returned by the built-in function `open()` or by `popen()` or `fdopen()`, or `sys.stdin`, use its `read()` or `readline()` methods.

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an

`InterruptedError` exception (see [PEP 475](https://peps.python.org/pep-0475/) [https://peps.python.org/pep-0475/] for the rationale).

`os.sendfile(out_fd, in_fd, offset, count)`

`os.sendfile(out_fd, in_fd, offset, count, headers=(), trailers=(), flags=0)`

Copy *count* bytes from file descriptor *in\_fd* to file descriptor *out\_fd* starting at *offset*. Return the number of bytes sent. When EOF is reached return `0`.

The first function notation is supported by all platforms that define `sendfile()`.

On Linux, if *offset* is given as `None`, the bytes are read from

the current position of *in\_fd* and the position of *in\_fd* is updated.

The second case may be used on macOS and FreeBSD where *headers* and *trailers* are arbitrary sequences of buffers that are written before and after the data from *in\_fd* is written. It returns the same as the first case.

On macOS and FreeBSD, a value of 0 for *count* specifies to send until the end of *in\_fd* is reached.

All platforms support sockets as *out\_fd* file descriptor, and some platforms allow other types (e.g. regular file, pipe) as well.

Cross-platform applications should not use *headers*, *trailers* and *flags* arguments.

**Availability:** Unix, not Emscripten, not WASI.

### Note

For a higher-level wrapper of `sendfile()`, see `socket.socket.sendfile()`.

*New in version 3.3.*

*Changed in version 3.9:* Parameters *out* and *in* was renamed to *out\_fd* and *in\_fd*.

`os.set_blocking(fd, blocking, /)`

Set the blocking mode of the specified file descriptor. Set the `O_NONBLOCK` flag if blocking is `False`, clear the flag otherwise.

See also `get_blocking()` and `socket.socket.setblocking()`.

**Availability:** Unix.

The function is limited on Emscripten and WASI, see

[WebAssembly platforms](#) for more information.

*New in version 3.5.*

os.SF\_NODISKIO

os.SF\_MNOWAIT

os.SF\_SYNC

Parameters to the [sendfile\(\)](#) function, if the implementation supports them.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3.*

os.SF\_NOCACHE

Parameter to the [sendfile\(\)](#) function, if the implementation supports it. The data won't be cached in the virtual memory and will be freed afterwards.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.11.*

os.splice(*src*, *dst*, *count*, *offset\_src*=None, *offset\_dst*=None)

Transfer *count* bytes from file descriptor *src*, starting from offset *offset\_src*, to file descriptor *dst*, starting from offset *offset\_dst*. At least one of the file descriptors must refer to a pipe. If *offset\_src* is None, then *src* is read from the current position; respectively for *offset\_dst*. The offset associated to the file descriptor that refers to a pipe must be None. The files pointed by *src* and *dst* must reside in the same filesystem, otherwise an **OSError** is raised with **errno** set to **errno.EXDEV**.

This copy is done without the additional cost of transferring data from the kernel to user space and then back into the kernel. Additionally, some filesystems could implement extra optimizations. The copy is done as if both files are opened as binary.

Upon successful completion, returns the number of bytes spliced to or from the pipe. A return value of 0 means end of input. If *src* refers to a pipe, then this means that there was no data to transfer, and it would not make sense to block because there are no writers connected to the write end of the pipe.

**Availability:** Linux  $\geq$  2.6.17 with glibc  $\geq$  2.5

*New in version 3.10.*

os.SPLICE\_F\_MOVE  
os.SPLICE\_F\_NONBLOCK  
os.SPLICE\_F\_MORE

*New in version 3.10.*

os.readv(*fd*, *buffers*, /)

Read from a file descriptor *fd* into a number of mutable **bytes-like objects** *buffers*. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (**sysconf()** value 'SC\_IOV\_MAX') on the number of buffers that can be used.

**Availability:** Unix.

*New in version 3.3.*

os.tcgetpgrp(*fd*, /)

Return the process group associated with the terminal given by *fd* (an open file descriptor as returned by **os.open()**).

**Availability:** Unix, not WASI.

os.tcsetpgrp(*fd*, *pg*, /)

Set the process group associated with the terminal given by *fd* (an open file descriptor as returned by `os.open()`) to *pg*.

**Availability:** Unix, not WASI.

`os.ttyname(fd, /)`

Return a string which specifies the terminal device associated with file descriptor *fd*. If *fd* is not associated with a terminal device, an exception is raised.

**Availability:** Unix.

`os.write(fd, str, /)`

Write the bytestring in *str* to file descriptor *fd*.

Return the number of bytes actually written.

### Note

This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To write a “file object” returned by the built-in function `open()` or by `popen()` or `fdopen()`, or `sys.stdout` or `sys.stderr`, use its `write()` method.

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](https://peps.python.org/pep-0475/) [https://peps.python.org/pep-0475/] for the rationale).

`os.writev(fd, buffers, /)`

Write the contents of *buffers* to file descriptor *fd*. *buffers* must be a sequence of [bytes-like objects](#). Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

Returns the total number of bytes actually written.

The operating system may set a limit (`sysconf()` value `'SC_IOV_MAX'`) on the number of buffers that can be used.

**Availability:** Unix.

*New in version 3.3.*

## Querying the size of a terminal

*New in version 3.3.*

`os.get_terminal_size(fd=STDOUT_FILENO, /)`

Return the size of the terminal window as `(columns, lines)`, tuple of type `terminal_size`.

The optional argument `fd` (default `STDOUT_FILENO`, or standard output) specifies which file descriptor should be queried.

If the file descriptor is not connected to a terminal, an `OSError` is raised.

`shutil.get_terminal_size()` is the high-level function which should normally be used, `os.get_terminal_size` is the low-level implementation.

**Availability:** Unix, Windows.

*class* `os.terminal_size`

A subclass of tuple, holding `(columns, lines)` of the terminal window size.

`columns`

Width of the terminal window in characters.

`lines`

Height of the terminal window in characters.

## Inheritance of File Descriptors

*New in version 3.4.*

A file descriptor has an “inheritable” flag which indicates if the file descriptor can be inherited by child processes. Since Python 3.4, file descriptors created by Python are non-inheritable by default.

On UNIX, non-inheritable file descriptors are closed in child processes at the execution of a new program, other file descriptors are inherited.

On Windows, non-inheritable handles and file descriptors are closed in child processes, except for standard streams (file descriptors 0, 1 and 2: stdin, stdout and stderr), which are always inherited. Using `spawn*` functions, all inheritable handles and all inheritable file descriptors are inherited. Using the `subprocess` module, all file descriptors except standard streams are closed, and inheritable handles are only inherited if the `close_fds` parameter is `False`.

On WebAssembly platforms `wasm32-emscrip`ten and `wasm32-wasi`, the file descriptor cannot be modified.

`os.get_inheritable(fd, /)`

Get the “inheritable” flag of the specified file descriptor (a boolean).

`os.set_inheritable(fd, inheritable, /)`

Set the “inheritable” flag of the specified file descriptor.

`os.get_handle_inheritable(handle, /)`

Get the “inheritable” flag of the specified handle (a boolean).

**Availability:** Windows.

`os.set_handle_inheritable(handle, inheritable, /)`

Set the “inheritable” flag of the specified handle.

**Availability:** Windows.

# Files and Directories

On some Unix platforms, many of these functions support one or more of these features:

- **specifying a file descriptor:** Normally the *path* argument provided to functions in the `os` module must be a string specifying a file path. However, some functions now alternatively accept an open file descriptor for their *path* argument. The function will then operate on the file referred to by the descriptor. (For POSIX systems, Python will call the variant of the function prefixed with `f` (e.g. call `fchdir` instead of `chdir`.)

You can check whether or not *path* can be specified as a file descriptor for a particular function on your platform using `os.supports_fd`. If this functionality is unavailable, using it will raise a `NotImplementedError`.

If the function also supports *dir\_fd* or *follow\_symlinks* arguments, it's an error to specify one of those when supplying *path* as a file descriptor.

- **paths relative to directory descriptors:** If *dir\_fd* is not `None`, it should be a file descriptor referring to a directory, and the path to operate on should be relative; path will then be relative to that directory. If the path is absolute, *dir\_fd* is ignored. (For POSIX systems, Python will call the variant of the function with an `at` suffix and possibly prefixed with `f` (e.g. call `faccessat` instead of `access`).

You can check whether or not *dir\_fd* is supported for a particular function on your platform using `os.supports_dir_fd`. If it's unavailable, using it will raise a `NotImplementedError`.

- **not following symlinks:** If *follow\_symlinks* is `False`, and the last element of the path to operate on is a symbolic link, the function will operate on the symbolic link itself rather than the file pointed to by the link. (For POSIX systems, Python

will call the 1 . . . variant of the function.)

You can check whether or not *follow\_symlinks* is supported for a particular function on your platform using `os.supports_follow_symlinks`. If it's unavailable, using it will raise a `NotImplementedError`.

```
os.access(path, mode, *, dir_fd=None, effective_ids=False,  
follow_symlinks=True)
```

Use the real uid/gid to test for access to *path*. Note that most operations will use the effective uid/gid, therefore this routine can be used in a suid/sgid environment to test if the invoking user has the specified access to *path*. *mode* should be `F_OK` to test the existence of *path*, or it can be the inclusive OR of one or more of `R_OK`, `W_OK`, and `X_OK` to test permissions. Return `True` if access is allowed, `False` if not. See the Unix man page *access(2)* for more information.

This function can support specifying *paths relative to directory descriptors* and *not following symlinks*.

If *effective\_ids* is `True`, `access()` will perform its access checks using the effective uid/gid instead of the real uid/gid. *effective\_ids* may not be supported on your platform; you can check whether or not it is available using `os.supports_effective_ids`. If it is unavailable, using it will raise a `NotImplementedError`.

## Note

Using `access()` to check if a user is authorized to e.g. open a file before actually doing so using `open()` creates a security hole, because the user might exploit the short time interval between checking and opening the file to manipulate it. It's preferable to use *EAFP* techniques. For example:

```
if os.access("myfile", os.R_OK):  
    with open("myfile") as fp:  
        return fp.read()
```

```
return "some default data"
```

is better written as:

```
try:
    fp = open("myfile")
except PermissionError:
    return "some default data"
else:
    with fp:
        return fp.read()
```

### Note

I/O operations may fail even when `access()` indicates that they would succeed, particularly for operations on network filesystems which may have permissions semantics beyond the usual POSIX permission-bit model.

*Changed in version 3.3:* Added the `dir_fd`, `effective_ids`, and `follow_symlinks` parameters.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.F_OK`  
`os.R_OK`  
`os.W_OK`  
`os.X_OK`

Values to pass as the *mode* parameter of `access()` to test the existence, readability, writability and executability of *path*, respectively.

`os.chdir(path)`

Change the current working directory to *path*.

This function can support [specifying a file descriptor](#). The descriptor must refer to an opened directory, not an open file.

This function can raise `OSError` and subclasses such as

`FileNotFoundError`, `PermissionError`, and `NotADirectoryError`.

Raises an [auditing event](#) `os.chdir` with argument `path`.

*New in version 3.3:* Added support for specifying *path* as a file descriptor on some platforms.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.chflags(path, flags, *, follow_symlinks=True)`

Set the flags of *path* to the numeric *flags*. *flags* may take a combination (bitwise OR) of the following values (as defined in the `stat` module):

- `stat.UF_NODUMP`
- `stat.UF_IMMUTABLE`
- `stat.UF_APPEND`
- `stat.UF_OPAQUE`
- `stat.UF_NOUNLINK`
- `stat.UF_COMPRESSED`
- `stat.UF_HIDDEN`
- `stat.SF_ARCHIVED`
- `stat.SF_IMMUTABLE`
- `stat.SF_APPEND`
- `stat.SF_NOUNLINK`
- `stat.SF_SNAPSHOT`

This function can support [not following symlinks](#).

Raises an [auditing event](#) `os.chflags` with arguments `path`, `flags`.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3:* The *follow\_symlinks* argument.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.chmod(path, mode, *, dir_fd=None, follow_symlinks=True)`

Change the mode of *path* to the numeric *mode*. *mode* may take one of the following values (as defined in the `stat` module) or bitwise ORed combinations of them:

- `stat.S_ISUID`
- `stat.S_ISGID`
- `stat.S_ENFMT`
- `stat.S_ISVTX`
- `stat.S_IREAD`
- `stat.S_IWRITE`
- `stat.S_IEXEC`
- `stat.S_IRWXU`
- `stat.S_IRUSR`
- `stat.S_IWUSR`
- `stat.S_IXUSR`
- `stat.S_IRWXG`
- `stat.S_IRGRP`
- `stat.S_IWGRP`
- `stat.S_IXGRP`
- `stat.S_IRWXO`
- `stat.S_IROTH`
- `stat.S_IWOTH`
- `stat.S_IXOTH`

This function can support specifying a file descriptor, paths relative to directory descriptors and not following symlinks.

### Note

Although Windows supports `chmod()`, you can only set the file's read-only flag with it (via the `stat.S_IWRITE` and `stat.S_IREAD` constants or a corresponding integer value). All other bits are ignored.

The function is limited on Emscripten and WASI, see [WebAssembly platforms](#) for more information.

Raises an [auditing event](#) `os.chmod` with arguments `path`, `mode`, `dir_fd`.

*New in version 3.3:* Added support for specifying *path* as an

open file descriptor, and the *dir\_fd* and *follow\_symlinks* arguments.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.chown(path, uid, gid, *, dir_fd=None, follow_symlinks=True)`

Change the owner and group id of *path* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1.

This function can support [specifying a file descriptor](#), [paths relative to directory descriptors](#) and [not following symlinks](#).

See `shutil.chown()` for a higher-level function that accepts names in addition to numeric ids.

Raises an [auditing event](#) `os.chown` with arguments *path*, *uid*, *gid*, *dir\_fd*.

[Availability](#): Unix.

The function is limited on Emscripten and WASI, see [WebAssembly platforms](#) for more information.

*New in version 3.3:* Added support for specifying *path* as an open file descriptor, and the *dir\_fd* and *follow\_symlinks* arguments.

*Changed in version 3.6:* Supports a [path-like object](#).

`os.chroot(path)`

Change the root directory of the current process to *path*.

[Availability](#): Unix, not Emscripten, not WASI.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.fchdir(fd)`

Change the current working directory to the directory represented by the file descriptor *fd*. The descriptor must refer to an opened directory, not an open file. As of Python

3.3, this is equivalent to `os.chdir(fd)`.

Raises an [auditing event](#) `os.chdir` with argument `path`.

[Availability](#): Unix.

`os.getcwd()`

Return a string representing the current working directory.

`os.getcwdb()`

Return a bytestring representing the current working directory.

*Changed in version 3.8:* The function now uses the UTF-8 encoding on Windows, rather than the ANSI code page: see [PEP 529](#) [<https://peps.python.org/pep-0529/>] for the rationale. The function is no longer deprecated on Windows.

`os.lchflags(path, flags)`

Set the flags of *path* to the numeric *flags*, like [chflags\(\)](#), but do not follow symbolic links. As of Python 3.3, this is equivalent to `os.chflags(path, flags, follow_symlinks=False)`.

Raises an [auditing event](#) `os.chflags` with arguments `path`, `flags`.

[Availability](#): Unix, not Emscripten, not WASI.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.lchmod(path, mode)`

Change the mode of *path* to the numeric *mode*. If *path* is a symlink, this affects the symlink rather than the target. See the docs for [chmod\(\)](#) for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(path, mode, follow_symlinks=False)`.

Raises an [auditing event](#) `os.chmod` with arguments `path`,

mode, dir\_fd.

**Availability:** Unix.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.lchown(path, uid, gid)`

Change the owner and group id of *path* to the numeric *uid* and *gid*. This function will not follow symbolic links. As of Python 3.3, this is equivalent to `os.chown(path, uid, gid, follow_symlinks=False)`.

Raises an [auditing event](#) `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

**Availability:** Unix.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.link(src, dst, *, src_dir_fd=None, dst_dir_fd=None, follow_symlinks=True)`

Create a hard link pointing to *src* named *dst*.

This function can support specifying *src\_dir\_fd* and/or *dst\_dir\_fd* to supply [paths relative to directory descriptors](#), and [not following symlinks](#).

Raises an [auditing event](#) `os.link` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

**Availability:** Unix, Windows.

*Changed in version 3.2:* Added Windows support.

*New in version 3.3:* Added the *src\_dir\_fd*, *dst\_dir\_fd*, and *follow\_symlinks* arguments.

*Changed in version 3.6:* Accepts a [path-like object](#) for *src* and *dst*.

`os.listdir(path='.')`

Return a list containing the names of the entries in the directory given by *path*. The list is in arbitrary order, and does not include the special entries `'.'` and `'..'` even if they are present in the directory. If a file is removed from or added to the directory during the call of this function, whether a name for that file be included is unspecified.

*path* may be a [path-like object](#). If *path* is of type `bytes` (directly or indirectly through the [PathLike](#) interface), the filenames returned will also be of type `bytes`; in all other circumstances, they will be of type `str`.

This function can also support [specifying a file descriptor](#); the file descriptor must refer to a directory.

Raises an [auditing event](#) `os.listdir` with argument *path*.

### Note

To encode `str` filenames to `bytes`, use [fsencode\(\)](#).

### See also

The [scandir\(\)](#) function returns directory entries along with file attribute information, giving better performance for many common use cases.

*Changed in version 3.2:* The *path* parameter became optional.

*New in version 3.3:* Added support for specifying *path* as an open file descriptor.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.lstat(path, *, dir_fd=None)`

Perform the equivalent of an `lstat()` system call on the given path. Similar to [stat\(\)](#), but does not follow symbolic links. Return a [stat\\_result](#) object.

On platforms that do not support symbolic links, this is an alias for `stat()`.

As of Python 3.3, this is equivalent to `os.stat(path, dir_fd=dir_fd, follow_symlinks=False)`.

This function can also support [paths relative to directory descriptors](#).

### See also

The `stat()` function.

*Changed in version 3.2:* Added support for Windows 6.0 (Vista) symbolic links.

*Changed in version 3.3:* Added the `dir_fd` parameter.

*Changed in version 3.6:* Accepts a [path-like object](#).

*Changed in version 3.8:* On Windows, now opens reparse points that represent another path (name surrogates), including symbolic links and directory junctions. Other kinds of reparse points are resolved by the operating system as for `stat()`.

`os.mkdir(path, mode=0o777, *, dir_fd=None)`

Create a directory named *path* with numeric mode *mode*.

If the directory already exists, `FileExistsError` is raised. If a parent directory in the path does not exist, `FileNotFoundError` is raised.

On some systems, *mode* is ignored. Where it is used, the current umask value is first masked out. If bits other than the last 9 (i.e. the last 3 digits of the octal representation of the *mode*) are set, their meaning is platform-dependent. On some platforms, they are ignored and you should call `chmod()` explicitly to set them.

This function can also support [paths relative to directory](#)

descriptors.

It is also possible to create temporary directories; see the [tempfile](#) module's `tempfile.mkdtemp()` function.

Raises an [auditing event](#) `os.mkdir` with arguments `path`, `mode`, `dir_fd`.

*New in version 3.3:* The `dir_fd` argument.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.makedirs(name, mode=0o777, exist_ok=False)`

Recursive directory creation function. Like `mkdir()`, but makes all intermediate-level directories needed to contain the leaf directory.

The `mode` parameter is passed to `mkdir()` for creating the leaf directory; see [the mkdir\(\) description](#) for how it is interpreted. To set the file permission bits of any newly created parent directories you can set the umask before invoking `makedirs()`. The file permission bits of existing parent directories are not changed.

If `exist_ok` is `False` (the default), a [FileExistsError](#) is raised if the target directory already exists.

### Note

`makedirs()` will become confused if the path elements to create include [pardir](#) (eg. `..` on UNIX systems).

This function handles UNC paths correctly.

Raises an [auditing event](#) `os.mkdir` with arguments `path`, `mode`, `dir_fd`.

*New in version 3.2:* The `exist_ok` parameter.

*Changed in version 3.4.1:* Before Python 3.4.1, if `exist_ok` was `True` and the directory existed, `makedirs()` would still

raise an error if *mode* did not match the mode of the existing directory. Since this behavior was impossible to implement safely, it was removed in Python 3.4.1. See [bpo-21082](https://bugs.python.org/issue?@action=redirect&bpo=21082) [https://bugs.python.org/issue?@action=redirect&bpo=21082].

*Changed in version 3.6:* Accepts a [path-like object](#).

*Changed in version 3.7:* The *mode* argument no longer affects the file permission bits of newly created intermediate-level directories.

`os.mkfifo(path, mode=0o666, *, dir_fd=None)`

Create a FIFO (a named pipe) named *path* with numeric mode *mode*. The current umask value is first masked out from the mode.

This function can also support [paths relative to directory descriptors](#).

FIFOs are pipes that can be accessed like regular files. FIFOs exist until they are deleted (for example with `os.unlink()`). Generally, FIFOs are used as rendezvous between “client” and “server” type processes: the server opens the FIFO for reading, and the client opens it for writing. Note that `mkfifo()` doesn’t open the FIFO — it just creates the rendezvous point.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3:* The *dir\_fd* argument.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.mknod(path, mode=0o600, device=0, *, dir_fd=None)`

Create a filesystem node (file, device special file or named pipe) named *path*. *mode* specifies both the permissions to use and the type of node to be created, being combined (bitwise OR) with one of `stat.S_IFREG`, `stat.S_IFCHR`, `stat.S_IFBLK`, and `stat.S_IFIFO` (those constants are available in [stat](#)). For `stat.S_IFCHR` and

`stat.S_IFBLK`, *device* defines the newly created device special file (probably using `os.makedev()`), otherwise it is ignored.

This function can also support [paths relative to directory descriptors](#).

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3:* The *dir\_fd* argument.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.major(device, /)`

Extract the device major number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.minor(device, /)`

Extract the device minor number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.makedev(major, minor, /)`

Compose a raw device number from the major and minor device numbers.

`os.pathconf(path, name)`

Return system configuration information relevant to a named file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an

**OSError** is raised with `errno.EINVAL` for the error number.

This function can support [specifying a file descriptor](#).

[Availability](#): Unix.

*Changed in version 3.6:* Accepts a [path-like object](#).

## `os.pathconf_names`

Dictionary mapping names accepted by `pathconf()` and `fpathconf()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

[Availability](#): Unix.

## `os.readlink(path, *, dir_fd=None)`

Return a string representing the path to which the symbolic link points. The result may be either an absolute or relative pathname; if it is relative, it may be converted to an absolute pathname using

```
os.path.join(os.path.dirname(path), result).
```

If the *path* is a string object (directly or indirectly through a [PathLike](#) interface), the result will also be a string object, and the call may raise a `UnicodeDecodeError`. If the *path* is a bytes object (direct or indirectly), the result will be a bytes object.

This function can also support [paths relative to directory descriptors](#).

When trying to resolve a path that may contain links, use `realpath()` to properly handle recursion and platform differences.

[Availability](#): Unix, Windows.

*Changed in version 3.2:* Added support for Windows 6.0 (Vista) symbolic links.

*New in version 3.3:* The `dir_fd` argument.

*Changed in version 3.6:* Accepts a [path-like object](#) on Unix.

*Changed in version 3.8:* Accepts a [path-like object](#) and a bytes object on Windows.

*Changed in version 3.8:* Added support for directory junctions, and changed to return the substitution path (which typically includes `\\?\\` prefix) rather than the optional “print name” field that was previously returned.

`os.remove(path, *, dir_fd=None)`

Remove (delete) the file *path*. If *path* is a directory, an **OSError** is raised. Use `rmdir()` to remove directories. If the file does not exist, a **FileNotFoundError** is raised.

This function can support [paths relative to directory descriptors](#).

On Windows, attempting to remove a file that is in use causes an exception to be raised; on Unix, the directory entry is removed but the storage allocated to the file is not made available until the original file is no longer in use.

This function is semantically identical to `unlink()`.

Raises an [auditing event](#) `os.remove` with arguments `path`, `dir_fd`.

*New in version 3.3:* The `dir_fd` argument.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.removedirs(name)`

Remove directories recursively. Works like `rmdir()` except that, if the leaf directory is successfully removed, `removedirs()` tries to successively remove every parent directory mentioned in *path* until an error is raised (which is ignored, because it generally means that a parent directory is

not empty). For example, `os.removedirs('foo/bar/baz')` will first remove the directory `'foo/bar/baz'`, and then remove `'foo/bar'` and `'foo'` if they are empty. Raises **OSError** if the leaf directory could not be successfully removed.

Raises an **auditing event** `os.remove` with arguments `path`, `dir_fd`.

*Changed in version 3.6:* Accepts a **path-like object**.

`os.rename(src, dst, *, src_dir_fd=None, dst_dir_fd=None)`

Rename the file or directory `src` to `dst`. If `dst` exists, the operation will fail with an **OSError** subclass in a number of cases:

On Windows, if `dst` exists a **FileExistsError** is always raised. The operation may fail if `src` and `dst` are on different filesystems. Use **shutil.move()** to support moves to a different filesystem.

On Unix, if `src` is a file and `dst` is a directory or vice-versa, an **IsADirectoryError** or a **NotADirectoryError** will be raised respectively. If both are directories and `dst` is empty, `dst` will be silently replaced. If `dst` is a non-empty directory, an **OSError** is raised. If both are files, `dst` will be replaced silently if the user has permission. The operation may fail on some Unix flavors if `src` and `dst` are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying `src_dir_fd` and/or `dst_dir_fd` to supply **paths relative to directory descriptors**.

If you want cross-platform overwriting of the destination, use **replace()**.

Raises an **auditing event** `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

*New in version 3.3:* The `src_dir_fd` and `dst_dir_fd` arguments.

*Changed in version 3.6:* Accepts a [path-like object](#) for *src* and *dst*.

`os.rename(old, new)`

Recursive directory or file renaming function. Works like [rename\(\)](#), except creation of any intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned away using [removedirs\(\)](#).

### Note

This function can fail with the new directory structure made if you lack permissions needed to remove the leaf directory or file.

Raises an [auditing event](#) `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

*Changed in version 3.6:* Accepts a [path-like object](#) for *old* and *new*.

`os.replace(src, dst, *, src_dir_fd=None, dst_dir_fd=None)`

Rename the file or directory *src* to *dst*. If *dst* is a non-empty directory, [OSError](#) will be raised. If *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src\_dir\_fd* and/or *dst\_dir\_fd* to supply [paths relative to directory descriptors](#).

Raises an [auditing event](#) `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

*New in version 3.3.*

*Changed in version 3.6:* Accepts a [path-like object](#) for *src* and

*dst*.

`os.rmdir(path, *, dir_fd=None)`

Remove (delete) the directory *path*. If the directory does not exist or is not empty, a `FileNotFoundError` or an `OSError` is raised respectively. In order to remove whole directory trees, `shutil.rmtree()` can be used.

This function can support [paths relative to directory descriptors](#).

Raises an [auditing event](#) `os.rmdir` with arguments `path`, `dir_fd`.

*New in version 3.3:* The `dir_fd` parameter.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.scandir(path='.')`

Return an iterator of `os.DirEntry` objects corresponding to the entries in the directory given by *path*. The entries are yielded in arbitrary order, and the special entries `'.'` and `'..'` are not included. If a file is removed from or added to the directory after creating the iterator, whether an entry for that file be included is unspecified.

Using `scandir()` instead of `listdir()` can significantly increase the performance of code that also needs file type or file attribute information, because `os.DirEntry` objects expose this information if the operating system provides it when scanning a directory. All `os.DirEntry` methods may perform a system call, but `is_dir()` and `is_file()` usually only require a system call for symbolic links; `os.DirEntry.stat()` always requires a system call on Unix but only requires one for symbolic links on Windows.

*path* may be a [path-like object](#). If *path* is of type `bytes` (directly or indirectly through the [PathLike](#) interface), the type of the `name` and `path` attributes of each `os.DirEntry` will be `bytes`; in all other circumstances,

they will be of type `str`.

This function can also support [specifying a file descriptor](#); the file descriptor must refer to a directory.

Raises an [auditing event](#) `os.scandir` with argument `path`.

The `scandir()` iterator supports the [context manager](#) protocol and has the following method:

`scandir.close()`

Close the iterator and free acquired resources.

This is called automatically when the iterator is exhausted or garbage collected, or when an error happens during iterating. However it is advisable to call it explicitly or use the [with](#) statement.

*New in version 3.6.*

The following example shows a simple use of `scandir()` to display all the files (excluding directories) in the given *path* that don't start with `'.'`. The `entry.is_file()` call will generally not make an additional system call:

```
with os.scandir(path) as it:
    for entry in it:
        if not entry.name.startswith('.') and entry.is_file():
            print(entry.name)
```

## Note

On Unix-based systems, `scandir()` uses the system's [opendir\(\)](https://pubs.opengroup.org/onlinepubs/009695399/functions/opendir.html) [https://pubs.opengroup.org/onlinepubs/009695399/functions/opendir.html] and [readdir\(\)](https://pubs.opengroup.org/onlinepubs/009695399/functions/readdir_r.html) [https://pubs.opengroup.org/onlinepubs/009695399/functions/readdir\_r.html] functions. On Windows, it uses the Win32 [FindFirstFileW](https://msdn.microsoft.com/en-us/library/windows/desktop/aa364418(v=vs.85).aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa364418(v=vs.85).aspx] and [FindNextFileW](https://msdn.microsoft.com/en-us/library/windows/desktop/aa364428(v=vs.85).aspx) [https://msdn.microsoft.com/en-us/library/windows/desktop/aa364428(v=vs.85).aspx] functions.

*New in version 3.5.*

*New in version 3.6:* Added support for the [context manager](#) protocol and the [close\(\)](#) method. If a [scandir\(\)](#) iterator is neither exhausted nor explicitly closed a [ResourceWarning](#) will be emitted in its destructor.

The function accepts a [path-like object](#).

*Changed in version 3.7:* Added support for [file descriptors](#) on Unix.

*class* `os.DirEntry`

Object yielded by [scandir\(\)](#) to expose the file path and other file attributes of a directory entry.

[scandir\(\)](#) will provide as much of this information as possible without making additional system calls. When a `stat()` or `lstat()` system call is made, the `os.DirEntry` object will cache the result.

`os.DirEntry` instances are not intended to be stored in long-lived data structures; if you know the file metadata has changed or if a long time has elapsed since calling [scandir\(\)](#), call `os.stat(entry.path)` to fetch up-to-date information.

Because the `os.DirEntry` methods can make operating system calls, they may also raise [OSError](#). If you need very fine-grained control over errors, you can catch [OSError](#) when calling one of the `os.DirEntry` methods and handle as appropriate.

To be directly usable as a [path-like object](#), `os.DirEntry` implements the [PathLike](#) interface.

Attributes and methods on a `os.DirEntry` instance are as follows:

`name`

The entry's base filename, relative to the [scandir\(\)](#)

*path* argument.

The `name` attribute will be `bytes` if the `scandir()` *path* argument is of type `bytes` and `str` otherwise. Use `fsdecode()` to decode byte filenames.

## `path`

The entry's full path name: equivalent to `os.path.join(scandir_path, entry.name)` where *scandir\_path* is the `scandir()` *path* argument. The path is only absolute if the `scandir()` *path* argument was absolute. If the `scandir()` *path* argument was a `file descriptor`, the `path` attribute is the same as the `name` attribute.

The `path` attribute will be `bytes` if the `scandir()` *path* argument is of type `bytes` and `str` otherwise. Use `fsdecode()` to decode byte filenames.

## `inode()`

Return the inode number of the entry.

The result is cached on the `os.DirEntry` object. Use `os.stat(entry.path, follow_symlinks=False).st_ino` to fetch up-to-date information.

On the first, uncached call, a system call is required on Windows but not on Unix.

## `is_dir(*, follow_symlinks=True)`

Return `True` if this entry is a directory or a symbolic link pointing to a directory; return `False` if the entry is or points to any other kind of file, or if it doesn't exist anymore.

If *follow\_symlinks* is `False`, return `True` only if this entry is a directory (without following symlinks); return `False` if the entry is any other kind of file or if it

doesn't exist anymore.

The result is cached on the `os.DirEntry` object, with a separate cache for *follow\_symlinks* `True` and `False`. Call `os.stat()` along with `stat.S_ISDIR()` to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, for non-symlinks, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`. If the entry is a symlink, a system call will be required to follow the symlink unless *follow\_symlinks* is `False`.

This method can raise `OSError`, such as `PermissionError`, but `FileNotFoundError` is caught and not raised.

`is_file(*, follow_symlinks = True)`

Return `True` if this entry is a file or a symbolic link pointing to a file; return `False` if the entry is or points to a directory or other non-file entry, or if it doesn't exist anymore.

If *follow\_symlinks* is `False`, return `True` only if this entry is a file (without following symlinks); return `False` if the entry is a directory or other non-file entry, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Caching, system calls made, and exceptions raised are as per `is_dir()`.

`is_symlink()`

Return `True` if this entry is a symbolic link (even if broken); return `False` if the entry points to a directory or any kind of file, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Call

`os.path.islink()` to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`.

This method can raise `OSError`, such as `PermissionError`, but `FileNotFoundError` is caught and not raised.

`stat(*, follow_symlinks=True)`

Return a `stat_result` object for this entry. This method follows symbolic links by default; to stat a symbolic link add the `follow_symlinks=False` argument.

On Unix, this method always requires a system call. On Windows, it only requires a system call if `follow_symlinks` is `True` and the entry is a reparse point (for example, a symbolic link or directory junction).

On Windows, the `st_ino`, `st_dev` and `st_nlink` attributes of the `stat_result` are always set to zero. Call `os.stat()` to get these attributes.

The result is cached on the `os.DirEntry` object, with a separate cache for `follow_symlinks` `True` and `False`. Call `os.stat()` to fetch up-to-date information.

Note that there is a nice correspondence between several attributes and methods of `os.DirEntry` and of `pathlib.Path`. In particular, the `name` attribute has the same meaning, as do the `is_dir()`, `is_file()`, `is_symlink()` and `stat()` methods.

*New in version 3.5.*

*Changed in version 3.6:* Added support for the `PathLike`

interface. Added support for **bytes** paths on Windows.

`os.stat(path, *, dir_fd=None, follow_symlinks=True)`

Get the status of a file or a file descriptor. Perform the equivalent of a **stat()** system call on the given path. *path* may be specified as either a string or bytes – directly or indirectly through the **PathLike** interface – or as an open file descriptor. Return a **stat\_result** object.

This function normally follows symlinks; to stat a symlink add the argument `follow_symlinks=False`, or use **lstat()**.

This function can support **specifying a file descriptor** and **not following symlinks**.

On Windows, passing `follow_symlinks=False` will disable following all name-surrogate reparse points, which includes symlinks and directory junctions. Other types of reparse points that do not resemble links or that the operating system is unable to follow will be opened directly. When following a chain of multiple links, this may result in the original link being returned instead of the non-link that prevented full traversal. To obtain stat results for the final path in this case, use the **os.path.realpath()** function to resolve the path name as far as possible and call **lstat()** on the result. This does not apply to dangling symlinks or junction points, which will raise the usual exceptions.

Example:

```
>>> import os
>>> statinfo = os.stat('somefile.txt')
>>> statinfo
os.stat_result(st_mode=33188, st_ino=7876932, st_dev=
st_nlink=1, st_uid=501, st_gid=501, st_size=264, st_
st_mtime=1297230027, st_ctime=1297230027)
>>> statinfo.st_size
264
```

**See also**

`fstat()` and `lstat()` functions.

*New in version 3.3:* Added the `dir_fd` and `follow_symlinks` arguments, specifying a file descriptor instead of a path.

*Changed in version 3.6:* Accepts a [path-like object](#).

*Changed in version 3.8:* On Windows, all reparse points that can be resolved by the operating system are now followed, and passing `follow_symlinks=False` disables following all name surrogate reparse points. If the operating system reaches a reparse point that it is not able to follow, `stat` now returns the information for the original path as if `follow_symlinks=False` had been specified instead of raising an error.

`class os.stat_result`

Object whose attributes correspond roughly to the members of the `stat` structure. It is used for the result of `os.stat()`, `os.fstat()` and `os.lstat()`.

Attributes:

`st_mode`

File mode: file type and file mode bits (permissions).

`st_ino`

Platform dependent, but if non-zero, uniquely identifies the file for a given value of `st_dev`. Typically:

- the inode number on Unix,
- the [file index](https://msdn.microsoft.com/en-us/library/aa363788) [https://msdn.microsoft.com/en-us/library/aa363788] on Windows

`st_dev`

Identifier of the device on which this file resides.

`st_nlink`

Number of hard links.

`st_uid`

User identifier of the file owner.

`st_gid`

Group identifier of the file owner.

`st_size`

Size of the file in bytes, if it is a regular file or a symbolic link. The size of a symbolic link is the length of the pathname it contains, without a terminating null byte.

Timestamps:

`st_atime`

Time of most recent access expressed in seconds.

`st_mtime`

Time of most recent content modification expressed in seconds.

`st_ctime`

Platform dependent:

- the time of most recent metadata change on Unix,
- the time of creation on Windows, expressed in seconds.

`st_atime_ns`

Time of most recent access expressed in nanoseconds as an integer.

`st_mtime_ns`

Time of most recent content modification expressed in nanoseconds as an integer.

`st_ctime_ns`

Platform dependent:

- the time of most recent metadata change on Unix,
- the time of creation on Windows, expressed in nanoseconds as an integer.

### Note

The exact meaning and resolution of the `st_atime`, `st_mtime`, and `st_ctime` attributes depend on the operating system and the file system. For example, on Windows systems using the FAT or FAT32 file systems, `st_mtime` has 2-second resolution, and `st_atime` has only 1-day resolution. See your operating system documentation for details.

Similarly, although `st_atime_ns`, `st_mtime_ns`, and `st_ctime_ns` are always expressed in nanoseconds, many systems do not provide nanosecond precision. On systems that do provide nanosecond precision, the floating-point object used to store `st_atime`, `st_mtime`, and `st_ctime` cannot preserve all of it, and as such will be slightly inexact. If you need the exact timestamps you should always use `st_atime_ns`, `st_mtime_ns`, and `st_ctime_ns`.

On some Unix systems (such as Linux), the following attributes may also be available:

`st_blocks`

Number of 512-byte blocks allocated for file. This may be smaller than `st_size`/512 when the file has holes.

`st_blksize`

“Preferred” blocksize for efficient file system I/O. Writing to a file in smaller chunks may cause an inefficient read-modify-rewrite.

`st_rdev`

Type of device if an inode device.

`st_flags`

User defined flags for file.

On other Unix systems (such as FreeBSD), the following attributes may be available (but may be only filled out if root tries to use them):

`st_gen`

File generation number.

`st_birthtime`

Time of file creation.

On Solaris and derivatives, the following attributes may also be available:

`st_fstype`

String that uniquely identifies the type of the filesystem that contains the file.

On macOS systems, the following attributes may also be available:

`st_rsize`

Real size of the file.

`st_creator`

Creator of the file.

`st_type`

File type.

On Windows systems, the following attributes are also available:

## st\_file\_attributes

Windows file attributes: `dwFileAttributes` member of the `BY_HANDLE_FILE_INFORMATION` structure returned by `GetFileInformationByHandle()`. See the `FILE_ATTRIBUTE_*` constants in the `stat` module.

## st\_reparse\_tag

When `st_file_attributes` has the `FILE_ATTRIBUTE_REPARSE_POINT` set, this field contains the tag identifying the type of reparse point. See the `IO_REPARSE_TAG_*` constants in the `stat` module.

The standard module `stat` defines functions and constants that are useful for extracting information from a `stat` structure. (On Windows, some items are filled with dummy values.)

For backward compatibility, a `stat_result` instance is also accessible as a tuple of at least 10 integers giving the most important (and portable) members of the `stat` structure, in the order `st_mode`, `st_ino`, `st_dev`, `st_nlink`, `st_uid`, `st_gid`, `st_size`, `st_atime`, `st_mtime`, `st_ctime`. More items may be added at the end by some implementations. For compatibility with older Python versions, accessing `stat_result` as a tuple always returns integers.

*New in version 3.3:* Added the `st_atime_ns`, `st_mtime_ns`, and `st_ctime_ns` members.

*New in version 3.5:* Added the `st_file_attributes` member on Windows.

*Changed in version 3.5:* Windows now returns the file index as `st_ino` when available.

*New in version 3.7:* Added the `st_fstype` member to Solaris/derivatives.

*New in version 3.8:* Added the `st_reparse_tag` member on Windows.

*Changed in version 3.8:* On Windows, the `st_mode` member now identifies special files as `S_IFCHR`, `S_IFIFO` or `S_IFBLK` as appropriate.

`os.statvfs(path)`

Perform a `statvfs()` system call on the given path. The return value is an object whose attributes describe the filesystem on the given path, and correspond to the members of the `statvfs` structure, namely: `f_bsize`, `f_frsize`, `f_blocks`, `f_bfree`, `f_bavail`, `f_files`, `f_ffree`, `f_favail`, `f_flag`, `f_namemax`, `f_fsid`.

Two module-level constants are defined for the `f_flag` attribute's bit-flags: if `ST_RDONLY` is set, the filesystem is mounted read-only, and if `ST_NOSUID` is set, the semantics of `setuid`/`setgid` bits are disabled or not supported.

Additional module-level constants are defined for GNU/glibc based systems. These are `ST_NODEV` (disallow access to device special files), `ST_NOEXEC` (disallow program execution), `ST_SYNCHRONOUS` (writes are synced at once), `ST_MANDLOCK` (allow mandatory locks on an FS), `ST_WRITE` (write on file/directory/symlink), `ST_APPEND` (append-only file), `ST_IMMUTABLE` (immutable file), `ST_NOATIME` (do not update access times), `ST_NODIRATIME` (do not update directory access times), `ST_RELATIME` (update atime relative to mtime/ctime).

This function can support [specifying a file descriptor](#).

**Availability:** Unix.

*Changed in version 3.2:* The `ST_RDONLY` and `ST_NOSUID` constants were added.

*New in version 3.3:* Added support for specifying `path` as an open file descriptor.

*Changed in version 3.4:* The `ST_NODEV`, `ST_NOEXEC`, `ST_SYNCHRONOUS`, `ST_MANDLOCK`, `ST_WRITE`, `ST_APPEND`, `ST_IMMUTABLE`, `ST_NOATIME`, `ST_NODIRATIME`, and `ST_RELATIME` constants were added.

*Changed in version 3.6:* Accepts a [path-like object](#).

*New in version 3.7:* Added `f_fsid`.

## `os.supports_dir_fd`

A [set](#) object indicating which functions in the `os` module accept an open file descriptor for their `dir_fd` parameter. Different platforms provide different features, and the underlying functionality Python uses to implement the `dir_fd` parameter is not available on all platforms Python supports. For consistency's sake, functions that may support `dir_fd` always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `None` for `dir_fd` is always supported on all platforms.)

To check whether a particular function accepts an open file descriptor for its `dir_fd` parameter, use the `in` operator on `supports_dir_fd`. As an example, this expression evaluates to `True` if `os.stat()` accepts open file descriptors for `dir_fd` on the local platform:

```
os.stat in os.supports_dir_fd
```

Currently `dir_fd` parameters only work on Unix platforms; none of them work on Windows.

*New in version 3.3.*

## `os.supports_effective_ids`

A [set](#) object indicating whether `os.access()` permits specifying `True` for its `effective_ids` parameter on the local platform. (Specifying `False` for `effective_ids` is always supported on all platforms.) If the local platform supports it, the collection will contain `os.access()`; otherwise it will

be empty.

This expression evaluates to `True` if `os.access()` supports `effective_ids=True` on the local platform:

```
os.access in os.supports_effective_ids
```

Currently *effective\_ids* is only supported on Unix platforms; it does not work on Windows.

*New in version 3.3.*

## `os.supports_fd`

A `set` object indicating which functions in the `os` module permit specifying their *path* parameter as an open file descriptor on the local platform. Different platforms provide different features, and the underlying functionality Python uses to accept open file descriptors as *path* arguments is not available on all platforms Python supports.

To determine whether a particular function permits specifying an open file descriptor for its *path* parameter, use the `in` operator on `supports_fd`. As an example, this expression evaluates to `True` if `os.chdir()` accepts open file descriptors for *path* on your local platform:

```
os.chdir in os.supports_fd
```

*New in version 3.3.*

## `os.supports_follow_symlinks`

A `set` object indicating which functions in the `os` module accept `False` for their *follow\_symlinks* parameter on the local platform. Different platforms provide different features, and the underlying functionality Python uses to implement *follow\_symlinks* is not available on all platforms Python supports. For consistency's sake, functions that may support *follow\_symlinks* always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `True` for *follow\_symlinks* is

always supported on all platforms.)

To check whether a particular function accepts `False` for its `follow_symlinks` parameter, use the `in` operator on `supports_follow_symlinks`. As an example, this expression evaluates to `True` if you may specify `follow_symlinks=False` when calling `os.stat()` on the local platform:

```
os.stat in os.supports_follow_symlinks
```

*New in version 3.3.*

`os.symlink(src, dst, target_is_directory=False, *, dir_fd=None)`

Create a symbolic link pointing to `src` named `dst`.

On Windows, a symlink represents either a file or a directory, and does not morph to the target dynamically. If the target is present, the type of the symlink will be created to match. Otherwise, the symlink will be created as a directory if `target_is_directory` is `True` or a file symlink (the default) otherwise. On non-Windows platforms, `target_is_directory` is ignored.

This function can support [paths relative to directory descriptors](#).

### Note

On newer versions of Windows 10, unprivileged accounts can create symlinks if Developer Mode is enabled. When Developer Mode is not available/enabled, the `SeCreateSymbolicLinkPrivilege` privilege is required, or the process must be run as an administrator.

`OSError` is raised when the function is called by an unprivileged user.

Raises an [auditing event](#) `os.symlink` with arguments `src`, `dst`, `dir_fd`.

**Availability:** Unix, Windows.

The function is limited on Emscripten and WASI, see [WebAssembly platforms](#) for more information.

*Changed in version 3.2:* Added support for Windows 6.0 (Vista) symbolic links.

*New in version 3.3:* Added the `dir_fd` argument, and now allow `target_is_directory` on non-Windows platforms.

*Changed in version 3.6:* Accepts a [path-like object](#) for `src` and `dst`.

*Changed in version 3.8:* Added support for unelevated symlinks on Windows with Developer Mode.

`os.sync()`

Force write of everything to disk.

**Availability:** Unix.

*New in version 3.3.*

`os.truncate(path, length)`

Truncate the file corresponding to `path`, so that it is at most `length` bytes in size.

This function can support [specifying a file descriptor](#).

Raises an [auditing event](#) `os.truncate` with arguments `path`, `length`.

**Availability:** Unix, Windows.

*New in version 3.3.*

*Changed in version 3.5:* Added support for Windows

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.unlink(path, *, dir_fd=None)`

Remove (delete) the file *path*. This function is semantically identical to `remove()`; the `unlink` name is its traditional Unix name. Please see the documentation for `remove()` for further information.

Raises an [auditing event](#) `os.remove` with arguments `path`, `dir_fd`.

*New in version 3.3:* The `dir_fd` parameter.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.utime(path, times=None, *, [ns, ]dir_fd=None, follow_symlinks=True)`

Set the access and modified times of the file specified by *path*.

`utime()` takes two optional parameters, *times* and *ns*. These specify the times set on *path* and are used as follows:

- If *ns* is specified, it must be a 2-tuple of the form `(atime_ns, mtime_ns)` where each member is an int expressing nanoseconds.
- If *times* is not `None`, it must be a 2-tuple of the form `(atime, mtime)` where each member is an int or float expressing seconds.
- If *times* is `None` and *ns* is unspecified, this is equivalent to specifying `ns=(atime_ns, mtime_ns)` where both times are the current time.

It is an error to specify tuples for both *times* and *ns*.

Note that the exact times you set here may not be returned by a subsequent `stat()` call, depending on the resolution with which your operating system records access and modification times; see `stat()`. The best way to preserve exact times is to use the `st_atime_ns` and `st_mtime_ns` fields from the `os.stat()` result object with the *ns* parameter to `utime()`.

This function can support [specifying a file descriptor](#), [paths](#)

relative to directory descriptors and not following symlinks.

Raises an [auditing event](#) `os.utime` with arguments `path`, `times`, `ns`, `dir_fd`.

*New in version 3.3:* Added support for specifying `path` as an open file descriptor, and the `dir_fd`, `follow_symlinks`, and `ns` parameters.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.walk(top, topdown=True, onerror=None, followlinks=False)`

Generate the file names in a directory tree by walking the tree either top-down or bottom-up. For each directory in the tree rooted at directory *top* (including *top* itself), it yields a 3-tuple (*dirpath*, *dirnames*, *filenames*).

*dirpath* is a string, the path to the directory. *dirnames* is a list of the names of the subdirectories in *dirpath* (including symlinks to directories, and excluding `'.'` and `'..'`). *filenames* is a list of the names of the non-directory files in *dirpath*. Note that the names in the lists contain no path components. To get a full path (which begins with *top*) to a file or directory in *dirpath*, do `os.path.join(dirpath, name)`. Whether or not the lists are sorted depends on the file system. If a file is removed from or added to the *dirpath* directory during generating the lists, whether a name for that file be included is unspecified.

If optional argument *topdown* is `True` or not specified, the triple for a directory is generated before the triples for any of its subdirectories (directories are generated top-down). If *topdown* is `False`, the triple for a directory is generated after the triples for all of its subdirectories (directories are generated bottom-up). No matter the value of *topdown*, the list of subdirectories is retrieved before the tuples for the directory and its subdirectories are generated.

When *topdown* is `True`, the caller can modify the *dirnames* list in-place (perhaps using [del](#) or slice assignment), and

`walk()` will only recurse into the subdirectories whose names remain in *dirnames*; this can be used to prune the search, impose a specific order of visiting, or even to inform `walk()` about directories the caller creates or renames before it resumes `walk()` again. Modifying *dirnames* when *topdown* is `False` has no effect on the behavior of the walk, because in bottom-up mode the directories in *dirnames* are generated before *dirpath* itself is generated.

By default, errors from the `scandir()` call are ignored. If optional argument *onerror* is specified, it should be a function; it will be called with one argument, an `OSError` instance. It can report the error to continue with the walk, or raise the exception to abort the walk. Note that the filename is available as the `filename` attribute of the exception object.

By default, `walk()` will not walk down into symbolic links that resolve to directories. Set *followlinks* to `True` to visit directories pointed to by symlinks, on systems that support them.

### Note

Be aware that setting *followlinks* to `True` can lead to infinite recursion if a link points to a parent directory of itself. `walk()` does not keep track of the directories it visited already.

### Note

If you pass a relative pathname, don't change the current working directory between resumptions of `walk()`. `walk()` never changes the current directory, and assumes that its caller doesn't either.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
```

```

from os.path import join, getsize
for root, dirs, files in os.walk('python/Lib/email'):
    print(root, "consumes", end=" ")
    print(sum(getsize(join(root, name)) for name in files), end=" ")
    print("bytes in", len(files), "non-directory files")
    if 'CVS' in dirs:
        dirs.remove('CVS') # don't visit CVS directories

```

In the next example (simple implementation of `shutil.rmtree()`), walking the tree bottom-up is essential, `rmdir()` doesn't allow deleting a directory before the directory is empty:

```

# Delete everything reachable from the directory named top
# assuming there are no symbolic links.
# CAUTION: This is dangerous! For example, if top is a
# could delete all your disk files.
import os
for root, dirs, files in os.walk(top, topdown=False):
    for name in files:
        os.remove(os.path.join(root, name))
    for name in dirs:
        os.rmdir(os.path.join(root, name))

```

Raises an `os.error` if `os.walk` with arguments `top`, `topdown`, `onerror`, `followlinks`.

*Changed in version 3.5:* This function now calls `os.scandir()` instead of `os.listdir()`, making it faster by reducing the number of calls to `os.stat()`.

*Changed in version 3.6:* Accepts a `path-like object`.

`os.fwalk(top='.', topdown=True, onerror=None, *, follow_symlinks=False, dir_fd=None)`

This behaves exactly like `walk()`, except that it yields a 4-tuple (`dirpath`, `dirnames`, `filenames`, `dirfd`), and it supports `dir_fd`.

*dirpath*, *dirnames* and *filenames* are identical to `walk()` output, and *dirfd* is a file descriptor referring to the directory *dirpath*.

This function always supports [paths relative to directory descriptors](#) and [not following symlinks](#). Note however that, unlike other functions, the `fwalk()` default value for *follow\_symlinks* is `False`.

### Note

Since `fwalk()` yields file descriptors, those are only valid until the next iteration step, so you should duplicate them (e.g. with `dup()`) if you want to keep them longer.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
for root, dirs, files, rootfd in os.fwalk('python/L
    print(root, "consumes", end="")
    print(sum([os.stat(name, dir_fd=rootfd).st_size
                end="")
    print("bytes in", len(files), "non-directory fi
    if 'CVS' in dirs:
        dirs.remove('CVS') # don't visit CVS direc
```

In the next example, walking the tree bottom-up is essential: `rmdir()` doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory na
# assuming there are no symbolic links.
# CAUTION: This is dangerous! For example, if top
# could delete all your disk files.
import os
for root, dirs, files, rootfd in os.fwalk(top, topd
    for name in files:
        os.unlink(name, dir_fd=rootfd)
```

```
for name in dirs:
    os.rmdir(name, dir_fd=rootfd)
```

Raises an [auditing event](#) `os.fwalk` with arguments `top`, `topdown`, `onerror`, `follow_symlinks`, `dir_fd`.

[Availability](#): Unix.

*New in version 3.3.*

*Changed in version 3.6*: Accepts a [path-like object](#).

*Changed in version 3.7*: Added support for [bytes](#) paths.

`os.memfd_create(name[, flags=os.MFD_CLOEXEC])`

Create an anonymous file and return a file descriptor that refers to it. *flags* must be one of the `os.MFD_*` constants available on the system (or a bitwise ORed combination of them). By default, the new file descriptor is [non-inheritable](#).

The name supplied in *name* is used as a filename and will be displayed as the target of the corresponding symbolic link in the directory `/proc/self/fd/`. The displayed name is always prefixed with `memfd:` and serves only for debugging purposes. Names do not affect the behavior of the file descriptor, and as such multiple files can have the same name without any side effects.

[Availability](#): Linux  $\geq 3.17$  with glibc  $\geq 2.27$ .

*New in version 3.8.*

`os.MFD_CLOEXEC`  
`os.MFD_ALLOW_SEALING`  
`os.MFD_HUGETLB`  
`os.MFD_HUGE_SHIFT`  
`os.MFD_HUGE_MASK`  
`os.MFD_HUGE_64KB`  
`os.MFD_HUGE_512KB`  
`os.MFD_HUGE_1MB`

os.MFD\_HUGE\_2MB  
os.MFD\_HUGE\_8MB  
os.MFD\_HUGE\_16MB  
os.MFD\_HUGE\_32MB  
os.MFD\_HUGE\_256MB  
os.MFD\_HUGE\_512MB  
os.MFD\_HUGE\_1GB  
os.MFD\_HUGE\_2GB  
os.MFD\_HUGE\_16GB

These flags can be passed to `memfd_create()`.

**Availability:** Linux  $\geq 3.17$  with glibc  $\geq 2.27$

The `MFD_HUGE*` flags are only available since Linux 4.14.

*New in version 3.8.*

`os.eventfd(initval [, flags = os.EFD_CLOEXEC])`

Create and return an event file descriptor. The file descriptors supports raw `read()` and `write()` with a buffer size of 8, `select()`, `poll()` and similar. See man page [eventfd\(2\)](#) for more information. By default, the new file descriptor is **non-inheritable**.

*initval* is the initial value of the event counter. The initial value must be an 32 bit unsigned integer. Please note that the initial value is limited to a 32 bit unsigned int although the event counter is an unsigned 64 bit integer with a maximum value of  $2^{64}-2$ .

*flags* can be constructed from `EFD_CLOEXEC`, `EFD_NONBLOCK`, and `EFD_SEMAPHORE`.

If `EFD_SEMAPHORE` is specified and the event counter is non-zero, `eventfd_read()` returns 1 and decrements the counter by one.

If `EFD_SEMAPHORE` is not specified and the event counter is non-zero, `eventfd_read()` returns the current event counter value and resets the counter to zero.

If the event counter is zero and `EFD_NONBLOCK` is not specified, `eventfd_read()` blocks.

`eventfd_write()` increments the event counter. Write blocks if the write operation would increment the counter to a value larger than  $2^{64}-2$ .

Example:

```
import os

# semaphore with start value '1'
fd = os.eventfd(1, os.EFD_SEMAPHORE | os.EFD_CLOEXEC)
try:
    # acquire semaphore
    v = os.eventfd_read(fd)
    try:
        do_work()
    finally:
        # release semaphore
        os.eventfd_write(fd, v)
finally:
    os.close(fd)
```

**Availability:** Linux  $\geq 2.6.27$  with glibc  $\geq 2.8$

*New in version 3.10.*

`os.eventfd_read(fd)`

Read value from an `eventfd()` file descriptor and return a 64 bit unsigned int. The function does not verify that `fd` is an `eventfd()`.

**Availability:** Linux  $\geq 2.6.27$

*New in version 3.10.*

`os.eventfd_write(fd, value)`

Add value to an `eventfd()` file descriptor. `value` must be a

64 bit unsigned int. The function does not verify that *fd* is an `eventfd()`.

*Availability:* Linux  $\geq$  2.6.27

*New in version 3.10.*

`os.EFD_CLOEXEC`

Set close-on-exec flag for new `eventfd()` file descriptor.

*Availability:* Linux  $\geq$  2.6.27

*New in version 3.10.*

`os.EFD_NONBLOCK`

Set `O_NONBLOCK` status flag for new `eventfd()` file descriptor.

*Availability:* Linux  $\geq$  2.6.27

*New in version 3.10.*

`os.EFD_SEMAPHORE`

Provide semaphore-like semantics for reads from a `eventfd()` file descriptor. On read the internal counter is decremented by one.

*Availability:* Linux  $\geq$  2.6.30

*New in version 3.10.*

## Linux extended attributes

*New in version 3.3.*

These functions are all available on Linux only.

`os.getxattr(path, attribute, *, follow_symlinks=True)`

Return the value of the extended filesystem attribute *attribute* for *path*. *attribute* can be bytes or str (directly or indirectly

through the [PathLike](#) interface). If it is str, it is encoded with the filesystem encoding.

This function can support [specifying a file descriptor](#) and [not following symlinks](#).

Raises an [auditing event](#) `os.getxattr` with arguments `path`, `attribute`.

*Changed in version 3.6:* Accepts a [path-like object](#) for *path* and *attribute*.

`os.listdir(path=None, *, follow_symlinks=True)`

Return a list of the extended filesystem attributes on *path*. The attributes in the list are represented as strings decoded with the filesystem encoding. If *path* is `None`, `listxattr()` will examine the current directory.

This function can support [specifying a file descriptor](#) and [not following symlinks](#).

Raises an [auditing event](#) `os.listdirxattr` with argument `path`.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.removexattr(path, attribute, *, follow_symlinks=True)`

Removes the extended filesystem attribute *attribute* from *path*. *attribute* should be bytes or str (directly or indirectly through the [PathLike](#) interface). If it is a string, it is encoded with the [filesystem encoding and error handler](#).

This function can support [specifying a file descriptor](#) and [not following symlinks](#).

Raises an [auditing event](#) `os.removexattr` with arguments `path`, `attribute`.

*Changed in version 3.6:* Accepts a [path-like object](#) for *path* and *attribute*.

`os.setxattr(path, attribute, value, flags=0, *, follow_symlinks=True)`

Set the extended filesystem attribute *attribute* on *path* to *value*. *attribute* must be a bytes or str with no embedded NULs (directly or indirectly through the [PathLike](#) interface). If it is a str, it is encoded with the [filesystem encoding and error handler](#). *flags* may be `XATTR_REPLACE` or `XATTR_CREATE`. If `XATTR_REPLACE` is given and the attribute does not exist, `ENODATA` will be raised. If `XATTR_CREATE` is given and the attribute already exists, the attribute will not be created and `EEXISTS` will be raised.

This function can support [specifying a file descriptor](#) and [not following symlinks](#).

### Note

A bug in Linux kernel versions less than 2.6.39 caused the *flags* argument to be ignored on some filesystems.

Raises an [auditing event](#) `os.setxattr` with arguments *path*, *attribute*, *value*, *flags*.

*Changed in version 3.6:* Accepts a [path-like object](#) for *path* and *attribute*.

`os.XATTR_SIZE_MAX`

The maximum size the value of an extended attribute can be. Currently, this is 64 KiB on Linux.

`os.XATTR_CREATE`

This is a possible value for the *flags* argument in [setxattr\(\)](#). It indicates the operation must create an attribute.

`os.XATTR_REPLACE`

This is a possible value for the *flags* argument in [setxattr\(\)](#). It indicates the operation must replace an existing attribute.

# Process Management

These functions may be used to create and manage processes.

The various **exec\*** functions take a list of arguments for the new program loaded into the process. In each case, the first of these arguments is passed to the new program as its own name rather than as an argument a user may have typed on a command line. For the C programmer, this is the `argv[0]` passed to a program's `main()`. For example, `os.execv('/bin/echo', ['foo', 'bar'])` will only print `bar` on standard output; `foo` will seem to be ignored.

## `os.abort()`

Generate a **SIGABRT** signal to the current process. On Unix, the default behavior is to produce a core dump; on Windows, the process immediately returns an exit code of 3. Be aware that calling this function will not call the Python signal handler registered for **SIGABRT** with `signal.signal()`.

## `os.add_dll_directory(path)`

Add a path to the DLL search path.

This search path is used when resolving dependencies for imported extension modules (the module itself is resolved through `sys.path`), and also by `ctypes`.

Remove the directory by calling `close()` on the returned object or using it in a `with` statement.

See the [Microsoft documentation](https://msdn.microsoft.com/44228cf2-6306-466c-8f16-f513cd3ba8b5) [https://msdn.microsoft.com/44228cf2-6306-466c-8f16-f513cd3ba8b5] for more information about how DLLs are loaded.

Raises an [auditing event](#) `os.add_dll_directory` with argument `path`.

[Availability](#): Windows.

*New in version 3.8:* Previous versions of CPython would

resolve DLLs using the default behavior for the current process. This led to inconsistencies, such as only sometimes searching **PATH** or the current working directory, and OS functions such as `AddDllDirectory` having no effect.

In 3.8, the two primary ways DLLs are loaded now explicitly override the process-wide behavior to ensure consistency. See the [porting notes](#) for information on updating libraries.

```
os.execl(path, arg0, arg1, ...)
os.execle(path, arg0, arg1, ..., env)
os.execlp(file, arg0, arg1, ...)
os.execlpe(file, arg0, arg1, ..., env)
os.execv(path, args)
os.execve(path, args, env)
os.execvp(file, args)
os.execvpe(file, args, env)
```

These functions all execute a new program, replacing the current process; they do not return. On Unix, the new executable is loaded into the current process, and will have the same process id as the caller. Errors will be reported as **OSError** exceptions.

The current process is replaced immediately. Open file objects and descriptors are not flushed, so if there may be data buffered on these open files, you should flush them using **`sys.stdout.flush()`** or **`os.fsync()`** before calling an **`exec*`** function.

The “l” and “v” variants of the **`exec*`** functions differ in how command-line arguments are passed. The “l” variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the **`execl*()`** functions. The “v” variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the **`args`** parameter. In either case, the arguments to the child process should start with the name of

the command being run, but this is not enforced.

The variants which include a “p” near the end (`exec1p()`, `exec1pe()`, `execvp()`, and `execvpe()`) will use the **PATH** environment variable to locate the program *file*. When the environment is being replaced (using one of the `exec*e` variants, discussed in the next paragraph), the new environment is used as the source of the **PATH** variable. The other variants, `exec1()`, `execle()`, `execv()`, and `execve()`, will not use the **PATH** variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For `execle()`, `exec1pe()`, `execve()`, and `execvpe()` (note that these all end in “e”), the *env* parameter must be a mapping which is used to define the environment variables for the new process (these are used instead of the current process’ environment); the functions `exec1()`, `exec1p()`, `execv()`, and `execvp()` all cause the new process to inherit the environment of the current process.

For `execve()` on some platforms, *path* may also be specified as an open file descriptor. This functionality may not be supported on your platform; you can check whether or not it is available using `os.supports_fd`. If it is unavailable, using it will raise a `NotImplementedError`.

Raises an `auditing event` `os.exec` with arguments `path`, `args`, `env`.

**Availability:** Unix, Windows, not Emscripten, not WASI.

*New in version 3.3:* Added support for specifying *path* as an open file descriptor for `execve()`.

*Changed in version 3.6:* Accepts a `path-like object`.

`os._exit(n)`

Exit the process with status *n*, without calling cleanup handlers, flushing stdio buffers, etc.

## Note

The standard way to exit is `sys.exit(n)`. `_exit()` should normally only be used in the child process after a `fork()`.

The following exit codes are defined and can be used with `_exit()`, although they are not required. These are typically used for system programs written in Python, such as a mail server's external command delivery program.

## Note

Some of these may not be available on all Unix platforms, since there is some variation. These constants are defined where they are defined by the underlying platform.

### os.EX\_OK

Exit code that means no error occurred. May be taken from the defined value of `EXIT_SUCCESS` on some platforms. Generally has a value of zero.

**Availability:** Unix, Windows.

### os.EX\_USAGE

Exit code that means the command was used incorrectly, such as when the wrong number of arguments are given.

**Availability:** Unix, not Emscripten, not WASI.

### os.EX\_DATAERR

Exit code that means the input data was incorrect.

**Availability:** Unix, not Emscripten, not WASI.

### os.EX\_NOINPUT

Exit code that means an input file did not exist or was not readable.

**Availability:** Unix, not Emscripten, not WASI.

`os.EX_NOUSER`

Exit code that means a specified user did not exist.

**Availability:** Unix, not Emscripten, not WASI.

`os.EX_NOHOST`

Exit code that means a specified host did not exist.

**Availability:** Unix, not Emscripten, not WASI.

`os.EX_UNAVAILABLE`

Exit code that means that a required service is unavailable.

**Availability:** Unix, not Emscripten, not WASI.

`os.EX_SOFTWARE`

Exit code that means an internal software error was detected.

**Availability:** Unix, not Emscripten, not WASI.

`os.EX_OSERR`

Exit code that means an operating system error was detected, such as the inability to fork or create a pipe.

**Availability:** Unix, not Emscripten, not WASI.

`os.EX_OSFILE`

Exit code that means some system file did not exist, could not be opened, or had some other kind of error.

**Availability:** Unix, not Emscripten, not WASI.

`os.EX_CANTCREAT`

Exit code that means a user specified output file could not be created.

**Availability:** Unix, not Emscripten, not WASI.

## os.EX\_IOERR

Exit code that means that an error occurred while doing I/O on some file.

**Availability:** Unix, not Emscripten, not WASI.

## os.EX\_TEMPFAIL

Exit code that means a temporary failure occurred. This indicates something that may not really be an error, such as a network connection that couldn't be made during a retryable operation.

**Availability:** Unix, not Emscripten, not WASI.

## os.EX\_PROTOCOL

Exit code that means that a protocol exchange was illegal, invalid, or not understood.

**Availability:** Unix, not Emscripten, not WASI.

## os.EX\_NOPERM

Exit code that means that there were insufficient permissions to perform the operation (but not intended for file system problems).

**Availability:** Unix, not Emscripten, not WASI.

## os.EX\_CONFIG

Exit code that means that some kind of configuration error occurred.

**Availability:** Unix, not Emscripten, not WASI.

## os.EX\_NOTFOUND

Exit code that means something like “an entry was not found”.

**Availability:** Unix, not Emscripten, not WASI.

## `os.fork()`

Fork a child process. Return `0` in the child and the child's process id in the parent. If an error occurs `OSError` is raised.

Note that some platforms including FreeBSD  $\leq 6.3$  and Cygwin have known issues when using `fork()` from a thread.

Raises an [auditing event](#) `os.fork` with no arguments.

*Changed in version 3.8:* Calling `fork()` in a subinterpreter is no longer supported (`RuntimeError` is raised).

### Warning

See [ssl](#) for applications that use the SSL module with `fork()`.

[Availability](#): Unix, not Emscripten, not WASI.

## `os.forkpty()`

Fork a child process, using a new pseudo-terminal as the child's controlling terminal. Return a pair of `(pid, fd)`, where `pid` is `0` in the child, the new child's process id in the parent, and `fd` is the file descriptor of the master end of the pseudo-terminal. For a more portable approach, use the [pty](#) module. If an error occurs `OSError` is raised.

Raises an [auditing event](#) `os.forkpty` with no arguments.

*Changed in version 3.8:* Calling `forkpty()` in a subinterpreter is no longer supported (`RuntimeError` is raised).

[Availability](#): Unix, not Emscripten, not WASI.

## `os.kill(pid, sig, /)`

Send signal `sig` to the process `pid`. Constants for the specific

signals available on the host platform are defined in the `signal` module.

Windows: The `signal.CTRL_C_EVENT` and `signal.CTRL_BREAK_EVENT` signals are special signals which can only be sent to console processes which share a common console window, e.g., some subprocesses. Any other value for `sig` will cause the process to be unconditionally killed by the `TerminateProcess` API, and the exit code will be set to `sig`. The Windows version of `kill()` additionally takes process handles to be killed.

See also `signal.pthread_kill()`.

Raises an `auditing event` `os.kill` with arguments `pid`, `sig`.

**Availability:** Unix, Windows, not Emscripten, not WASI.

*New in version 3.2:* Windows support.

`os.killpg(pgid, sig, /)`

Send the signal `sig` to the process group `pgid`.

Raises an `auditing event` `os.killpg` with arguments `pgid`, `sig`.

**Availability:** Unix, not Emscripten, not WASI.

`os.nice(increment, /)`

Add *increment* to the process's “niceness”. Return the new niceness.

**Availability:** Unix, not Emscripten, not WASI.

`os.pidfd_open(pid, flags=0)`

Return a file descriptor referring to the process `pid`. This descriptor can be used to perform process management without races and signals. The `flags` argument is provided for future extensions; no flag values are currently defined.

See the [pidfd\\_open\(2\)](#) man page for more details.

**Availability:** Linux  $\geq$  5.3

*New in version 3.9.*

`os.plock(op, /)`

Lock program segments into memory. The value of *op* (defined in `<sys/lock.h>`) determines which segments are locked.

**Availability:** Unix, not Emscripten, not WASI.

`os.popen(cmd, mode = 'r', buffering = - 1)`

Open a pipe to or from command *cmd*. The return value is an open file object connected to the pipe, which can be read or written depending on whether *mode* is 'r' (default) or 'w'. The *buffering* argument have the same meaning as the corresponding argument to the built-in [open\(\)](#) function. The returned file object reads or writes text strings rather than bytes.

The `close` method returns **None** if the subprocess exited successfully, or the subprocess's return code if there was an error. On POSIX systems, if the return code is positive it represents the return value of the process left-shifted by one byte. If the return code is negative, the process was terminated by the signal given by the negated value of the return code. (For example, the return value might be `- signal.SIGKILL` if the subprocess was killed.) On Windows systems, the return value contains the signed integer return code from the child process.

On Unix, [waitstatus\\_to\\_exitcode\(\)](#) can be used to convert the `close` method result (exit status) into an exit code if it is not **None**. On Windows, the `close` method result is directly the exit code (or **None**).

This is implemented using [subprocess.Popen](#); see that class's documentation for more powerful ways to manage and

communicate with subprocesses.

**Availability:** not Emscripten, not WASI.

### Note

The **Python UTF-8 Mode** affects encodings used for *cmd* and pipe contents.

**popen()** is a simple wrapper around **subprocess.Popen**. Use **subprocess.Popen** or **subprocess.run()** to control options like encodings.

```
os.posix_spawn(path, argv, env, *, file_actions=None,  
setpgroup=None, resetids=False, setsid=False, setsigmask=(),  
setsigdef=(), scheduler=None)
```

Wraps the **posix\_spawn()** C library API for use from Python.

Most users should use **subprocess.run()** instead of **posix\_spawn()**.

The positional-only arguments *path*, *args*, and *env* are similar to **execve()**.

The *path* parameter is the path to the executable file. The *path* should contain a directory. Use **posix\_spawnnp()** to pass an executable file without directory.

The *file\_actions* argument may be a sequence of tuples describing actions to take on specific file descriptors in the child process between the C library implementation's **fork()** and **exec()** steps. The first item in each tuple must be one of the three type indicator listed below describing the remaining tuple elements:

**os.POSIX\_SPAWN\_OPEN**

(**os.POSIX\_SPAWN\_OPEN**, *fd*, *path*, *flags*, *mode*)

Performs `os.dup2(os.open(path, flags, mode), fd)`.

`os.POSIX_SPAWN_CLOSE`

`(os.POSIX_SPAWN_CLOSE, fd)`

Performs `os.close(fd)`.

`os.POSIX_SPAWN_DUP2`

`(os.POSIX_SPAWN_DUP2, fd, new_fd)`

Performs `os.dup2(fd, new_fd)`.

These tuples correspond to the C library

`posix_spawn_file_actions_addopen()`,

`posix_spawn_file_actions_addclose()`, and

`posix_spawn_file_actions_adddup2()` API calls used to prepare for the `posix_spawn()` call itself.

The *setpgroup* argument will set the process group of the child to the value specified. If the value specified is 0, the child's process group ID will be made the same as its process ID. If the value of *setpgroup* is not set, the child will inherit the parent's process group ID. This argument corresponds to the C library `POSIX_SPAWN_SETPGROUP` flag.

If the *resetids* argument is `True` it will reset the effective UID and GID of the child to the real UID and GID of the parent process. If the argument is `False`, then the child retains the effective UID and GID of the parent. In either case, if the set-user-ID and set-group-ID permission bits are enabled on the executable file, their effect will override the setting of the effective UID and GID. This argument corresponds to the C library `POSIX_SPAWN_RESETIDS` flag.

If the *setsid* argument is `True`, it will create a new session ID for `posix_spawn`. *setsid* requires `POSIX_SPAWN_SETSID` or `POSIX_SPAWN_SETSID_NP` flag. Otherwise, `NotImplementedError` is raised.

The *setmask* argument will set the signal mask to the signal set specified. If the parameter is not used, then the child inherits the parent's signal mask. This argument corresponds to the C library **POSIX\_SPAWN\_SETSIGMASK** flag.

The *sigdef* argument will reset the disposition of all signals in the set specified. This argument corresponds to the C library **POSIX\_SPAWN\_SETSIGDEF** flag.

The *scheduler* argument must be a tuple containing the (optional) scheduler policy and an instance of **sched\_param** with the scheduler parameters. A value of `None` in the place of the scheduler policy indicates that is not being provided. This argument is a combination of the C library **POSIX\_SPAWN\_SETSCHEDPARAM** and **POSIX\_SPAWN\_SETSCHEDULER** flags.

Raises an **auditing event** `os.posix_spawn` with arguments `path`, `argv`, `env`.

*New in version 3.8.*

**Availability:** Unix, not Emscripten, not WASI.

```
os.posix_spawn(path, argv, env, *, file_actions=None,
setpgroup=None, resetids=False, setsid=False, setmask=(),
setsigdef=(), scheduler=None)
```

Wraps the **posix\_spawn()** C library API for use from Python.

Similar to **posix\_spawn()** except that the system searches for the *executable* file in the list of directories specified by the **PATH** environment variable (in the same way as for `execvp(3)`).

Raises an **auditing event** `os.posix_spawn` with arguments `path`, `argv`, `env`.

*New in version 3.8.*

**Availability:** POSIX, not Emscripten, not WASI.

See `posix_spawn()` documentation.

`os.register_at_fork(*, before=None, after_in_parent=None, after_in_child=None)`

Register callables to be executed when a new child process is forked using `os.fork()` or similar process cloning APIs. The parameters are optional and keyword-only. Each specifies a different call point.

- *before* is a function called before forking a child process.
- *after\_in\_parent* is a function called from the parent process after forking a child process.
- *after\_in\_child* is a function called from the child process.

These calls are only made if control is expected to return to the Python interpreter. A typical `subprocess` launch will not trigger them as the child is not going to re-enter the interpreter.

Functions registered for execution before forking are called in reverse registration order. Functions registered for execution after forking (either in the parent or in the child) are called in registration order.

Note that `fork()` calls made by third-party C code may not call those functions, unless it explicitly calls `PyOS_BeforeFork()`, `PyOS_AfterFork_Parent()` and `PyOS_AfterFork_Child()`.

There is no way to unregister a function.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.7.*

`os.spawnl(mode, path, ...)`

`os.spawnle(mode, path, ..., env)`

`os.spawnlp(mode, file, ...)`

```
os.spawnlpe(mode, file, ..., env)
os.spawnv(mode, path, args)
os.spawnve(mode, path, args, env)
os.spawnvp(mode, file, args)
os.spawnvpe(mode, file, args, env)
```

Execute the program *path* in a new process.

(Note that the [subprocess](#) module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using these functions. Check especially the [Replacing Older Functions with the subprocess Module](#) section.)

If *mode* is [P\\_NOWAIT](#), this function returns the process id of the new process; if *mode* is [P\\_WAIT](#), returns the process's exit code if it exits normally, or `-signal`, where *signal* is the signal that killed the process. On Windows, the process id will actually be the process handle, so can be used with the [waitpid\(\)](#) function.

Note on VxWorks, this function doesn't return `-signal` when the new process is killed. Instead it raises `OSError` exception.

The “l” and “v” variants of the [spawn\\*](#) functions differ in how command-line arguments are passed. The “l” variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the [spawnl\\*\(\)](#) functions. The “v” variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the *args* parameter. In either case, the arguments to the child process must start with the name of the command being run.

The variants which include a second “p” near the end ([spawnlp\(\)](#), [spawnlpe\(\)](#), [spawnvp\(\)](#), and [spawnvpe\(\)](#)) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the [spawn\\*e](#) variants, discussed in

the next paragraph), the new environment is used as the source of the **PATH** variable. The other variants, `spawnl()`, `spawnle()`, `spawnv()`, and `spawnve()`, will not use the **PATH** variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For `spawnle()`, `spawnlpe()`, `spawnve()`, and `spawnvpe()` (note that these all end in “e”), the *env* parameter must be a mapping which is used to define the environment variables for the new process (they are used instead of the current process’ environment); the functions `spawnl()`, `spawnlp()`, `spawnv()`, and `spawnvp()` all cause the new process to inherit the environment of the current process. Note that keys and values in the *env* dictionary must be strings; invalid keys or values will cause the function to fail, with a return value of 127.

As an example, the following calls to `spawnlp()` and `spawnvpe()` are equivalent:

```
import os
os.spawnlp(os.P_WAIT, 'cp', 'cp', 'index.html', '/d

L = ['cp', 'index.html', '/dev/null']
os.spawnvpe(os.P_WAIT, 'cp', L, os.environ)
```

Raises an [auditing event](#) `os.spawn` with arguments *mode*, *path*, *args*, *env*.

**Availability:** Unix, Windows, not Emscripten, not WASI.

`spawnlp()`, `spawnlpe()`, `spawnvp()` and `spawnvpe()` are not available on Windows. `spawnle()` and `spawnve()` are not thread-safe on Windows; we advise you to use the [subprocess](#) module instead.

*Changed in version 3.6:* Accepts a [path-like object](#).

`os.P_NOWAIT`  
`os.P_NOWAITO`

Possible values for the *mode* parameter to the `spawn*` family

of functions. If either of these values is given, the **spawn\*()** functions will return as soon as the new process has been created, with the process id as the return value.

**Availability:** Unix, Windows.

#### os.P\_WAIT

Possible value for the *mode* parameter to the **spawn\*** family of functions. If this is given as *mode*, the **spawn\*()** functions will not return until the new process has run to completion and will return the exit code of the process the run is successful, or `-signal` if a signal kills the process.

**Availability:** Unix, Windows.

#### os.P\_DETACH

#### os.P\_OVERLAY

Possible values for the *mode* parameter to the **spawn\*** family of functions. These are less portable than those listed above. **P\_DETACH** is similar to **P\_NOWAIT**, but the new process is detached from the console of the calling process. If **P\_OVERLAY** is used, the current process will be replaced; the **spawn\*** function will not return.

**Availability:** Windows.

#### os.startfile(*path* [, *operation*] [, *arguments*] [, *cwd*] [, *show\_cmd*])

Start a file with its associated application.

When *operation* is not specified or `'open'`, this acts like double-clicking the file in Windows Explorer, or giving the file name as an argument to the **start** command from the interactive command shell: the file is opened with whatever application (if any) its extension is associated.

When another *operation* is given, it must be a “command verb” that specifies what should be done with the file. Common verbs documented by Microsoft are `'print'` and `'edit'` (to be used on files) as well as `'explore'` and

'find' (to be used on directories).

When launching an application, specify *arguments* to be passed as a single string. This argument may have no effect when using this function to launch a document.

The default working directory is inherited, but may be overridden by the *cwd* argument. This should be an absolute path. A relative *path* will be resolved against this argument.

Use *show\_cmd* to override the default window style. Whether this has any effect will depend on the application being launched. Values are integers as supported by the Win32 **ShellExecute()** function.

**startfile()** returns as soon as the associated application is launched. There is no option to wait for the application to close, and no way to retrieve the application's exit status. The *path* parameter is relative to the current directory or *cwd*. If you want to use an absolute path, make sure the first character is not a slash (' / ') Use **pathlib** or the **os.path.normpath()** function to ensure that paths are properly encoded for Win32.

To reduce interpreter startup overhead, the Win32 **ShellExecute()** function is not resolved until this function is first called. If the function cannot be resolved, **NotImplementedError** will be raised.

Raises an **auditing event** `os.startfile` with arguments `path`, `operation`.

Raises an **auditing event** `os.startfile/2` with arguments `path`, `operation`, `arguments`, `cwd`, `show_cmd`.

**Availability:** Windows.

*Changed in version 3.10:* Added the *arguments*, *cwd* and *show\_cmd* arguments, and the `os.startfile/2` audit event.

`os.system(command)`

Execute the command (a string) in a subshell. This is implemented by calling the Standard C function `system()`, and has the same limitations. Changes to `sys.stdin`, etc. are not reflected in the environment of the executed command. If *command* generates any output, it will be sent to the interpreter standard output stream. The C standard does not specify the meaning of the return value of the C function, so the return value of the Python function is system-dependent.

On Unix, the return value is the exit status of the process encoded in the format specified for `wait()`.

On Windows, the return value is that returned by the system shell after running *command*. The shell is given by the Windows environment variable `COMSPEC`: it is usually `cmd.exe`, which returns the exit status of the command run; on systems using a non-native shell, consult your shell documentation.

The `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using this function. See the [Replacing Older Functions with the subprocess Module](#) section in the `subprocess` documentation for some helpful recipes.

On Unix, `waitstatus_to_exitcode()` can be used to convert the result (exit status) into an exit code. On Windows, the result is directly the exit code.

Raises an [auditing event](#) `os.system` with argument *command*.

**Availability:** Unix, Windows, not Emscripten, not WASI.

## `os.times()`

Returns the current global process times. The return value is an object with five attributes:

- **user** - user time

- **system** - system time
- **children\_user** - user time of all child processes
- **children\_system** - system time of all child processes
- **elapsed** - elapsed real time since a fixed point in the past

For backwards compatibility, this object also behaves like a five-tuple containing **user**, **system**, **children\_user**, **children\_system**, and **elapsed** in that order.

See the Unix manual page [times\(2\)](https://man.freebsd.org/cgi/man.cgi?time(3)) and [times\(3\)](https://man.freebsd.org/cgi/man.cgi?time(3)) [https://man.freebsd.org/cgi/man.cgi?time(3)] manual page on Unix or [the GetProcessTimes MSDN](https://docs.microsoft.com/windows/win32/api/processthreadsapi/nf-processthreadsapi-getprocesstimes) [https://docs.microsoft.com/windows/win32/api/processthreadsapi/nf-processthreadsapi-getprocesstimes] on Windows. On Windows, only **user** and **system** are known; the other attributes are zero.

**Availability:** Unix, Windows.

*Changed in version 3.3:* Return type changed from a tuple to a tuple-like object with named attributes.

## os.wait()

Wait for completion of a child process, and return a tuple containing its pid and exit status indication: a 16-bit number, whose low byte is the signal number that killed the process, and whose high byte is the exit status (if the signal number is zero); the high bit of the low byte is set if a core file was produced.

If there are no children that could be waited for, **ChildProcessError** is raised.

[waitstatus\\_to\\_exitcode\(\)](#) can be used to convert the exit status into an exit code.

**Availability:** Unix, not Emscripten, not WASI.

## See also

The other **wait\*()** functions documented below can be

used to wait for the completion of a specific child process and have more options. `waitpid()` is the only one also available on Windows.

`os.waitid(idtype, id, options, /)`

Wait for the completion of a child process.

*idtype* can be `P_PID`, `P_PGID`, `P_ALL`, or (on Linux) `P_PIDFD`. The interpretation of *id* depends on it; see their individual descriptions.

*options* is an OR combination of flags. At least one of `WEXITED`, `WSTOPPED` or `WCONTINUED` is required; `WNOHANG` and `WNOWAIT` are additional optional flags.

The return value is an object representing the data contained in the `siginfo_t` structure with the following attributes:

- `si_pid` (process ID)
- `si_uid` (real user ID of the child)
- `si_signo` (always `SIGCHLD`)
- `si_status` (the exit status or signal number, depending on `si_code`)
- `si_code` (see `CLD_EXITED` for possible values)

If `WNOHANG` is specified and there are no matching children in the requested state, `None` is returned. Otherwise, if there are no matching children that could be waited for, `ChildProcessError` is raised.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3.*

`os.waitpid(pid, options, /)`

The details of this function differ on Unix and Windows.

On Unix: Wait for completion of a child process given by process id *pid*, and return a tuple containing its process id and

exit status indication (encoded as for `wait()`). The semantics of the call are affected by the value of the integer *options*, which should be 0 for normal operation.

If *pid* is greater than 0, `waitpid()` requests status information for that specific process. If *pid* is 0, the request is for the status of any child in the process group of the current process. If *pid* is -1, the request pertains to any child of the current process. If *pid* is less than -1, status is requested for any process in the process group -*pid* (the absolute value of *pid*).

*options* is an OR combination of flags. If it contains `WNOHANG` and there are no matching children in the requested state, (0, 0) is returned. Otherwise, if there are no matching children that could be waited for, `ChildProcessError` is raised. Other options that can be used are `WUNTRACED` and `WCONTINUED`.

On Windows: Wait for completion of a process given by process handle *pid*, and return a tuple containing *pid*, and its exit status shifted left by 8 bits (shifting makes cross-platform use of the function easier). A *pid* less than or equal to 0 has no special meaning on Windows, and raises an exception. The value of integer *options* has no effect. *pid* can refer to any process whose id is known, not necessarily a child process. The `spawn*` functions called with `P_NOWAIT` return suitable process handles.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exit code.

**Availability:** Unix, Windows, not Emscripten, not WASI.

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](https://peps.python.org/pep-0475/) [https://peps.python.org/pep-0475/] for the rationale).

`os.wait3(options)`

Similar to `waitpid()`, except no process id argument is given and a 3-element tuple containing the child's process id, exit status indication, and resource usage information is returned. Refer to `resource.getrusage()` for details on resource usage information. The `options` argument is the same as that provided to `waitpid()` and `wait4()`.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exitcode.

**Availability:** Unix, not Emscripten, not WASI.

`os.wait4(pid, options)`

Similar to `waitpid()`, except a 3-element tuple, containing the child's process id, exit status indication, and resource usage information is returned. Refer to `resource.getrusage()` for details on resource usage information. The arguments to `wait4()` are the same as those provided to `waitpid()`.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exitcode.

**Availability:** Unix, not Emscripten, not WASI.

`os.P_PID`

`os.P_PGID`

`os.P_ALL`

`os.P_PIDFD`

These are the possible values for `idtype` in `waitid()`. They affect how `id` is interpreted:

- **P\_PID** - wait for the child whose PID is `id`.
- **P\_PGID** - wait for any child whose progress group ID is `id`.
- **P\_ALL** - wait for any child; `id` is ignored.
- **P\_PIDFD** - wait for the child identified by the file descriptor `id` (a process file descriptor created with `pidfd_open()`).

**Availability:** Unix, not Emscripten, not WASI.

### Note

**P\_PIDFD** is only available on Linux  $\geq 5.4$ .

*New in version 3.3.*

*New in version 3.9:* The **P\_PIDFD** constant.

## os.WCONTINUED

This *options* flag for **waitpid()**, **wait3()**, **wait4()**, and **waitid()** causes child processes to be reported if they have been continued from a job control stop since they were last reported.

**Availability:** Unix, not Emscripten, not WASI.

## os.WEXITED

This *options* flag for **waitid()** causes child processes that have terminated to be reported.

The other `wait*` functions always report children that have terminated, so this option is not available for them.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3.*

## os.WSTOPPED

This *options* flag for **waitid()** causes child processes that have been stopped by the delivery of a signal to be reported.

This option is not available for the other `wait*` functions.

**Availability:** Unix, not Emscripten, not WASI.

*New in version 3.3.*

## os.WUNTRACED

This *options* flag for `waitpid()`, `wait3()`, and `wait4()` causes child processes to also be reported if they have been stopped but their current state has not been reported since they were stopped.

This option is not available for `waitid()`.

*Availability:* Unix, not Emscripten, not WASI.

## os.WNOHANG

This *options* flag causes `waitpid()`, `wait3()`, `wait4()`, and `waitid()` to return right away if no child process status is available immediately.

*Availability:* Unix, not Emscripten, not WASI.

## os.WNOWAIT

This *options* flag causes `waitid()` to leave the child in a waitable state, so that a later `wait*()` call can be used to retrieve the child status information again.

This option is not available for the other `wait*` functions.

*Availability:* Unix, not Emscripten, not WASI.

## os.CLD\_EXITED

## os.CLD\_KILLED

## os.CLD\_DUMPED

## os.CLD\_TRAPPED

## os.CLD\_STOPPED

## os.CLD\_CONTINUED

These are the possible values for `si_code` in the result returned by `waitid()`.

*Availability:* Unix, not Emscripten, not WASI.

*New in version 3.3.*

*Changed in version 3.9:* Added `CLD_KILLED` and `CLD_STOPPED` values.

`os.waitstatus_to_exitcode(status)`

Convert a wait status to an exit code.

On Unix:

- If the process exited normally (if `WIFEXITED(status)` is true), return the process exit status (return `WEXITSTATUS(status)`): result greater than or equal to 0.
- If the process was terminated by a signal (if `WIFSIGNALED(status)` is true), return `-signum` where *signum* is the number of the signal that caused the process to terminate (return `-WTERMSIG(status)`): result less than 0.
- Otherwise, raise a **ValueError**.

On Windows, return *status* shifted right by 8 bits.

On Unix, if the process is being traced or if `waitpid()` was called with **WUNTRACED** option, the caller must first check if `WIFSTOPPED(status)` is true. This function must not be called if `WIFSTOPPED(status)` is true.

**See also**

**WIFEXITED()**, **WEXITSTATUS()**, **WIFSIGNALED()**, **WTERMSIG()**, **WIFSTOPPED()**, **WSTOPSIG()** functions.

**Availability:** Unix, Windows, not Emscripten, not WASI.

*New in version 3.9.*

The following functions take a process status code as returned by **system()**, **wait()**, or **waitpid()** as a parameter. They may be used to determine the disposition of a process.

`os.WCOREDUMP(status, /)`

Return `True` if a core dump was generated for the process, otherwise return `False`.

This function should be employed only if `WIFSIGNALED()` is true.

**Availability:** Unix, not Emscripten, not WASI.

#### `os.WIFCONTINUED(status)`

Return `True` if a stopped child has been resumed by delivery of `SIGCONT` (if the process has been continued from a job control stop), otherwise return `False`.

See `WCONTINUED` option.

**Availability:** Unix, not Emscripten, not WASI.

#### `os.WIFSTOPPED(status)`

Return `True` if the process was stopped by delivery of a signal, otherwise return `False`.

`WIFSTOPPED()` only returns `True` if the `waitpid()` call was done using `WUNTRACED` option or when the process is being traced (see `ptrace(2)`).

**Availability:** Unix, not Emscripten, not WASI.

#### `os.WIFSIGNALED(status)`

Return `True` if the process was terminated by a signal, otherwise return `False`.

**Availability:** Unix, not Emscripten, not WASI.

#### `os.WIFEXITED(status)`

Return `True` if the process exited terminated normally, that is, by calling `exit()` or `_exit()`, or by returning from `main()`; otherwise return `False`.

**Availability:** Unix, not Emscripten, not WASI.

#### `os.WEXITSTATUS(status)`

Return the process exit status.

This function should be employed only if `WIFEXITED()` is true.

**Availability:** Unix, not Emscripten, not WASI.

`os.WSTOPSIG(status)`

Return the signal which caused the process to stop.

This function should be employed only if `WIFSTOPPED()` is true.

**Availability:** Unix, not Emscripten, not WASI.

`os.WTERMSIG(status)`

Return the number of the signal that caused the process to terminate.

This function should be employed only if `WIFSIGNALED()` is true.

**Availability:** Unix, not Emscripten, not WASI.

## Interface to the scheduler

These functions control how a process is allocated CPU time by the operating system. They are only available on some Unix platforms. For more detailed information, consult your Unix manpages.

*New in version 3.3.*

The following scheduling policies are exposed if they are supported by the operating system.

`os.SCHED_OTHER`

The default scheduling policy.

`os.SCHED_BATCH`

Scheduling policy for CPU-intensive processes that tries to preserve interactivity on the rest of the computer.

`os.SCHED_IDLE`

Scheduling policy for extremely low priority background tasks.

`os.SCHED_SPORADIC`

Scheduling policy for sporadic server programs.

`os.SCHED_FIFO`

A First In First Out scheduling policy.

`os.SCHED_RR`

A round-robin scheduling policy.

`os.SCHED_RESET_ON_FORK`

This flag can be OR'ed with any other scheduling policy. When a process with this flag set forks, its child's scheduling policy and priority are reset to the default.

`class os.sched_param(sched_priority)`

This class represents tunable scheduling parameters used in `sched_setparam()`, `sched_setscheduler()`, and `sched_getparam()`. It is immutable.

At the moment, there is only one possible parameter:

`sched_priority`

The scheduling priority for a scheduling policy.

`os.sched_get_priority_min(policy)`

Get the minimum priority value for *policy*. *policy* is one of the scheduling policy constants above.

`os.sched_get_priority_max(policy)`

Get the maximum priority value for *policy*. *policy* is one of the

scheduling policy constants above.

`os.sched_setscheduler(pid, policy, param, /)`

Set the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. *policy* is one of the scheduling policy constants above. *param* is a `sched_param` instance.

`os.sched_getscheduler(pid, /)`

Return the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. The result is one of the scheduling policy constants above.

`os.sched_setparam(pid, param, /)`

Set the scheduling parameters for the process with PID *pid*. A *pid* of 0 means the calling process. *param* is a `sched_param` instance.

`os.sched_getparam(pid, /)`

Return the scheduling parameters as a `sched_param` instance for the process with PID *pid*. A *pid* of 0 means the calling process.

`os.sched_rr_get_interval(pid, /)`

Return the round-robin quantum in seconds for the process with PID *pid*. A *pid* of 0 means the calling process.

`os.sched_yield()`

Voluntarily relinquish the CPU.

`os.sched_setaffinity(pid, mask, /)`

Restrict the process with PID *pid* (or the current process if zero) to a set of CPUs. *mask* is an iterable of integers representing the set of CPUs to which the process should be restricted.

`os.sched_getaffinity(pid, /)`

Return the set of CPUs the process with PID *pid* (or the current process if zero) is restricted to.

## Miscellaneous System Information

`os.confstr(name, /)`

Return string-valued system configuration values. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given as the keys of the `confstr_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If the configuration value specified by *name* isn't defined, `None` is returned.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `confstr_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

**Availability:** Unix.

`os.confstr_names`

Dictionary mapping names accepted by `confstr()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

**Availability:** Unix.

`os.cpu_count()`

Return the number of CPUs in the system. Returns `None` if undetermined.

This number is not equivalent to the number of CPUs the current process can use. The number of usable CPUs can be obtained with `len(os.sched_getaffinity(0))`

*New in version 3.4.*

`os.getloadavg()`

Return the number of processes in the system run queue averaged over the last 1, 5, and 15 minutes or raises **OSError** if the load average was unobtainable.

**Availability:** Unix.

`os.sysconf(name, /)`

Return integer-valued system configuration values. If the configuration value specified by *name* isn't defined, `-1` is returned. The comments regarding the *name* parameter for **confstr()** apply here as well; the dictionary that provides information on the known names is given by `sysconf_names`.

**Availability:** Unix.

`os.sysconf_names`

Dictionary mapping names accepted by **sysconf()** to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

**Availability:** Unix.

*Changed in version 3.11:* Add `'SC_MINSIGSTKSZ'` name.

The following data values are used to support path manipulation operations. These are defined for all platforms.

Higher-level operations on pathnames are defined in the **os.path** module.

## os.curdir

The constant string used by the operating system to refer to the current directory. This is `'.'` for Windows and POSIX. Also available via `os.path`.

## os.pardir

The constant string used by the operating system to refer to the parent directory. This is `'..'` for Windows and POSIX. Also available via `os.path`.

## os.sep

The character used by the operating system to separate pathname components. This is `'/'` for POSIX and `'\\'` for Windows. Note that knowing this is not sufficient to be able to parse or concatenate pathnames — use `os.path.split()` and `os.path.join()` — but it is occasionally useful. Also available via `os.path`.

## os.altsep

An alternative character used by the operating system to separate pathname components, or `None` if only one separator character exists. This is set to `'/'` on Windows systems where `sep` is a backslash. Also available via `os.path`.

## os.extsep

The character which separates the base filename from the extension; for example, the `'.'` in `os.py`. Also available via `os.path`.

## os.pathsep

The character conventionally used by the operating system to separate search path components (as in `PATH`), such as `':'` for POSIX or  `';'`  for Windows. Also available via `os.path`.

## os.defpath

The default search path used by `exec*p*` and `spawn*p*` if the environment doesn't have a `'PATH'` key. Also available

via [os.path](#).

### `os.linesep`

The string used to separate (or, rather, terminate) lines on the current platform. This may be a single character, such as `'\n'` for POSIX, or multiple characters, for example, `'\r\n'` for Windows. Do not use `os.linesep` as a line terminator when writing files opened in text mode (the default); use a single `'\n'` instead, on all platforms.

### `os.devnull`

The file path of the null device. For example: `'/dev/null'` for POSIX, `'nul'` for Windows. Also available via [os.path](#).

### `os.RTLD_LAZY`

### `os.RTLD_NOW`

### `os.RTLD_GLOBAL`

### `os.RTLD_LOCAL`

### `os.RTLD_NODELETE`

### `os.RTLD_NOLOAD`

### `os.RTLD_DEEPBIND`

Flags for use with the [setdlopenflags\(\)](#) and [getdlopenflags\(\)](#) functions. See the Unix manual page [dlopen\(3\)](#) for what the different flags mean.

*New in version 3.3.*

## Random numbers

### `os.getrandom(size, flags=0)`

Get up to *size* random bytes. The function can return less bytes than requested.

These bytes can be used to seed user-space random number generators or for cryptographic purposes.

`getrandom()` relies on entropy gathered from device drivers

and other sources of environmental noise. Unnecessarily reading large quantities of data will have a negative impact on other users of the `/dev/random` and `/dev/urandom` devices.

The `flags` argument is a bit mask that can contain zero or more of the following values ORed together:

`os.GRND_RANDOM` and `GRND_NONBLOCK`.

See also the [Linux `getrandom\(\)` manual page](https://man7.org/linux/man-pages/man2/getrandom.2.html) [https://man7.org/linux/man-pages/man2/getrandom.2.html].

**Availability:** Linux  $\geq$  3.17.

*New in version 3.6.*

`os.urandom(size, /)`

Return a bytestring of *size* random bytes suitable for cryptographic use.

This function returns random bytes from an OS-specific randomness source. The returned data should be unpredictable enough for cryptographic applications, though its exact quality depends on the OS implementation.

On Linux, if the `getrandom()` syscall is available, it is used in blocking mode: block until the system `urandom` entropy pool is initialized (128 bits of entropy are collected by the kernel). See the [PEP 524](https://peps.python.org/pep-0524/) [https://peps.python.org/pep-0524/] for the rationale. On Linux, the `getrandom()` function can be used to get random bytes in non-blocking mode (using the `GRND_NONBLOCK` flag) or to poll until the system `urandom` entropy pool is initialized.

On a Unix-like system, random bytes are read from the `/dev/urandom` device. If the `/dev/urandom` device is not available or not readable, the `NotImplementedError` exception is raised.

On Windows, it will use `BCryptGenRandom()`.

## See also

The `secrets` module provides higher level functions. For an easy-to-use interface to the random number generator provided by your platform, please see `random.SystemRandom`.

*Changed in version 3.6.0:* On Linux, `getrandom()` is now used in blocking mode to increase the security.

*Changed in version 3.5.2:* On Linux, if the `getrandom()` syscall blocks (the urandom entropy pool is not initialized yet), fall back on reading `/dev/urandom`.

*Changed in version 3.5:* On Linux 3.17 and newer, the `getrandom()` syscall is now used when available. On OpenBSD 5.6 and newer, the C `getentropy()` function is now used. These functions avoid the usage of an internal file descriptor.

*Changed in version 3.11:* On Windows, `BCryptGenRandom()` is used instead of `CryptGenRandom()` which is deprecated.

## os.GRND\_NONBLOCK

By default, when reading from `/dev/random`, `getrandom()` blocks if no random bytes are available, and when reading from `/dev/urandom`, it blocks if the entropy pool has not yet been initialized.

If the `GRND_NONBLOCK` flag is set, then `getrandom()` does not block in these cases, but instead immediately raises `BlockingIOError`.

*New in version 3.6.*

## os.GRND\_RANDOM

If this bit is set, then random bytes are drawn from the `/dev/random` pool instead of the `/dev/urandom` pool.

*New in version 3.6.*

# io — Core tools for working with streams

Source code: [Lib/io.py](https://github.com/python/cpython/tree/3.11/Lib/io.py) [https://github.com/python/cpython/tree/3.11/Lib/io.py]

---

## Overview

The `io` module provides Python's main facilities for dealing with various types of I/O. There are three main types of I/O: *text I/O*, *binary I/O* and *raw I/O*. These are generic categories, and various backing stores can be used for each of them. A concrete object belonging to any of these categories is called a [file object](#). Other common terms are *stream* and *file-like object*.

Independent of its category, each concrete stream object will also have various capabilities: it can be read-only, write-only, or read-write. It can also allow arbitrary random access (seeking forwards or backwards to any location), or only sequential access (for example in the case of a socket or pipe).

All streams are careful about the type of data you give to them. For example giving a `str` object to the `write()` method of a binary stream will raise a `TypeError`. So will giving a `bytes` object to the `write()` method of a text stream.

*Changed in version 3.3:* Operations that used to raise `IOError` now raise `OSError`, since `IOError` is now an alias of `OSError`.

## Text I/O

Text I/O expects and produces `str` objects. This means that whenever the backing store is natively made of bytes (such as in the case of a file), encoding and decoding of data is made transparently

as well as optional translation of platform-specific newline characters.

The easiest way to create a text stream is with `open()`, optionally specifying an encoding:

```
f = open("myfile.txt", "r", encoding="utf-8")
```

In-memory text streams are also available as `StringIO` objects:

```
f = io.StringIO("some initial text data")
```

The text stream API is described in detail in the documentation of `TextIOBase`.

## Binary I/O

Binary I/O (also called *buffered I/O*) expects `bytes-like objects` and produces `bytes` objects. No encoding, decoding, or newline translation is performed. This category of streams can be used for all kinds of non-text data, and also when manual control over the handling of text data is desired.

The easiest way to create a binary stream is with `open()` with 'b' in the mode string:

```
f = open("myfile.jpg", "rb")
```

In-memory binary streams are also available as `BytesIO` objects:

```
f = io.BytesIO(b"some initial binary data: \x00\x01")
```

The binary stream API is described in detail in the docs of `BufferedIOBase`.

Other library modules may provide additional ways to create text or binary streams. See `socket.socket.makefile()` for example.

## Raw I/O

Raw I/O (also called *unbuffered I/O*) is generally used as a low-level

building-block for binary and text streams; it is rarely useful to directly manipulate a raw stream from user code. Nevertheless, you can create a raw stream by opening a file in binary mode with buffering disabled:

```
f = open("myfile.jpg", "rb", buffering=0)
```

The raw stream API is described in detail in the docs of [RawIOBase](#).

## Text Encoding

The default encoding of [TextIOWrapper](#) and [open\(\)](#) is locale-specific ([locale.getencoding\(\)](#)).

However, many developers forget to specify the encoding when opening text files encoded in UTF-8 (e.g. JSON, TOML, Markdown, etc...) since most Unix platforms use UTF-8 locale by default. This causes bugs because the locale encoding is not UTF-8 for most Windows users. For example:

```
# May not work on Windows when non-ASCII characters in t
with open("README.md") as f:
    long_description = f.read()
```

Accordingly, it is highly recommended that you specify the encoding explicitly when opening text files. If you want to use UTF-8, pass `encoding="utf-8"`. To use the current locale encoding, `encoding="locale"` is supported since Python 3.10.

### See also

#### Python UTF-8 Mode

Python UTF-8 Mode can be used to change the default encoding to UTF-8 from locale-specific encoding.

**PEP 686** [<https://peps.python.org/pep-0686/>]

Python 3.15 will make [Python UTF-8 Mode](#) default.

## Opt-in EncodingWarning

*New in version 3.10:* See [PEP 597](https://peps.python.org/pep-0597/) [https://peps.python.org/pep-0597/] for more details.

To find where the default locale encoding is used, you can enable the `-X warn_default_encoding` command line option or set the `PYTHONWARNDEFAULTENCODING` environment variable, which will emit an `EncodingWarning` when the default encoding is used.

If you are providing an API that uses `open()` or `TextIOWrapper` and passes `encoding=None` as a parameter, you can use `text_encoding()` so that callers of the API will emit an `EncodingWarning` if they don't pass an `encoding`. However, please consider using UTF-8 by default (i.e. `encoding="utf-8"`) for new APIs.

## High-level Module Interface

### `io.DEFAULT_BUFFER_SIZE`

An int containing the default buffer size used by the module's buffered I/O classes. `open()` uses the file's `blksize` (as obtained by `os.stat()`) if possible.

`io.open(file, mode='r', buffering=-1, encoding=None, errors=None, newline=None, closefd=True, opener=None)`

This is an alias for the builtin `open()` function.

This function raises an `auditing event` `open` with arguments `path`, `mode` and `flags`. The `mode` and `flags` arguments may have been modified or inferred from the original call.

### `io.open_code(path)`

Opens the provided file with mode `'rb'`. This function should be used when the intent is to treat the contents as executable code.

path should be a `str` and an absolute path.

The behavior of this function may be overridden by an earlier call to the `PyFile_SetOpenCodeHook()`. However, assuming that path is a `str` and an absolute path, `open_code(path)` should always behave the same as `open(path, 'rb')`. Overriding the behavior is intended for additional validation or preprocessing of the file.

*New in version 3.8.*

`io.text_encoding(encoding, stacklevel=2, /)`

This is a helper function for callables that use `open()` or `TextIOWrapper` and have an `encoding=None` parameter.

This function returns `encoding` if it is not `None`. Otherwise, it returns `"locale"` or `"utf-8"` depending on [UTF-8 Mode](#).

This function emits an `EncodingWarning` if `sys.flags.warn_default_encoding` is true and `encoding` is `None`. `stacklevel` specifies where the warning is emitted. For example:

```
def read_text(path, encoding=None):
    encoding = io.text_encoding(encoding) # stackl
    with open(path, encoding) as f:
        return f.read()
```

In this example, an `EncodingWarning` is emitted for the caller of `read_text()`.

See [Text Encoding](#) for more information.

*New in version 3.10.*

*Changed in version 3.11:* `text_encoding()` returns `"utf-8"` when UTF-8 mode is enabled and `encoding` is `None`.

*exception* `io.BlockingIOError`

This is a compatibility alias for the builtin

`BlockingIOError` exception.

exception `io.UnsupportedOperation`

An exception inheriting `OSError` and `ValueError` that is raised when an unsupported operation is called on a stream.

See also

`sys`

contains the standard IO streams: `sys.stdin`, `sys.stdout`, and `sys.stderr`.

## Class hierarchy

The implementation of I/O streams is organized as a hierarchy of classes. First [abstract base classes](#) (ABCs), which are used to specify the various categories of streams, then concrete classes providing the standard stream implementations.

### Note

The abstract base classes also provide default implementations of some methods in order to help implementation of concrete stream classes. For example, `BufferedIOBase` provides unoptimized implementations of `readinto()` and `readline()`.

At the top of the I/O hierarchy is the abstract base class `IOBase`. It defines the basic interface to a stream. Note, however, that there is no separation between reading and writing to streams; implementations are allowed to raise `UnsupportedOperation` if they do not support a given operation.

The `RawIOBase` ABC extends `IOBase`. It deals with the reading and writing of bytes to a stream. `FileIO` subclasses `RawIOBase`

to provide an interface to files in the machine's file system.

The `BufferedIOBase` ABC extends `IOBase`. It deals with buffering on a raw binary stream (`RawIOBase`). Its subclasses, `BufferedWriter`, `BufferedReader`, and `BufferedRWPair` buffer raw binary streams that are writable, readable, and both readable and writable, respectively. `BufferedRandom` provides a buffered interface to seekable streams. Another `BufferedIOBase` subclass, `BytesIO`, is a stream of in-memory bytes.

The `TextIOBase` ABC extends `IOBase`. It deals with streams whose bytes represent text, and handles encoding and decoding to and from strings. `TextIOWrapper`, which extends `TextIOBase`, is a buffered text interface to a buffered raw stream (`BufferedIOBase`). Finally, `StringIO` is an in-memory stream for text.

Argument names are not part of the specification, and only the arguments of `open()` are intended to be used as keyword arguments.

The following table summarizes the ABCs provided by the `io` module:

## Minimal Methods and Properties

```
close, check, and enterate, __exit__, flush, isatty,  
__iter__, __next__, readable, readline, readlines,  
seekable, tell, writable, and writelines
```

```

Inherited SQLBase methods, read, and readall

```

```

Inherited methods: read, readinto, readinto1

```

```

InheritedBase, see methods, and writing errors, and
newlines

```

## I/O Base Classes

```
class io.IOBase
```

The abstract base class for all I/O classes.

This class provides empty abstract implementations for many methods that derived classes can override selectively; the default implementations represent a file that cannot be read,

written or seeked.

Even though `IOBase` does not declare `read()` or `write()` because their signatures will vary, implementations and clients should consider those methods part of the interface. Also, implementations may raise a `ValueError` (or `UnsupportedOperation`) when operations they do not support are called.

The basic type used for binary data read from or written to a file is `bytes`. Other `bytes-like objects` are accepted as method arguments too. Text I/O classes work with `str` data.

Note that calling any method (even inquiries) on a closed stream is undefined. Implementations may raise `ValueError` in this case.

`IOBase` (and its subclasses) supports the iterator protocol, meaning that an `IOBase` object can be iterated over yielding the lines in a stream. Lines are defined slightly differently depending on whether the stream is a binary stream (yielding bytes), or a text stream (yielding character strings). See `readline()` below.

`IOBase` is also a context manager and therefore supports the `with` statement. In this example, *file* is closed after the `with` statement's suite is finished—even if an exception occurs:

```
with open('spam.txt', 'w') as file:
    file.write('Spam and eggs!')
```

`IOBase` provides these data attributes and methods:

`close()`

Flush and close this stream. This method has no effect if the file is already closed. Once the file is closed, any operation on the file (e.g. reading or writing) will raise a `ValueError`.

As a convenience, it is allowed to call this method more than once; only the first call, however, will have an

effect.

`closed`

`True` if the stream is closed.

`fileno()`

Return the underlying file descriptor (an integer) of the stream if it exists. An **`OSError`** is raised if the IO object does not use a file descriptor.

`flush()`

Flush the write buffers of the stream if applicable. This does nothing for read-only and non-blocking streams.

`isatty()`

Return `True` if the stream is interactive (i.e., connected to a terminal/tty device).

`readable()`

Return `True` if the stream can be read from. If `False`, **`read()`** will raise **`OSError`**.

`readline(size = -1, /)`

Read and return one line from the stream. If *size* is specified, at most *size* bytes will be read.

The line terminator is always `b'\n'` for binary files; for text files, the *newline* argument to **`open()`** can be used to select the line terminator(s) recognized.

`readlines(hint = -1, /)`

Read and return a list of lines from the stream. *hint* can be specified to control the number of lines read: no more lines will be read if the total size (in bytes/characters) of all lines so far exceeds *hint*.

*hint* values of 0 or less, as well as `None`, are treated as

no hint.

Note that it's already possible to iterate on file objects using `for line in file: ...` without calling `file.readlines()`.

`seek(offset, whence = SEEK_SET, /)`

Change the stream position to the given byte *offset*. *offset* is interpreted relative to the position indicated by *whence*. The default value for *whence* is **SEEK\_SET**. Values for *whence* are:

- **SEEK\_SET** or 0 – start of the stream (the default); *offset* should be zero or positive
- **SEEK\_CUR** or 1 – current stream position; *offset* may be negative
- **SEEK\_END** or 2 – end of the stream; *offset* is usually negative

Return the new absolute position.

*New in version 3.1:* The `SEEK_*` constants.

*New in version 3.3:* Some operating systems could support additional values, like `os.SEEK_HOLE` or `os.SEEK_DATA`. The valid values for a file could depend on it being open in text or binary mode.

`seekable()`

Return `True` if the stream supports random access. If `False`, `seek()`, `tell()` and `truncate()` will raise **IOError**.

`tell()`

Return the current stream position.

`truncate(size = None, /)`

Resize the stream to the given *size* in bytes (or the current position if *size* is not specified). The current

stream position isn't changed. This resizing can extend or reduce the current file size. In case of extension, the contents of the new file area depend on the platform (on most systems, additional bytes are zero-filled). The new file size is returned.

*Changed in version 3.5:* Windows will now zero-fill files when extending.

`writable()`

Return `True` if the stream supports writing. If `False`, `write()` and `truncate()` will raise `IOError`.

`writelines(lines, /)`

Write a list of lines to the stream. Line separators are not added, so it is usual for each of the lines provided to have a line separator at the end.

`__del__()`

Prepare for object destruction. `IOBase` provides a default implementation of this method that calls the instance's `close()` method.

`class io.RawIOBase`

Base class for raw binary streams. It inherits `IOBase`.

Raw binary streams typically provide low-level access to an underlying OS device or API, and do not try to encapsulate it in high-level primitives (this functionality is done at a higher-level in buffered binary streams and text streams, described later in this page).

`RawIOBase` provides these methods in addition to those from `IOBase`:

`read(size = -1, /)`

Read up to *size* bytes from the object and return them. As a convenience, if *size* is unspecified or -1, all bytes

until EOF are returned. Otherwise, only one system call is ever made. Fewer than *size* bytes may be returned if the operating system call returns fewer than *size* bytes.

If 0 bytes are returned, and *size* was not 0, this indicates end of file. If the object is in non-blocking mode and no bytes are available, `None` is returned.

The default implementation defers to `readall()` and `readinto()`.

### `readall()`

Read and return all the bytes from the stream until EOF, using multiple calls to the stream if necessary.

### `readinto(b, /)`

Read bytes into a pre-allocated, writable [bytes-like object](#) *b*, and return the number of bytes read. For example, *b* might be a [bytearray](#). If the object is in non-blocking mode and no bytes are available, `None` is returned.

### `write(b, /)`

Write the given [bytes-like object](#), *b*, to the underlying raw stream, and return the number of bytes written. This can be less than the length of *b* in bytes, depending on specifics of the underlying raw stream, and especially if it is in non-blocking mode. `None` is returned if the raw stream is set not to block and no single byte could be readily written to it. The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

### `class io.BufferedIOBase`

Base class for binary streams that support some kind of buffering. It inherits [IOBase](#).

The main difference with `RawIOBase` is that methods `read()`, `readinto()` and `write()` will try (respectively) to read as much input as requested or to consume all given output, at the expense of making perhaps more than one system call.

In addition, those methods can raise `BlockingIOError` if the underlying raw stream is in non-blocking mode and cannot take or give enough data; unlike their `RawIOBase` counterparts, they will never return `None`.

Besides, the `read()` method does not have a default implementation that defers to `readinto()`.

A typical `BufferedIOBase` implementation should not inherit from a `RawIOBase` implementation, but wrap one, like `BufferedWriter` and `BufferedReader` do.

`BufferedIOBase` provides or overrides these data attributes and methods in addition to those from `IOBase`:

`raw`

The underlying raw stream (a `RawIOBase` instance) that `BufferedIOBase` deals with. This is not part of the `BufferedIOBase` API and may not exist on some implementations.

`detach()`

Separate the underlying raw stream from the buffer and return it.

After the raw stream has been detached, the buffer is in an unusable state.

Some buffers, like `BytesIO`, do not have the concept of a single raw stream to return from this method. They raise `UnsupportedOperation`.

*New in version 3.1.*

`read(size = - 1, /)`

Read and return up to *size* bytes. If the argument is omitted, `None`, or negative, data is read and returned until EOF is reached. An empty `bytes` object is returned if the stream is already at EOF.

If the argument is positive, and the underlying raw stream is not interactive, multiple raw reads may be issued to satisfy the byte count (unless EOF is reached first). But for interactive raw streams, at most one raw read will be issued, and a short result does not imply that EOF is imminent.

A `BlockingIOError` is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

`read1(size = - 1, /)`

Read and return up to *size* bytes, with at most one call to the underlying raw stream's `read()` (or `readinto()`) method. This can be useful if you are implementing your own buffering on top of a `BufferedIOBase` object.

If *size* is `-1` (the default), an arbitrary number of bytes are returned (more than zero unless EOF is reached).

`readinto(b, /)`

Read bytes into a pre-allocated, writable `bytes-like` object *b* and return the number of bytes read. For example, *b* might be a `bytearray`.

Like `read()`, multiple reads may be issued to the underlying raw stream, unless the latter is interactive.

A `BlockingIOError` is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

`readinto1(b, /)`

Read bytes into a pre-allocated, writable **bytes-like object** *b*, using at most one call to the underlying raw stream's `read()` (or `readinto()`) method. Return the number of bytes read.

A **BlockingIOError** is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

*New in version 3.5.*

`write(b, /)`

Write the given **bytes-like object**, *b*, and return the number of bytes written (always equal to the length of *b* in bytes, since if the write fails an **OSError** will be raised). Depending on the actual implementation, these bytes may be readily written to the underlying stream, or held in a buffer for performance and latency reasons.

When in non-blocking mode, a **BlockingIOError** is raised if the data needed to be written to the raw stream but it couldn't accept all the data without blocking.

The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

## Raw File I/O

`class io.FileIO(name, mode='r', closefd=True, opener=None)`

A raw binary stream representing an OS-level file containing bytes data. It inherits **RawIOBase**.

The *name* can be one of two things:

- a character string or **bytes** object representing the path to the file which will be opened. In this case

`closefd` must be `True` (the default) otherwise an error will be raised.

- an integer representing the number of an existing OS-level file descriptor to which the resulting `FileIO` object will give access. When the `FileIO` object is closed this `fd` will be closed as well, unless `closefd` is set to `False`.

The *mode* can be `'r'`, `'w'`, `'x'` or `'a'` for reading (default), writing, exclusive creation or appending. The file will be created if it doesn't exist when opened for writing or appending; it will be truncated when opened for writing. `FileExistsError` will be raised if it already exists when opened for creating. Opening a file for creating implies writing, so this mode behaves in a similar way to `'w'`. Add a `'+'` to the mode to allow simultaneous reading and writing.

The `read()` (when called with a positive argument), `readinto()` and `write()` methods on this class will only make one system call.

A custom opener can be used by passing a callable as *opener*. The underlying file descriptor for the file object is then obtained by calling *opener* with (*name*, *flags*). *opener* must return an open file descriptor (passing `os.open` as *opener* results in functionality similar to passing `None`).

The newly created file is `non-inheritable`.

See the `open()` built-in function for examples on using the *opener* parameter.

*Changed in version 3.3:* The *opener* parameter was added. The `'x'` mode was added.

*Changed in version 3.4:* The file is now non-inheritable.

`FileIO` provides these data attributes in addition to those from `RawIOBase` and `IOBase`:

`mode`

The mode as given in the constructor.

name

The file name. This is the file descriptor of the file when no name is given in the constructor.

## Buffered Streams

Buffered I/O streams provide a higher-level interface to an I/O device than raw I/O does.

*class* io.BytesIO(*initial\_bytes=b''*)

A binary stream using an in-memory bytes buffer. It inherits **BufferedIOBase**. The buffer is discarded when the **close()** method is called.

The optional argument *initial\_bytes* is a **bytes-like object** that contains initial data.

**BytesIO** provides or overrides these methods in addition to those from **BufferedIOBase** and **IOBase**:

getbuffer()

Return a readable and writable view over the contents of the buffer without copying them. Also, mutating the view will transparently update the contents of the buffer:

```
>>> b = io.BytesIO(b"abcdef")
>>> view = b.getbuffer()
>>> view[2:4] = b"56"
>>> b.getvalue()
b'ab56ef'
```

### Note

As long as the view exists, the **BytesIO** object cannot be resized or closed.

*New in version 3.2.*

`getvalue()`

Return **bytes** containing the entire contents of the buffer.

`read1(size = - 1, /)`

In **BytesIO**, this is the same as `read()`.

*Changed in version 3.7:* The *size* argument is now optional.

`readinto1(b, /)`

In **BytesIO**, this is the same as `readinto()`.

*New in version 3.5.*

`class io.BufferedReader(raw, buffer_size = DEFAULT_BUFFER_SIZE)`

A buffered binary stream providing higher-level access to a readable, non seekable **RawIOBase** raw binary stream. It inherits **BufferedIOBase**.

When reading data from this object, a larger amount of data may be requested from the underlying raw stream, and kept in an internal buffer. The buffered data can then be returned directly on subsequent reads.

The constructor creates a **BufferedReader** for the given readable *raw* stream and *buffer\_size*. If *buffer\_size* is omitted, **DEFAULT\_BUFFER\_SIZE** is used.

**BufferedReader** provides or overrides these methods in addition to those from **BufferedIOBase** and **IOBase**:

`peek(size = 0, /)`

Return bytes from the stream without advancing the position. At most one single read on the raw stream is done to satisfy the call. The number of bytes returned

may be less or more than requested.

`read(size = - 1, /)`

Read and return *size* bytes, or if *size* is not given or negative, until EOF or if the read call would block in non-blocking mode.

`read1(size = - 1, /)`

Read and return up to *size* bytes with only one call on the raw stream. If at least one byte is buffered, only buffered bytes are returned. Otherwise, one raw stream read call is made.

*Changed in version 3.7:* The *size* argument is now optional.

`class io.BufferedWriter(raw, buffer_size = DEFAULT_BUFFER_SIZE)`

A buffered binary stream providing higher-level access to a writeable, non seekable `RawIOBase` raw binary stream. It inherits `BufferedIOBase`.

When writing to this object, data is normally placed into an internal buffer. The buffer will be written out to the underlying `RawIOBase` object under various conditions, including:

- when the buffer gets too small for all pending data;
- when `flush()` is called;
- when a `seek()` is requested (for `BufferedRandom` objects);
- when the `BufferedWriter` object is closed or destroyed.

The constructor creates a `BufferedWriter` for the given writeable *raw* stream. If the *buffer\_size* is not given, it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedWriter` provides or overrides these methods in addition to those from `BufferedIOBase` and `IOBase`:

`flush()`

Force bytes held in the buffer into the raw stream. A `BlockingIOError` should be raised if the raw stream blocks.

`write(b, /)`

Write the `bytes-like object`, `b`, and return the number of bytes written. When in non-blocking mode, a `BlockingIOError` is raised if the buffer needs to be written out but the raw stream blocks.

`class io.BufferedRandom(raw, buffer_size=DEFAULT_BUFFER_SIZE)`

A buffered binary stream providing higher-level access to a seekable `RawIOBase` raw binary stream. It inherits `BufferedReader` and `BufferedWriter`.

The constructor creates a reader and writer for a seekable raw stream, given in the first argument. If the `buffer_size` is omitted it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedRandom` is capable of anything `BufferedReader` or `BufferedWriter` can do. In addition, `seek()` and `tell()` are guaranteed to be implemented.

`class io.BufferedRWPair(reader, writer,  
buffer_size=DEFAULT_BUFFER_SIZE, /)`

A buffered binary stream providing higher-level access to two non seekable `RawIOBase` raw binary streams—one readable, the other writeable. It inherits `BufferedIOBase`.

`reader` and `writer` are `RawIOBase` objects that are readable and writeable respectively. If the `buffer_size` is omitted it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedRWPair` implements all of `BufferedIOBase`'s methods except for `detach()`, which raises `UnsupportedOperation`.

## Warning

`BufferedReader` does not attempt to synchronize accesses to its underlying raw streams. You should not pass it the same object as reader and writer; use `BufferedReader` instead.

## Text I/O

*class* `io.TextIOBase`

Base class for text streams. This class provides a character and line based interface to stream I/O. It inherits `IOBase`.

`TextIOBase` provides or overrides these data attributes and methods in addition to those from `IOBase`:

`encoding`

The name of the encoding used to decode the stream's bytes into strings, and to encode strings into bytes.

`errors`

The error setting of the decoder or encoder.

`newlines`

A string, a tuple of strings, or `None`, indicating the newlines translated so far. Depending on the implementation and the initial constructor flags, this may not be available.

`buffer`

The underlying binary buffer (a `BufferedIOBase` instance) that `TextIOBase` deals with. This is not part of the `TextIOBase` API and may not exist in some implementations.

`detach()`

Separate the underlying binary buffer from the

**TextIOBase** and return it.

After the underlying buffer has been detached, the **TextIOBase** is in an unusable state.

Some **TextIOBase** implementations, like **StringIO**, may not have the concept of an underlying buffer and calling this method will raise **UnsupportedOperation**.

*New in version 3.1.*

`read(size = - 1, /)`

Read and return at most *size* characters from the stream as a single `str`. If *size* is negative or `None`, reads until EOF.

`readline(size = - 1, /)`

Read until newline or EOF and return a single `str`. If the stream is already at EOF, an empty string is returned.

If *size* is specified, at most *size* characters will be read.

`seek(offset, whence = SEEK_SET, /)`

Change the stream position to the given *offset*. Behaviour depends on the *whence* parameter. The default value for *whence* is **SEEK\_SET**.

- **SEEK\_SET** or 0: seek from the start of the stream (the default); *offset* must either be a number returned by **TextIOBase.tell()**, or zero. Any other *offset* value produces undefined behaviour.
- **SEEK\_CUR** or 1: “seek” to the current position; *offset* must be zero, which is a no-operation (all other values are unsupported).
- **SEEK\_END** or 2: seek to the end of the stream; *offset* must be zero (all other values are

unsupported).

Return the new absolute position as an opaque number.

*New in version 3.1:* The `SEEK_*` constants.

`tell()`

Return the current stream position as an opaque number. The number does not usually represent a number of bytes in the underlying binary storage.

`write(s, /)`

Write the string *s* to the stream and return the number of characters written.

`class io.TextIOWrapper(buffer, encoding=None, errors=None, newline=None, line_buffering=False, write_through=False)`

A buffered text stream providing higher-level access to a [BufferedIOBase](#) buffered binary stream. It inherits [TextIOBase](#).

*encoding* gives the name of the encoding that the stream will be decoded or encoded with. It defaults to [locale.getencoding\(\)](#). `encoding="locale"` can be used to specify the current locale's encoding explicitly. See [Text Encoding](#) for more information.

*errors* is an optional string that specifies how encoding and decoding errors are to be handled. Pass `'strict'` to raise a [ValueError](#) exception if there is an encoding error (the default of `None` has the same effect), or pass `'ignore'` to ignore errors. (Note that ignoring encoding errors can lead to data loss.) `'replace'` causes a replacement marker (such as `'?'`) to be inserted where there is malformed data. `'backslashreplace'` causes malformed data to be replaced by a backslashed escape sequence. When writing, `'xmlcharrefreplace'` (replace with the appropriate XML character reference) or `'namereplace'` (replace with `\N{...}` escape sequences) can be used. Any other error

handling name that has been registered with `codecs.register_error()` is also valid.

*newline* controls how line endings are handled. It can be `None`, `' '`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows:

- When reading input from the stream, if *newline* is `None`, `universal newlines` mode is enabled. Lines in the input can end in `'\n'`, `'\r'`, or `'\r\n'`, and these are translated into `'\n'` before being returned to the caller. If *newline* is `' '`, universal newlines mode is enabled, but line endings are returned to the caller untranslated. If *newline* has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- When writing output to the stream, if *newline* is `None`, any `'\n'` characters written are translated to the system default line separator, `os.linesep`. If *newline* is `' '` or `'\n'`, no translation takes place. If *newline* is any of the other legal values, any `'\n'` characters written are translated to the given string.

If *line\_buffering* is `True`, `flush()` is implied when a call to write contains a newline character or a carriage return.

If *write\_through* is `True`, calls to `write()` are guaranteed not to be buffered: any data written on the `TextIOWrapper` object is immediately handled to its underlying binary *buffer*.

*Changed in version 3.3:* The *write\_through* argument has been added.

*Changed in version 3.3:* The default *encoding* is now `locale.getpreferredencoding(False)` instead of `locale.getpreferredencoding()`. Don't change temporary the locale encoding using `locale.setlocale()`, use the current locale encoding instead of the user preferred encoding.

*Changed in version 3.10:* The *encoding* argument now supports

the "locale" dummy encoding name.

**TextIOWrapper** provides these data attributes and methods in addition to those from **TextIOBase** and **IOBase**:

**line\_buffering**

Whether line buffering is enabled.

**write\_through**

Whether writes are passed immediately to the underlying binary buffer.

*New in version 3.7.*

**reconfigure**(\*, *encoding=None, errors=None, newline=None, line\_buffering=None, write\_through=None*)

Reconfigure this text stream using new settings for *encoding, errors, newline, line\_buffering* and *write\_through*.

Parameters not specified keep current settings, except *errors='strict'* is used when *encoding* is specified but *errors* is not specified.

It is not possible to change the encoding or newline if some data has already been read from the stream. On the other hand, changing encoding after write is possible.

This method does an implicit stream flush before setting the new parameters.

*New in version 3.7.*

*Changed in version 3.11:* The method supports *encoding="locale"* option.

**class** io.StringIO(*initial\_value=""*, *newline='\n'*)

A text stream using an in-memory text buffer. It inherits **TextIOBase**.

The text buffer is discarded when the `close()` method is called.

The initial value of the buffer can be set by providing *initial\_value*. If newline translation is enabled, newlines will be encoded as if by `write()`. The stream is positioned at the start of the buffer which emulates opening an existing file in a `w+` mode, making it ready for an immediate write from the beginning or for a write that would overwrite the initial value. To emulate opening a file in an `a+` mode ready for appending, use `f.seek(0, io.SEEK_END)` to reposition the stream at the end of the buffer.

The *newline* argument works like that of `TextIOWrapper`, except that when writing output to the stream, if *newline* is `None`, newlines are written as `\n` on all platforms.

`StringIO` provides this method in addition to those from `TextIOBase` and `IOBase`:

`getvalue()`

Return a `str` containing the entire contents of the buffer. Newlines are decoded as if by `read()`, although the stream position is not changed.

Example usage:

```
import io

output = io.StringIO()
output.write('First line.\n')
print('Second line.', file=output)

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

`class io.IncrementalNewlineDecoder`

A helper codec that decodes newlines for [universal newlines](#) mode. It inherits [codecs.IncrementalDecoder](#).

## Performance

This section discusses the performance of the provided concrete I/O implementations.

### Binary I/O

By reading and writing only large chunks of data even when the user asks for a single byte, buffered I/O hides any inefficiency in calling and executing the operating system's unbuffered I/O routines. The gain depends on the OS and the kind of I/O which is performed. For example, on some modern OSes such as Linux, unbuffered disk I/O can be as fast as buffered I/O. The bottom line, however, is that buffered I/O offers predictable performance regardless of the platform and the backing device. Therefore, it is almost always preferable to use buffered I/O rather than unbuffered I/O for binary data.

### Text I/O

Text I/O over a binary storage (such as a file) is significantly slower than binary I/O over the same storage, because it requires conversions between unicode and binary data using a character codec. This can become noticeable handling huge amounts of text data like large log files. Also, **`TextIOWrapper.tell()`** and **`TextIOWrapper.seek()`** are both quite slow due to the reconstruction algorithm used.

[StringIO](#), however, is a native in-memory unicode container and will exhibit similar speed to [BytesIO](#).

### Multi-threading

[FileIO](#) objects are thread-safe to the extent that the operating system calls (such as `read(2)` under Unix) they wrap are thread-

safe too.

Binary buffered objects (instances of `BufferedReader`, `BufferedWriter`, `BufferedRandom` and `BufferedRWPair`) protect their internal structures using a lock; it is therefore safe to call them from multiple threads at once.

`TextIOWrapper` objects are not thread-safe.

## Reentrancy

Binary buffered objects (instances of `BufferedReader`, `BufferedWriter`, `BufferedRandom` and `BufferedRWPair`) are not reentrant. While reentrant calls will not happen in normal situations, they can arise from doing I/O in a `signal` handler. If a thread tries to re-enter a buffered object which it is already accessing, a `RuntimeError` is raised. Note this doesn't prohibit a different thread from entering the buffered object.

The above implicitly extends to text files, since the `open()` function will wrap a buffered object inside a `TextIOWrapper`. This includes standard streams and therefore affects the built-in `print()` function as well.

# time — Time access and conversions

---

This module provides various time-related functions. For related functionality, see also the `datetime` and `calendar` modules.

Although this module is always available, not all functions are available on all platforms. Most of the functions defined in this module call platform C library functions with the same name. It may sometimes be helpful to consult the platform documentation, because the semantics of these functions varies among platforms.

An explanation of some terminology and conventions is in order.

- The *epoch* is the point where the time starts, the return value of `time.gmtime(0)`. It is January 1, 1970, 00:00:00 (UTC) on all platforms.
- The term *seconds since the epoch* refers to the total number of elapsed seconds since the epoch, typically excluding [leap seconds](https://en.wikipedia.org/wiki/Leap_second) [https://en.wikipedia.org/wiki/Leap\_second]. Leap seconds are excluded from this total on all POSIX-compliant platforms.
- The functions in this module may not handle dates and times before the [epoch](#) or far in the future. The cut-off point in the future is determined by the C library; for 32-bit systems, it is typically in 2038.
- Function `strptime()` can parse 2-digit years when given `%y` format code. When 2-digit years are parsed, they are converted according to the POSIX and ISO C standards: values 69–99 are mapped to 1969–1999, and values 0–68 are mapped to 2000–2068.

- UTC is Coordinated Universal Time (formerly known as Greenwich Mean Time, or GMT). The acronym UTC is not a mistake but a compromise between English and French.
- DST is Daylight Saving Time, an adjustment of the timezone by (usually) one hour during part of the year. DST rules are magic (determined by local law) and can change from year to year. The C library has a table containing the local rules (often it is read from a system file for flexibility) and is the only source of True Wisdom in this respect.
- The precision of the various real-time functions may be less than suggested by the units in which their value or argument is expressed. E.g. on most Unix systems, the clock “ticks” only 50 or 100 times a second.
- On the other hand, the precision of `time()` and `sleep()` is better than their Unix equivalents: times are expressed as floating point numbers, `time()` returns the most accurate time available (using Unix `gettimeofday()` where available), and `sleep()` will accept a time with a nonzero fraction (Unix `select()` is used to implement this, where available).
- The time value as returned by `gmtime()`, `localtime()`, and `strptime()`, and accepted by `asctime()`, `mktime()` and `strftime()`, is a sequence of 9 integers. The return values of `gmtime()`, `localtime()`, and `strptime()` also offer attribute names for individual fields.

See `struct_time` for a description of these objects.

*Changed in version 3.3:* The `struct_time` type was extended to provide the `tm_gmtoff` and `tm_zone` attributes when platform supports corresponding `struct tm` members.

*Changed in version 3.6:* The `struct_time` attributes `tm_gmtoff` and `tm_zone` are now available on all platforms.

- Use the following functions to convert between time

representations:

**Item**

---

`seconds` since the epoch

---

`seconds` since the local time

---

`seconds` since the epoch

---

`seconds` since the local time

---

## Functions

`time.asctime([t])`

Convert a tuple or `struct_time` representing a time as returned by `gmtime()` or `localtime()` to a string of the following form: 'Sun Jun 20 23:21:05 1993'. The day field is two characters long and is space padded if the day is a single digit, e.g.: 'Wed Jun 9 04:26:40 1993'.

If *t* is not provided, the current time as returned by `localtime()` is used. Locale information is not used by `asctime()`.

### Note

Unlike the C function of the same name, `asctime()` does not add a trailing newline.

`time.thread_getcpuclockid(thread_id)`

Return the *clk\_id* of the thread-specific CPU-time clock for the specified *thread\_id*.

Use `threading.get_ident()` or the *ident* attribute of `threading.Thread` objects to get a suitable value for *thread\_id*.

### Warning

Passing an invalid or expired *thread\_id* may result in undefined behavior, such as segmentation fault.

**Availability:** Unix

See the man page for [\*pthread\\_getcpuclockid\(3\)\*](#) for further information.

*New in version 3.7.*

`time.clock_getres(clk_id)`

Return the resolution (precision) of the specified clock *clk\_id*. Refer to [Clock ID Constants](#) for a list of accepted values for *clk\_id*.

**Availability:** Unix.

*New in version 3.3.*

`time.clock_gettime(clk_id) → float`

Return the time of the specified clock *clk\_id*. Refer to [Clock ID Constants](#) for a list of accepted values for *clk\_id*.

Use `clock_gettime_ns()` to avoid the precision loss caused by the `float` type.

**Availability:** Unix.

*New in version 3.3.*

`time.clock_gettime_ns(clk_id) → int`

Similar to `clock_gettime()` but return time as nanoseconds.

**Availability:** Unix.

*New in version 3.7.*

`time.clock_settime(clk_id, time: float)`

Set the time of the specified clock *clk\_id*. Currently, `CLOCK_REALTIME` is the only accepted value for *clk\_id*.

Use `clock_gettime_ns()` to avoid the precision loss caused by the `float` type.

*Availability:* Unix.

*New in version 3.3.*

`time.clock_gettime_ns(clk_id, time: int)`

Similar to `clock_gettime()` but set time with nanoseconds.

*Availability:* Unix.

*New in version 3.7.*

`time.ctime([secs])`

Convert a time expressed in seconds since the `epoch` to a string of a form: 'Sun Jun 20 23:21:05 1993' representing local time. The day field is two characters long and is space padded if the day is a single digit, e.g.: 'Wed Jun 9 04:26:40 1993'.

If `secs` is not provided or `None`, the current time as returned by `time()` is used. `ctime(secs)` is equivalent to `asctime(localtime(secs))`. Locale information is not used by `ctime()`.

`time.get_clock_info(name)`

Get information on the specified clock as a namespace object. Supported clock names and the corresponding functions to read their value are:

- 'monotonic': `time.monotonic()`
- 'perf\_counter': `time.perf_counter()`
- 'process\_time': `time.process_time()`
- 'thread\_time': `time.thread_time()`
- 'time': `time.time()`

The result has the following attributes:

- *adjustable*: `True` if the clock can be changed automatically (e.g. by a NTP daemon) or manually by the system administrator, `False` otherwise
- *implementation*: The name of the underlying C function used to get the clock value. Refer to [Clock ID Constants](#) for possible values.
- *monotonic*: `True` if the clock cannot go backward, `False` otherwise
- *resolution*: The resolution of the clock in seconds (`float`)

*New in version 3.3.*

`time.gmtime([secs])`

Convert a time expressed in seconds since the [epoch](#) to a [struct\\_time](#) in UTC in which the dst flag is always zero. If `secs` is not provided or `None`, the current time as returned by [time\(\)](#) is used. Fractions of a second are ignored. See above for a description of the [struct\\_time](#) object. See [calendar.timegm\(\)](#) for the inverse of this function.

`time.localtime([secs])`

Like [gmtime\(\)](#) but converts to local time. If `secs` is not provided or `None`, the current time as returned by [time\(\)](#) is used. The dst flag is set to `1` when DST applies to the given time.

[localtime\(\)](#) may raise [OverflowError](#), if the timestamp is outside the range of values supported by the platform C [localtime\(\)](#) or [gmtime\(\)](#) functions, and [OSError](#) on [localtime\(\)](#) or [gmtime\(\)](#) failure. It's common for this to be restricted to years between 1970 and 2038.

`time.mktime(t)`

This is the inverse function of [localtime\(\)](#). Its argument is the [struct\\_time](#) or full 9-tuple (since the dst flag is needed; use `-1` as the dst flag if it is unknown) which expresses the time in *local* time, not UTC. It returns a floating

point number, for compatibility with `time()`. If the input value cannot be represented as a valid time, either `OverflowError` or `ValueError` will be raised (which depends on whether the invalid value is caught by Python or the underlying C libraries). The earliest date for which it can generate a time is platform-dependent.

`time.monotonic()` → `float`

Return the value (in fractional seconds) of a monotonic clock, i.e. a clock that cannot go backwards. The clock is not affected by system clock updates. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Use `monotonic_ns()` to avoid the precision loss caused by the `float` type.

*New in version 3.3.*

*Changed in version 3.5:* The function is now always available and always system-wide.

*Changed in version 3.10:* On macOS, the function is now system-wide.

`time.monotonic_ns()` → `int`

Similar to `monotonic()`, but return time as nanoseconds.

*New in version 3.7.*

`time.perf_counter()` → `float`

Return the value (in fractional seconds) of a performance counter, i.e. a clock with the highest available resolution to measure a short duration. It does include time elapsed during sleep and is system-wide. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Use `perf_counter_ns()` to avoid the precision loss caused

by the `float` type.

*New in version 3.3.*

*Changed in version 3.10:* On Windows, the function is now system-wide.

`time.perf_counter_ns()` → `int`

Similar to `perf_counter()`, but return time as nanoseconds.

*New in version 3.7.*

`time.process_time()` → `float`

Return the value (in fractional seconds) of the sum of the system and user CPU time of the current process. It does not include time elapsed during sleep. It is process-wide by definition. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Use `process_time_ns()` to avoid the precision loss caused by the `float` type.

*New in version 3.3.*

`time.process_time_ns()` → `int`

Similar to `process_time()` but return time as nanoseconds.

*New in version 3.7.*

`time.sleep(secs)`

Suspend execution of the calling thread for the given number of seconds. The argument may be a floating point number to indicate a more precise sleep time.

If the sleep is interrupted by a signal and no exception is raised by the signal handler, the sleep is restarted with a

recomputed timeout.

The suspension time may be longer than requested by an arbitrary amount, because of the scheduling of other activity in the system.

On Windows, if `secs` is zero, the thread relinquishes the remainder of its time slice to any other thread that is ready to run. If there are no other threads ready to run, the function returns immediately, and the thread continues execution. On Windows 8.1 and newer the implementation uses a [high-resolution timer](https://docs.microsoft.com/en-us/windows-hardware/drivers/kernel/high-resolution-timers) [https://docs.microsoft.com/en-us/windows-hardware/drivers/kernel/high-resolution-timers] which provides resolution of 100 nanoseconds. If `secs` is zero, `Sleep(0)` is used.

Unix implementation:

- Use `clock_nanosleep()` if available (resolution: 1 nanosecond);
- Or use `nanosleep()` if available (resolution: 1 nanosecond);
- Or use `select()` (resolution: 1 microsecond).

*Changed in version 3.11:* On Unix, the `clock_nanosleep()` and `nanosleep()` functions are now used if available. On Windows, a waitable timer is now used.

*Changed in version 3.5:* The function now sleeps at least `secs` even if the sleep is interrupted by a signal, except if the signal handler raises an exception (see [PEP 475](https://peps.python.org/pep-0475/) [https://peps.python.org/pep-0475/] for the rationale).

`time.strftime(format[, t])`

Convert a tuple or `struct_time` representing a time as returned by `gmtime()` or `localtime()` to a string as specified by the `format` argument. If `t` is not provided, the current time as returned by `localtime()` is used. `format` must be a string. `ValueError` is raised if any field in `t` is outside of the allowed range.

0 is a legal argument for any position in the time tuple; if it is

normally illegal the value is forced to a correct one.

The following directives can be embedded in the *format* string. They are shown without the optional field width and precision specification, and are replaced by the indicated characters in the `strftime()` result:

### **~~Metas~~ing**

---

~~L~~ocale's abbreviated weekday name.

---

~~L~~ocale's full weekday name.

---

~~L~~ocale's abbreviated month name.

---

~~L~~ocale's full month name.

---

~~L~~ocale's appropriate date and time representation.

---

~~D~~ay of the month as a decimal number [01,31].

---

~~H~~our (24-hour clock) as a decimal number [00,23].

---

~~H~~our (12-hour clock) as a decimal number [01,12].

---

~~D~~ay of the year as a decimal number [001,366].

---

~~M~~onth as a decimal number [01,12].

---

~~M~~inute as a decimal number [00,59].

---

~~P~~ocale's equivalent of either AM or PM.

---

~~S~~econd as a decimal number [00,61].

---

~~W~~eek number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.

---

~~W~~eekday as a decimal number [0(Sunday),6].

---

~~W~~eek number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.

---

~~L~~ocale's appropriate date representation.

---

~~L~~ocale's appropriate time representation.

---

~~Y~~ear without century as a decimal number [00,99].

---

~~Y~~ear with century as a decimal number.

---

~~T~~ime zone offset indicating a positive or negative time difference from UTC/GMT of the form +HHMM or -HHMM, where H represents decimal hour digits and M represents decimal minute digits [-23:59, +23:59]. [1](#)

---

~~T~~ime zone name (no characters if no time zone exists).

---

Deprecated. [1](#)

---

~~A~~literal '%' character.

---

Notes:

1. When used with the `strptime()` function, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.
2. The range really is 0 to 61; value 60 is valid in timestamps representing [leap seconds](https://en.wikipedia.org/wiki/Leap_second) [https://en.wikipedia.org/wiki/Leap\_second] and value 61 is supported for historical reasons.
3. When used with the `strptime()` function, `%U` and `%W` are only used in calculations when the day of the week and the year are specified.

Here is an example, a format for dates compatible with that specified in the [RFC 2822](https://datatracker.ietf.org/doc/html/rfc2822.html) [https://datatracker.ietf.org/doc/html/rfc2822.html] Internet email standard. 1

```
>>> from time import gmtime, strftime
>>> strftime("%a, %d %b %Y %H:%M:%S +0000", gmtime(
'Thu, 28 Jun 2001 14:17:15 +0000'
```

Additional directives may be supported on certain platforms, but only the ones listed here have a meaning standardized by ANSI C. To see the full set of format codes supported on your platform, consult the [strftime\(3\)](#) documentation.

On some platforms, an optional field width and precision specification can immediately follow the initial `'%'` of a directive in the following order; this is also not portable. The field width is normally 2 except for `%j` where it is 3.

`time.strptime(string[, format])`

Parse a string representing a time according to a format. The return value is a `struct_time` as returned by `gmtime()` or `localtime()`.

The *format* parameter uses the same directives as those used by `strftime()`; it defaults to `"%a %b %d %H:%M:%S %Y"` which matches the formatting returned by `ctime()`. If *string* cannot be parsed according to *format*, or if it has excess data after parsing, `ValueError` is raised. The default values used to fill in any missing data when more accurate values

cannot be inferred are (1900, 1, 1, 0, 0, 0, 0, 1, -1). Both *string* and *format* must be strings.

For example:

```
>>> import time
>>> time.strptime("30 Nov 00", "%d %b %y")
time.struct_time(tm_year=2000, tm_mon=11, tm_mday=30,
                  tm_sec=0, tm_wday=3, tm_yday=335,
```

Support for the `%Z` directive is based on the values contained in `tzname` and whether `daylight` is true. Because of this, it is platform-specific except for recognizing UTC and GMT which are always known (and are considered to be non-daylight savings timezones).

Only the directives specified in the documentation are supported. Because `strptime()` is implemented per platform it can sometimes offer more directives than those listed. But `strptime()` is independent of any platform and thus does not necessarily support all directives available that are not documented as supported.

*class* `time.struct_time`

The type of the time value sequence returned by `gmtime()`, `localtime()`, and `strptime()`. It is an object with a `named tuple` interface: values can be accessed by index and by attribute name. The following values are present:

| Attribute |
|-----------|
|-----------|

|                      |                   |
|----------------------|-------------------|
| <code>tm_year</code> | For example, 1993 |
|----------------------|-------------------|

|                     |        |
|---------------------|--------|
| <code>tm_mon</code> | 1, 12] |
|---------------------|--------|

|                      |        |
|----------------------|--------|
| <code>tm_mday</code> | 1, 31] |
|----------------------|--------|

|                      |        |
|----------------------|--------|
| <code>tm_hour</code> | 0, 23] |
|----------------------|--------|

|                     |        |
|---------------------|--------|
| <code>tm_min</code> | 0, 59] |
|---------------------|--------|

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| <code>tm_sec</code> | 0, 61]; see (2) in <code>strptime()</code> description |
|---------------------|--------------------------------------------------------|

|                      |                    |
|----------------------|--------------------|
| <code>tm_wday</code> | 0, 6], Monday is 0 |
|----------------------|--------------------|

|                      |         |
|----------------------|---------|
| <code>tm_yday</code> | 0, 366] |
|----------------------|---------|

|                       |           |
|-----------------------|-----------|
| <code>tm_isdst</code> | see below |
|-----------------------|-----------|

|                      |                               |
|----------------------|-------------------------------|
| <code>tm_zone</code> | Abbreviation of timezone name |
|----------------------|-------------------------------|

## Offset of UTC in seconds

---

Note that unlike the C structure, the month value is a range of [1, 12], not [0, 11].

In calls to `mktime()`, `tm_isdst` may be set to 1 when daylight savings time is in effect, and 0 when it is not. A value of -1 indicates that this is not known, and will usually result in the correct state being filled in.

When a tuple with an incorrect length is passed to a function expecting a `struct_time`, or having elements of the wrong type, a `TypeError` is raised.

`time.time()` → `float`

Return the time in seconds since the `epoch` as a floating point number. The handling of `leap seconds` [[https://en.wikipedia.org/wiki/Leap\\_second](https://en.wikipedia.org/wiki/Leap_second)] is platform dependent. On Windows and most Unix systems, the leap seconds are not counted towards the time in seconds since the `epoch`. This is commonly referred to as `Unix time` [[https://en.wikipedia.org/wiki/Unix\\_time](https://en.wikipedia.org/wiki/Unix_time)].

Note that even though the time is always returned as a floating point number, not all systems provide time with a better precision than 1 second. While this function normally returns non-decreasing values, it can return a lower value than a previous call if the system clock has been set back between the two calls.

The number returned by `time()` may be converted into a more common time format (i.e. year, month, day, hour, etc...) in UTC by passing it to `gmtime()` function or in local time by passing it to the `localtime()` function. In both cases a `struct_time` object is returned, from which the components of the calendar date may be accessed as attributes.

Use `time_ns()` to avoid the precision loss caused by the `float` type.

`time.time_ns()` → `int`

Similar to `time()` but returns time as an integer number of nanoseconds since the `epoch`.

*New in version 3.7.*

`time.thread_time()` → `float`

Return the value (in fractional seconds) of the sum of the system and user CPU time of the current thread. It does not include time elapsed during sleep. It is thread-specific by definition. The reference point of the returned value is undefined, so that only the difference between the results of two calls in the same thread is valid.

Use `thread_time_ns()` to avoid the precision loss caused by the `float` type.

**Availability:** Linux, Unix, Windows.

Unix systems supporting `CLOCK_THREAD_CPUTIME_ID`.

*New in version 3.7.*

`time.thread_time_ns()` → `int`

Similar to `thread_time()` but return time as nanoseconds.

*New in version 3.7.*

`time.tzset()`

Reset the time conversion rules used by the library routines. The environment variable `TZ` specifies how this is done. It will also set the variables `tzname` (from the `TZ` environment variable), `timezone` (non-DST seconds West of UTC), `altzone` (DST seconds west of UTC) and `daylight` (to 0 if this timezone does not have any daylight saving time rules, or to nonzero if there is a time, past, present or future when daylight saving time applies).

**Availability:** Unix.

## Note

Although in many cases, changing the **TZ** environment variable may affect the output of functions like `localtime()` without calling `tzset()`, this behavior should not be relied on.

The **TZ** environment variable should contain no whitespace.

The standard format of the **TZ** environment variable is (whitespace added for clarity):

```
std offset [dst [offset [,start[/time], end[/time]]]
```

Where the components are:

`std` and `dst`

Three or more alphanumerics giving the timezone abbreviations. These will be propagated into `time.tzname`

`offset`

The offset has the form:  $\pm hh[:mm[:ss]]$ . This indicates the value added the local time to arrive at UTC. If preceded by a '-', the timezone is east of the Prime Meridian; otherwise, it is west. If no offset follows `dst`, summer time is assumed to be one hour ahead of standard time.

`start[/time], end[/time]`

Indicates when to change to and back from DST. The format of the start and end dates are one of the following:

$J_n$

The Julian day  $n$  ( $1 \leq n \leq 365$ ). Leap days are not counted, so in all years February 28 is day 59 and March 1 is day 60.

$n$

The zero-based Julian day ( $0 \leq n \leq 365$ ). Leap days are counted, and it is possible to refer to February 29.

$Mm.n.d$

The  $d$ 'th day ( $0 \leq d \leq 6$ ) of week  $n$  of month  $m$  of the year ( $1 \leq n \leq 5$ ,  $1 \leq m \leq 12$ , where week 5 means “the last  $d$  day in month  $m$ ” which may occur in either the fourth or the fifth week). Week 1 is the first week in which the  $d$ 'th day occurs. Day zero is a Sunday.

`time` has the same format as `offset` except that no leading sign ('-' or '+') is allowed. The default, if `time` is not given, is 02:00:00.

```
>>> os.environ['TZ'] = 'EST+05EDT,M4.1.0,M10.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'02:07:36 05/08/03 EDT'
>>> os.environ['TZ'] = 'AEST-10AEDT-11,M10.5.0,M3.5
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'16:08:12 05/08/03 AEST'
```

On many Unix systems (including \*BSD, Linux, Solaris, and Darwin), it is more convenient to use the system's zoneinfo ([tzfile\(5\)](#)) database to specify the timezone rules. To do this, set the **TZ** environment variable to the path of the required timezone datafile, relative to the root of the systems 'zoneinfo' timezone database, usually located at `/usr/share/zoneinfo`. For example, 'US/Eastern', 'Australia/Melbourne', 'Egypt' or 'Europe/Amsterdam'.

```
>>> os.environ['TZ'] = 'US/Eastern'
>>> time.tzset()
>>> time.tzname
('EST', 'EDT')
```

```
>>> os.environ['TZ'] = 'Egypt'
>>> time.tzset()
>>> time.tzname
('EET', 'EEST')
```

## Clock ID Constants

These constants are used as parameters for `clock_getres()` and `clock_gettime()`.

`time.CLOCK_BOOTTIME`

Identical to `CLOCK_MONOTONIC`, except it also includes any time that the system is suspended.

This allows applications to get a suspend-aware monotonic clock without having to deal with the complications of `CLOCK_REALTIME`, which may have discontinuities if the time is changed using `settimeofday()` or similar.

**Availability:** Linux  $\geq$  2.6.39.

*New in version 3.7.*

`time.CLOCK_HIGHRES`

The Solaris OS has a `CLOCK_HIGHRES` timer that attempts to use an optimal hardware source, and may give close to nanosecond resolution. `CLOCK_HIGHRES` is the nonadjustable, high-resolution clock.

**Availability:** Solaris.

*New in version 3.3.*

`time.CLOCK_MONOTONIC`

Clock that cannot be set and represents monotonic time since some unspecified starting point.

**Availability:** Unix.

*New in version 3.3.*

time.CLOCK\_MONOTONIC\_RAW

Similar to [CLOCK\\_MONOTONIC](#), but provides access to a raw hardware-based time that is not subject to NTP adjustments.

[Availability](#): Linux  $\geq$  2.6.28, macOS  $\geq$  10.12.

*New in version 3.3.*

time.CLOCK\_PROCESS\_CPUTIME\_ID

High-resolution per-process timer from the CPU.

[Availability](#): Unix.

*New in version 3.3.*

time.CLOCK\_PROF

High-resolution per-process timer from the CPU.

[Availability](#): FreeBSD, NetBSD  $\geq$  7, OpenBSD.

*New in version 3.7.*

time.CLOCK\_TAI

[International Atomic Time](#) [<https://www.nist.gov/pml/time-and-frequency-division/nist-time-frequently-asked-questions-faq#tai>]

The system must have a current leap second table in order for this to give the correct answer. PTP or NTP software can maintain a leap second table.

[Availability](#): Linux.

*New in version 3.9.*

time.CLOCK\_THREAD\_CPUTIME\_ID

Thread-specific CPU-time clock.

[Availability](#): Unix.

*New in version 3.3.*

`time.CLOCK_UPTIME`

Time whose absolute value is the time the system has been running and not suspended, providing accurate uptime measurement, both absolute and interval.

**Availability:** FreeBSD, OpenBSD  $\geq 5.5$ .

*New in version 3.7.*

`time.CLOCK_UPTIME_RAW`

Clock that increments monotonically, tracking the time since an arbitrary point, unaffected by frequency or time adjustments and not incremented while the system is asleep.

**Availability:** macOS  $\geq 10.12$ .

*New in version 3.8.*

The following constant is the only parameter that can be sent to `clock_settime()`.

`time.CLOCK_REALTIME`

System-wide real-time clock. Setting this clock requires appropriate privileges.

**Availability:** Unix.

*New in version 3.3.*

## Timezone Constants

`time.altzone`

The offset of the local DST timezone, in seconds west of UTC, if one is defined. This is negative if the local DST timezone is east of UTC (as in Western Europe, including the UK). Only use this if `daylight` is nonzero. See note below.

`time.daylight`

Nonzero if a DST timezone is defined. See note below.

`time.timezone`

The offset of the local (non-DST) timezone, in seconds west of UTC (negative in most of Western Europe, positive in the US, zero in the UK). See note below.

`time.tzname`

A tuple of two strings: the first is the name of the local non-DST timezone, the second is the name of the local DST timezone. If no DST timezone is defined, the second string should not be used. See note below.

## Note

For the above Timezone constants (`altzone`, `daylight`, `timezone`, and `tzname`), the value is determined by the timezone rules in effect at module load time or the last time `tzset()` is called and may be incorrect for times in the past. It is recommended to use the `tm_gmtoff` and `tm_zone` results from `localtime()` to obtain timezone information.

## See also

### Module `datetime`

More object-oriented interface to dates and times.

### Module `locale`

Internationalization services. The locale setting affects the interpretation of many format specifiers in `strftime()` and `strptime()`.

### Module `calendar`

General calendar-related functions. `timegm()` is the inverse of `gmtime()` from this module.

## Footnotes

1(**1,2,3**)

The use of `%Z` is now deprecated, but the `%z` escape that expands to the preferred hour/minute offset is not supported by all ANSI C libraries. Also, a strict reading of the original 1982 **RFC 822** [<https://datatracker.ietf.org/doc/html/rfc822.html>] standard calls for a two-digit year (`%y` rather than `%Y`), but practice moved to 4-digit years long before the year 2000. After that, **RFC 822** [<https://datatracker.ietf.org/doc/html/rfc822.html>] became obsolete and the 4-digit year has been first recommended by **RFC 1123** [<https://datatracker.ietf.org/doc/html/rfc1123.html>] and then mandated by **RFC 2822** [<https://datatracker.ietf.org/doc/html/rfc2822.html>].

# **argparse** — Parser for command-line options, arguments and sub-commands

*New in version 3.2.*

**Source code:** [Lib/argparse.py](https://github.com/python/cpython/tree/3.11/Lib/argparse.py) [https://github.com/python/cpython/tree/3.11/Lib/argparse.py]

---

## **Tutorial**

This page contains the API reference information. For a more gentle introduction to Python command-line parsing, have a look at the [argparse tutorial](#).

The **argparse** module makes it easy to write user-friendly command-line interfaces. The program defines what arguments it requires, and **argparse** will figure out how to parse those out of **sys.argv**. The **argparse** module also automatically generates help and usage messages. The module will also issue errors when users give the program invalid arguments.

## **Core Functionality**

The **argparse** module's support for command-line interfaces is built around an instance of **argparse.ArgumentParser**. It is a container for argument specifications and has options that apply the parser as whole:

```
parser = argparse.ArgumentParser(  
    prog='ProgramName',  
    description='What the program does',  
    epilog='Text at the bottom of help')
```

The `ArgumentParser.add_argument()` method attaches individual argument specifications to the parser. It supports positional arguments, options that accept values, and on/off flags:

```
parser.add_argument('filename')           # positional argument
parser.add_argument('-c', '--count')      # option that takes a value
parser.add_argument('-v', '--verbose',    # on/off flag
                    action='store_true')
```

The `ArgumentParser.parse_args()` method runs the parser and places the extracted data in a `argparse.Namespace` object:

```
args = parser.parse_args()
print(args.filename, args.count, args.verbose)
```

## Quick Links for add\_argument()

### Namespacing

**Specify how an argument should be handled**, 'append', 'append\_const', 'count', 'help', 'version'

**Limit values to a specific set of choices** or **Container** instance

**Store** a constant value

**Default value** used when an argument is not provided

**Specify the attribute name** used in the result namespace

**Help** message for an argument

**Alternate display name** for the argument as shown in help

**Number of times** the argument can be used

**Indicate whether** an argument is required or optional

**Automatically convert** an argument to the given type or function

## Example

The following code is a Python program that takes a list of integers and produces either the sum or the max:

```
import argparse
```

```
parser = argparse.ArgumentParser(description='Process some integers')
parser.add_argument('integers', metavar='N', type=int, n
```

```

        help='an integer for the accumulator
parser.add_argument('--sum', dest='accumulate', action='
        const=sum, default=max,
        help='sum the integers (default: find the max)')

args = parser.parse_args()
print(args.accumulate(args.integers))

```

Assuming the above Python code is saved into a file called `prog.py`, it can be run at the command line and it provides useful help messages:

```

$ python prog.py -h
usage: prog.py [-h] [--sum] N [N ...]

```

Process some integers.

positional arguments:

```

  N                an integer for the accumulator

```

options:

```

  -h, --help  show this help message and exit
  --sum       sum the integers (default: find the max)

```

When run with the appropriate arguments, it prints either the sum or the max of the command-line integers:

```

$ python prog.py 1 2 3 4
4

```

```

$ python prog.py 1 2 3 4 --sum
10

```

If invalid arguments are passed in, an error will be displayed:

```

$ python prog.py a b c
usage: prog.py [-h] [--sum] N [N ...]
prog.py: error: argument N: invalid int value: 'a'

```

The following sections walk you through this example.

## Creating a parser

The first step in using the `argparse` is creating an `ArgumentParser` object:

```
>>> parser = argparse.ArgumentParser(description='Process some inputs')
```

The `ArgumentParser` object will hold all the information necessary to parse the command line into Python data types.

## Adding arguments

Filling an `ArgumentParser` with information about program arguments is done by making calls to the `add_argument()` method. Generally, these calls tell the `ArgumentParser` how to take the strings on the command line and turn them into objects. This information is stored and used when `parse_args()` is called. For example:

```
>>> parser.add_argument('integers', metavar='N', type=int,
...                     help='an integer for the accumulator')
>>> parser.add_argument('--sum', dest='accumulate', action='store_true',
...                     const=sum, default=max,
...                     help='sum the integers (default: max)')
```

Later, calling `parse_args()` will return an object with two attributes, `integers` and `accumulate`. The `integers` attribute will be a list of one or more integers, and the `accumulate` attribute will be either the `sum()` function, if `--sum` was specified at the command line, or the `max()` function if it was not.

## Parsing arguments

`ArgumentParser` parses arguments through the `parse_args()` method. This will inspect the command line, convert each argument to the appropriate type and then invoke the appropriate action. In most cases, this means a simple `Namespace` object will be built up from attributes parsed out of the command line:

```
>>> parser.parse_args(['--sum', '7', '-1', '42'])
```

Namespace(accumulate=<built-in function sum>, integers=)

In a script, `parse_args()` will typically be called with no arguments, and the `ArgumentParser` will automatically determine the command-line arguments from `sys.argv`.

## ArgumentParser objects

```
class argparse.ArgumentParser(prog=None, usage=None,
description=None, epilog=None, parents=[],
formatter_class=argparse.HelpFormatter, prefix_chars='-',
fromfile_prefix_chars=None, argument_default=None,
conflict_handler='error', add_help=True, allow_abbrev=True,
exit_on_error=True)
```

Create a new `ArgumentParser` object. All parameters should be passed as keyword arguments. Each parameter has its own more detailed description below, but in short they are:

- `prog` - The name of the program (default: `os.path.basename(sys.argv[0])`)
- `usage` - The string describing the program usage (default: generated from arguments added to parser)
- `description` - Text to display before the argument help (by default, no text)
- `epilog` - Text to display after the argument help (by default, no text)
- `parents` - A list of `ArgumentParser` objects whose arguments should also be included
- `formatter_class` - A class for customizing the help output
- `prefix_chars` - The set of characters that prefix optional arguments (default: `'-'`)
- `fromfile_prefix_chars` - The set of characters that prefix files from which additional arguments should be read (default: `None`)
- `argument_default` - The global default value for arguments (default: `None`)
- `conflict_handler` - The strategy for resolving conflicting optionals (usually unnecessary)

- [add\\_help](#) - Add a `-h/--help` option to the parser (default: `True`)
- [allow\\_abbrev](#) - Allows long options to be abbreviated if the abbreviation is unambiguous. (default: `True`)
- [exit\\_on\\_error](#) - Determines whether or not `ArgumentParser` exits with error info when an error occurs. (default: `True`)

*Changed in version 3.5:* `allow_abbrev` parameter was added.

*Changed in version 3.8:* In previous versions, `allow_abbrev` also disabled grouping of short flags such as `-vv` to mean `-v -v`.

*Changed in version 3.9:* `exit_on_error` parameter was added.

The following sections describe how each of these are used.

## prog

By default, [ArgumentParser](#) objects use `sys.argv[0]` to determine how to display the name of the program in help messages. This default is almost always desirable because it will make the help messages match how the program was invoked on the command line. For example, consider a file named `myprogram.py` with the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

The help for this program will display `myprogram.py` as the program name (regardless of where the program was invoked from):

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]
```

options:

```
-h, --help  show this help message and exit
--foo FOO   foo help
$ cd ..
$ python subdir/myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]
```

options:

```
-h, --help  show this help message and exit
--foo FOO   foo help
```

To change this default behavior, another value can be supplied using the `prog=` argument to [ArgumentParser](#):

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.print_help()
usage: myprogram [-h]
```

options:

```
-h, --help  show this help message and exit
```

Note that the program name, whether determined from `sys.argv[0]` or from the `prog=` argument, is available to help messages using the `%(prog)s` format specifier.

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.add_argument('--foo', help='foo of the %(prog)s')
>>> parser.print_help()
usage: myprogram [-h] [--foo FOO]
```

options:

```
-h, --help  show this help message and exit
--foo FOO   foo of the myprogram program
```

## usage

By default, [ArgumentParser](#) calculates the usage message from the arguments it contains:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', nargs='?', help='foo he
```

```
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [-h] [--foo [FOO]] bar [bar ...]
```

```
positional arguments:
  bar                  bar help
```

```
options:
  -h, --help          show this help message and exit
  --foo [FOO]         foo help
```

The default message can be overridden with the `usage=` keyword argument:

```
>>> parser = argparse.ArgumentParser(prog='PROG', usage=
>>> parser.add_argument('--foo', nargs='?', help='foo he
>>> parser.add_argument('bar', nargs='+', help='bar help
>>> parser.print_help()
usage: PROG [options]
```

```
positional arguments:
  bar                  bar help
```

```
options:
  -h, --help          show this help message and exit
  --foo [FOO]         foo help
```

The `%(prog)s` format specifier is available to fill in the program name in your usage messages.

## description

Most calls to the `ArgumentParser` constructor will use the `description=` keyword argument. This argument gives a brief description of what the program does and how it works. In help messages, the description is displayed between the command-line usage string and the help messages for the various arguments:

```
>>> parser = argparse.ArgumentParser(description='A foo
>>> parser.print_help()
```

```
usage: argparse.py [-h]
```

```
A foo that bars
```

```
options:
```

```
-h, --help  show this help message and exit
```

By default, the description will be line-wrapped so that it fits within the given space. To change this behavior, see the [formatter\\_class](#) argument.

## epilog

Some programs like to display additional description of the program after the description of the arguments. Such text can be specified using the `epilog=` argument to [ArgumentParser](#):

```
>>> parser = argparse.ArgumentParser(
...     description='A foo that bars',
...     epilog="And that's how you'd foo a bar")
>>> parser.print_help()
usage: argparse.py [-h]
```

```
A foo that bars
```

```
options:
```

```
-h, --help  show this help message and exit
```

```
And that's how you'd foo a bar
```

As with the [description](#) argument, the `epilog=` text is by default line-wrapped, but this behavior can be adjusted with the [formatter\\_class](#) argument to [ArgumentParser](#).

## parents

Sometimes, several parsers share a common set of arguments. Rather than repeating the definitions of these arguments, a single parser with all the shared arguments and passed to `parents=`

argument to **ArgumentParser** can be used. The `parents=` argument takes a list of **ArgumentParser** objects, collects all the positional and optional actions from them, and adds these actions to the **ArgumentParser** object being constructed:

```
>>> parent_parser = argparse.ArgumentParser(add_help=False)
>>> parent_parser.add_argument('--parent', type=int)

>>> foo_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> foo_parser.add_argument('foo')
>>> foo_parser.parse_args(['--parent', '2', 'XXX'])
Namespace(foo='XXX', parent=2)

>>> bar_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> bar_parser.add_argument('--bar')
>>> bar_parser.parse_args(['--bar', 'YYY'])
Namespace(bar='YYY', parent=None)
```

Note that most parent parsers will specify `add_help=False`. Otherwise, the **ArgumentParser** will see two `-h/--help` options (one in the parent and one in the child) and raise an error.

## Note

You must fully initialize the parsers before passing them via `parents=`. If you change the parent parsers after the child parser, those changes will not be reflected in the child.

## formatter\_class

**ArgumentParser** objects allow the help formatting to be customized by specifying an alternate formatting class. Currently, there are four such classes:

```
class argparse.RawDescriptionHelpFormatter
class argparse.RawTextHelpFormatter
class argparse.ArgumentDefaultsHelpFormatter
class argparse.MetavarTypeHelpFormatter
```

**RawDescriptionHelpFormatter** and **RawTextHelpFormatter** give more control over how textual descriptions are displayed. By default, **ArgumentParser** objects line-wrap the **description** and **epilog** texts in command-line help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     description='''this description
...         was indented weird
...         but that is okay''',
...     epilog='''
...         likewise for this epilog whose whitespace
...         be cleaned up and whose words will be wrapped
...         across a couple lines''')
>>> parser.print_help()
usage: PROG [-h]
```

this description was indented weird but that is okay

options:

-h, --help show this help message and exit

likewise for this epilog whose whitespace will be cleaned up and whose words will be wrapped across a couple lines

Passing **RawDescriptionHelpFormatter** as `formatter_class=` indicates that **description** and **epilog** are already correctly formatted and should not be line-wrapped:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.RawDescriptionHelpFormatter,
...     description=textwrap.dedent('''\
...         Please do not mess up this text!
...         -----
...         I have indented it
...         exactly the way
...         I want it
...     '''))
```

```
...         ''')
>>> parser.print_help()
usage: PROG [-h]
```

Please do not mess up this text!

```
-----
    I have indented it
    exactly the way
    I want it
```

options:

-h, --help show this help message and exit

**RawTextHelpFormatter** maintains whitespace for all sorts of help text, including argument descriptions. However, multiple new lines are replaced with one. If you wish to preserve multiple blank lines, add spaces between the newlines.

**ArgumentDefaultsHelpFormatter** automatically adds information about default values to each of the argument help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.ArgumentDefaultsHelpFor
>>> parser.add_argument('--foo', type=int, default=42, h
>>> parser.add_argument('bar', nargs='*', default=[1, 2,
>>> parser.print_help()
usage: PROG [-h] [--foo FOO] [bar ...]
```

positional arguments:

bar BAR! (default: [1, 2, 3])

options:

-h, --help show this help message and exit  
--foo FOO FOO! (default: 42)

**MetavarTypeHelpFormatter** uses the name of the **type** argument for each argument as the display name for its values (rather than using the **dest** as the regular formatter does):

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.MetavarTypeHelpFormatter)
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', type=float)
>>> parser.print_help()
usage: PROG [-h] [--foo int] float
```

```
positional arguments:
  float
```

```
options:
  -h, --help  show this help message and exit
  --foo int
```

## prefix\_chars

Most command-line options will use `-` as the prefix, e.g. `-f/--foo`. Parsers that need to support different or additional prefix characters, e.g. for options like `+f` or `/foo`, may specify them using the `prefix_chars=` argument to the `ArgumentParser` constructor:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='+/')
>>> parser.add_argument('+f')
>>> parser.add_argument('++bar')
>>> parser.parse_args('+f X ++bar Y'.split())
Namespace(bar='Y', f='X')
```

The `prefix_chars=` argument defaults to `'-'`. Supplying a set of characters that does not include `-` will cause `-f/--foo` options to be disallowed.

## fromfile\_prefix\_chars

Sometimes, when dealing with a particularly long argument list, it may make sense to keep the list of arguments in a file rather than typing it out at the command line. If the `fromfile_prefix_chars=` argument is given to the

**ArgumentParser** constructor, then arguments that start with any of the specified characters will be treated as files, and will be replaced by the arguments they contain. For example:

```
>>> with open('args.txt', 'w') as fp:
...     fp.write('-f\nbar')
>>> parser = argparse.ArgumentParser(fromfile_prefix_chars='@')
>>> parser.add_argument('-f')
>>> parser.parse_args(['-f', 'foo', '@args.txt'])
Namespace(f='bar')
```

Arguments read from a file must by default be one per line (but see also [convert\\_arg\\_line\\_to\\_args\(\)](#)) and are treated as if they were in the same place as the original file referencing argument on the command line. So in the example above, the expression `['-f', 'foo', '@args.txt']` is considered equivalent to the expression `['-f', 'foo', '-f', 'bar']`.

The `fromfile_prefix_chars=` argument defaults to `None`, meaning that arguments will never be treated as file references.

## argument\_default

Generally, argument defaults are specified either by passing a default to [add\\_argument\(\)](#) or by calling the [set\\_defaults\(\)](#) methods with a specific set of name-value pairs. Sometimes however, it may be useful to specify a single parser-wide default for arguments. This can be accomplished by passing the `argument_default=` keyword argument to [ArgumentParser](#). For example, to globally suppress attribute creation on [parse\\_args\(\)](#) calls, we supply `argument_default=SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(argument_default=argparse.SUPPRESS)
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar', nargs='?')
>>> parser.parse_args(['--foo', '1', 'BAR'])
Namespace(bar='BAR', foo='1')
>>> parser.parse_args([])
Namespace()
```

## allow\_abbrev

Normally, when you pass an argument list to the `parse_args()` method of an `ArgumentParser`, it recognizes abbreviations of long options.

This feature can be disabled by setting `allow_abbrev` to `False`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', allow_abbrev=False)
>>> parser.add_argument('--foobar', action='store_true')
>>> parser.add_argument('--foonley', action='store_false')
>>> parser.parse_args(['--foon'])
usage: PROG [-h] [--foobar] [--foonley]
PROG: error: unrecognized arguments: --foon
```

*New in version 3.5.*

## conflict\_handler

`ArgumentParser` objects do not allow two actions with the same option string. By default, `ArgumentParser` objects raise an exception if an attempt is made to create an argument with an option string that is already in use:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
Traceback (most recent call last):
..
ArgumentError: argument --foo: conflicting option string
```

Sometimes (e.g. when using [parents](#)) it may be useful to simply override any older arguments with the same option string. To get this behavior, the value `'resolve'` can be supplied to the `conflict_handler=` argument of `ArgumentParser`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', conflict_handler='resolve')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
>>> parser.print_help()
```

```
usage: PROG [-h] [-f FOO] [--foo FOO]
```

```
options:
```

```
-h, --help  show this help message and exit
-f FOO      old foo help
--foo FOO   new foo help
```

Note that **ArgumentParser** objects only remove an action if all of its option strings are overridden. So, in the example above, the old `-f/--foo` action is retained as the `-f` action, because only the `--foo` option string was overridden.

## add\_help

By default, **ArgumentParser** objects add an option which simply displays the parser's help message. For example, consider a file named `myprogram.py` containing the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

If `-h` or `--help` is supplied at the command line, the **ArgumentParser** help will be printed:

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]
```

```
options:
```

```
-h, --help  show this help message and exit
--foo FOO   foo help
```

Occasionally, it may be useful to disable the addition of this help option. This can be achieved by passing `False` as the `add_help=` argument to **ArgumentParser**:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> parser.add_argument('--foo', help='foo help')
>>> parser.print_help()
```

```
usage: PROG [--foo FOO]
```

```
options:
```

```
--foo FOO  foo help
```

The help option is typically `-h/--help`. The exception to this is if the `prefix_chars=` is specified and does not include `-`, in which case `-h` and `--help` are not valid options. In this case, the first character in `prefix_chars` is used to prefix the help options:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='+')
>>> parser.print_help()
usage: PROG [+h]
```

```
options:
```

```
+h, ++help  show this help message and exit
```

## **exit\_on\_error**

Normally, when you pass an invalid argument list to the `parse_args()` method of an `ArgumentParser`, it will exit with error info.

If the user would like to catch errors manually, the feature can be enabled by setting `exit_on_error` to `False`:

```
>>> parser = argparse.ArgumentParser(exit_on_error=False)
>>> parser.add_argument('--integers', type=int)
... _StoreAction(option_strings=['--integers'], dest='integers', nargs='*',
... try:
...     parser.parse_args('--integers a'.split())
... except argparse.ArgumentError:
...     print('Catching an argumentError')
...
Catching an argumentError
```

*New in version 3.9.*

## **The add\_argument() method**

```
ArgumentParser.add_argument(name or flags... [, action] [, nargs] [,  
const] [, default] [, type] [, choices] [, required] [, help] [, metavar] [,  
dest])
```

Define how a single command-line argument should be parsed. Each parameter has its own more detailed description below, but in short they are:

- **name or flags** - Either a name or a list of option strings, e.g. `foo` or `-f`, `--foo`.
- **action** - The basic type of action to be taken when this argument is encountered at the command line.
- **nargs** - The number of command-line arguments that should be consumed.
- **const** - A constant value required by some **action** and **nargs** selections.
- **default** - The value produced if the argument is absent from the command line and if it is absent from the namespace object.
- **type** - The type to which the command-line argument should be converted.
- **choices** - A sequence of the allowable values for the argument.
- **required** - Whether or not the command-line option may be omitted (optionals only).
- **help** - A brief description of what the argument does.
- **metavar** - A name for the argument in usage messages.
- **dest** - The name of the attribute to be added to the object returned by **parse\_args()**.

The following sections describe how each of these are used.

## name or flags

The **add\_argument()** method must know whether an optional argument, like `-f` or `--foo`, or a positional argument, like a list of filenames, is expected. The first arguments passed to **add\_argument()** must therefore be either a series of flags, or a simple argument name.

For example, an optional argument could be created like:

```
>>> parser.add_argument('-f', '--foo')
```

while a positional argument could be created like:

```
>>> parser.add_argument('bar')
```

When `parse_args()` is called, optional arguments will be identified by the `-` prefix, and the remaining arguments will be assumed to be positional:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args(['BAR'])
Namespace(bar='BAR', foo=None)
>>> parser.parse_args(['BAR', '--foo', 'FOO'])
Namespace(bar='BAR', foo='FOO')
>>> parser.parse_args(['--foo', 'FOO'])
usage: PROG [-h] [-f FOO] bar
PROG: error: the following arguments are required: bar
```

## action

`ArgumentParser` objects associate command-line arguments with actions. These actions can do just about anything with the command-line arguments associated with them, though most actions simply add an attribute to the object returned by `parse_args()`. The `action` keyword argument specifies how the command-line arguments should be handled. The supplied actions are:

- `'store'` - This just stores the argument's value. This is the default action. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args('--foo 1'.split())
Namespace(foo='1')
```

- `'store_const'` - This stores the value specified by the `const` keyword argument; note that the `const` keyword argument defaults to `None`. The `'store_const'` action is most commonly used with optional arguments that specify some sort of flag. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_const')
>>> parser.parse_args(['--foo'])
Namespace(foo=42)
```

- `'store_true'` and `'store_false'` - These are special cases of `'store_const'` used for storing the values `True` and `False` respectively. In addition, they create default values of `False` and `True` respectively. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('--bar', action='store_false')
>>> parser.add_argument('--baz', action='store_false')
>>> parser.parse_args('--foo --bar'.split())
Namespace(foo=True, bar=False, baz=True)
```

- `'append'` - This stores a list, and appends each argument value to the list. It is useful to allow an option to be specified multiple times. If the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values. Example usage:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='append')
>>> parser.parse_args('--foo 1 --foo 2'.split())
Namespace(foo=['1', '2'])
```

- `'append_const'` - This stores a list, and appends the value specified by the `const` keyword argument to the list; note that the `const` keyword argument defaults to `None`. The `'append_const'` action is typically useful when multiple arguments need to store constants to the same list. For

example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--str', dest='types', action='append')
>>> parser.add_argument('--int', dest='types', action='append')
>>> parser.parse_args('--str --int'.split())
Namespace(types=[<class 'str'>, <class 'int'>])
```

- 'count' - This counts the number of times a keyword argument occurs. For example, this is useful for increasing verbosity levels:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--verbose', '-v', action='count')
>>> parser.parse_args(['-vvv'])
Namespace(verbose=3)
```

Note, the *default* will be `None` unless explicitly set to `0`.

- 'help' - This prints a complete help message for all the options in the current parser and then exits. By default a help action is automatically added to the parser. See [ArgumentParser](#) for details of how the output is created.
- 'version' - This expects a `version=` keyword argument in the `add_argument()` call, and prints version information and exits when invoked:

```
>>> import argparse
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--version', action='version')
>>> parser.parse_args(['--version'])
PROG 2.0
```

- 'extend' - This stores a list, and extends each argument value to the list. Example usage:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument("--foo", action="extend", nargs="*")
>>> parser.parse_args(["--foo", "f1", "--foo", "f2"])
Namespace(foo=['f1', 'f2', 'f3', 'f4'])
```

### *New in version 3.8.*

You may also specify an arbitrary action by passing an `Action` subclass or other object that implements the same interface. The `BooleanOptionalAction` is available in `argparse` and adds support for boolean actions such as `--foo` and `--no-foo`:

```
>>> import argparse
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=argparse.BooleanOptionalAction)
>>> parser.parse_args(['--no-foo'])
Namespace(foo=False)
```

### *New in version 3.9.*

The recommended way to create a custom action is to extend `Action`, overriding the `__call__` method and optionally the `__init__` and `format_usage` methods.

An example of a custom action:

```
>>> class FooAction(argparse.Action):
...     def __init__(self, option_strings, dest, nargs=None, **kwargs):
...         if nargs is not None:
...             raise ValueError("nargs not allowed")
...         super().__init__(option_strings, dest, **kwargs)
...     def __call__(self, parser, namespace, values, option_string=None):
...         print('%r %r %r' % (namespace, values, option_string))
...         setattr(namespace, self.dest, values)
...
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=FooAction)
>>> parser.add_argument('bar', action=FooAction)
>>> args = parser.parse_args('1 --foo 2'.split())
Namespace(bar=None, foo=None) '1' None
Namespace(bar='1', foo=None) '2' '--foo'
>>> args
Namespace(bar='1', foo='2')
```

For more details, see [Action](#).

## nargs

ArgumentParser objects usually associate a single command-line argument with a single action to be taken. The `nargs` keyword argument associates a different number of command-line arguments with a single action. The supported values are:

- `N` (an integer). `N` arguments from the command line will be gathered together into a list. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs=2)
>>> parser.add_argument('bar', nargs=1)
>>> parser.parse_args('c --foo a b'.split())
Namespace(bar=['c'], foo=['a', 'b'])
```

Note that `nargs=1` produces a list of one item. This is different from the default, in which the item is produced by itself.

- `'?'`. One argument will be consumed from the command line if possible, and produced as a single item. If no command-line argument is present, the value from `default` will be produced. Note that for optional arguments, there is an additional case - the option string is present but not followed by a command-line argument. In this case the value from `const` will be produced. Some examples to illustrate this:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='?', const='c')
>>> parser.add_argument('bar', nargs='?', default='d')
>>> parser.parse_args(['XX', '--foo', 'YY'])
Namespace(bar='XX', foo='YY')
>>> parser.parse_args(['XX', '--foo'])
Namespace(bar='XX', foo='c')
>>> parser.parse_args([])
Namespace(bar='d', foo='d')
```

One of the more common uses of `nargs='?'` is to allow optional input and output files:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', nargs='?', type=argparse.FileType('r'),
...                     default=sys.stdin)
>>> parser.add_argument('outfile', nargs='?', type=argparse.FileType('w'),
...                     default=sys.stdout)
>>> parser.parse_args(['input.txt', 'output.txt'])
Namespace(infile=<_io.TextIOWrapper name='input.txt' mode='r' encoding='utf-8'>,
          outfile=<_io.TextIOWrapper name='output.txt' mode='w' encoding='utf-8'>)
>>> parser.parse_args([])
Namespace(infile=<_io.TextIOWrapper name='<stdin>' mode='r' encoding='utf-8'>,
          outfile=<_io.TextIOWrapper name='<stdout>' mode='w' encoding='utf-8'>)
```

- `*`. All command-line arguments present are gathered into a list. Note that it generally doesn't make much sense to have more than one positional argument with `nargs='*'`, but multiple optional arguments with `nargs='*'` is possible. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='*')
>>> parser.add_argument('--bar', nargs='*')
>>> parser.add_argument('baz', nargs='*')
>>> parser.parse_args('a b --foo x y --bar 1 2'.split())
Namespace(bar=['1', '2'], baz=['a', 'b'], foo=['x', 'y'])
```

- `+`. Just like `*`, all command-line args present are gathered into a list. Additionally, an error message will be generated if there wasn't at least one command-line argument present. For example:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', nargs='+')
>>> parser.parse_args(['a', 'b'])
Namespace(foo=['a', 'b'])
>>> parser.parse_args([])
usage: PROG [-h] foo [foo ...]
PROG: error: the following arguments are required: foo
```

If the `nargs` keyword argument is not provided, the number of arguments consumed is determined by the [action](#). Generally this

means a single command-line argument will be consumed and a single item (not a list) will be produced.

## const

The `const` argument of `add_argument()` is used to hold constant values that are not read from the command line but are required for the various `ArgumentParser` actions. The two most common uses of it are:

- When `add_argument()` is called with `action='store_const'` or `action='append_const'`. These actions add the `const` value to one of the attributes of the object returned by `parse_args()`. See the `action` description for examples. If `const` is not provided to `add_argument()`, it will receive a default value of `None`.
- When `add_argument()` is called with option strings (like `-f` or `--foo`) and `nargs='?'`. This creates an optional argument that can be followed by zero or one command-line arguments. When parsing the command line, if the option string is encountered with no command-line argument following it, the value of `const` will be assumed to be `None` instead. See the `nargs` description for examples.

*Changed in version 3.11:* `const=None` by default, including when `action='append_const'` or `action='store_const'`.

## default

All optional arguments and some positional arguments may be omitted at the command line. The `default` keyword argument of `add_argument()`, whose value defaults to `None`, specifies what value should be used if the command-line argument is not present. For optional arguments, the `default` value is used when the option string was not present at the command line:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args(['--foo', '2'])
Namespace(foo='2')
```

```
>>> parser.parse_args([])
Namespace(foo=42)
```

If the target namespace already has an attribute set, the action *default* will not over write it:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args([], namespace=argparse.Namespace(f
Namespace(foo=101)
```

If the default value is a string, the parser parses the value as if it were a command-line argument. In particular, the parser applies any [type](#) conversion argument, if provided, before setting the attribute on the [Namespace](#) return value. Otherwise, the parser uses the value as is:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--length', default='10', type=int)
>>> parser.add_argument('--width', default=10.5, type=float)
>>> parser.parse_args()
Namespace(length=10, width=10.5)
```

For positional arguments with [nargs](#) equal to `?` or `*`, the default value is used when no command-line argument was present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', nargs='?', default=42)
>>> parser.parse_args(['a'])
Namespace(foo='a')
>>> parser.parse_args([])
Namespace(foo=42)
```

Providing `default=argparse.SUPPRESS` causes no attribute to be added if the command-line argument was not present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=argparse.SUPPRESS)
>>> parser.parse_args([])
Namespace()
```

```
>>> parser.parse_args(['--foo', '1'])
Namespace(foo='1')
```

## type

By default, the parser reads command-line arguments in as simple strings. However, quite often the command-line string should instead be interpreted as another type, such as a `float` or `int`. The `type` keyword for `add_argument()` allows any necessary type-checking and type conversions to be performed.

If the `type` keyword is used with the `default` keyword, the type converter is only applied if the default is a string.

The argument to `type` can be any callable that accepts a single string. If the function raises `ArgumentTypeError`, `TypeError`, or `ValueError`, the exception is caught and a nicely formatted error message is displayed. No other exception types are handled.

Common built-in types and functions can be used as type converters:

```
import argparse
import pathlib
```

```
parser = argparse.ArgumentParser()
parser.add_argument('count', type=int)
parser.add_argument('distance', type=float)
parser.add_argument('street', type=ascii)
parser.add_argument('code_point', type=ord)
parser.add_argument('source_file', type=open)
parser.add_argument('dest_file', type=argparse.FileType('r'))
parser.add_argument('datapath', type=pathlib.Path)
```

User defined functions can be used as well:

```
>>> def hyphenated(string):
...     return '-'.join([word[:4] for word in string.split()])
...
>>> parser = argparse.ArgumentParser()
```

```
>>> _ = parser.add_argument('short_title', type=hyphenate)
>>> parser.parse_args(['"The Tale of Two Cities"'])
Namespace(short_title='"the-tale-of-two-citi"')
```

The `bool()` function is not recommended as a type converter. All it does is convert empty strings to `False` and non-empty strings to `True`. This is usually not what is desired.

In general, the `type` keyword is a convenience that should only be used for simple conversions that can only raise one of the three supported exceptions. Anything with more interesting error-handling or resource management should be done downstream after the arguments are parsed.

For example, JSON or YAML conversions have complex error cases that require better reporting than can be given by the `type` keyword. A `JSONDecodeError` would not be well formatted and a `FileNotFoundError` exception would not be handled at all.

Even `FileType` has its limitations for use with the `type` keyword. If one argument uses `FileType` and then a subsequent argument fails, an error is reported but the file is not automatically closed. In this case, it would be better to wait until after the parser has run and then use the `with`-statement to manage the files.

For type checkers that simply check against a fixed set of values, consider using the `choices` keyword instead.

## choices

Some command-line arguments should be selected from a restricted set of values. These can be handled by passing a sequence object as the *choices* keyword argument to `add_argument()`. When the command line is parsed, argument values will be checked, and an error message will be displayed if the argument was not one of the acceptable values:

```
>>> parser = argparse.ArgumentParser(prog='game.py')
>>> parser.add_argument('move', choices=['rock', 'paper'])
>>> parser.parse_args(['rock'])
Namespace(move='rock')
```

```
>>> parser.parse_args(['fire'])
usage: game.py [-h] {rock,paper,scissors}
game.py: error: argument move: invalid choice: 'fire' (choices:
'paper', 'scissors')
```

Note that inclusion in the *choices* sequence is checked after any [type](#) conversions have been performed, so the type of the objects in the *choices* sequence should match the [type](#) specified:

```
>>> parser = argparse.ArgumentParser(prog='doors.py')
>>> parser.add_argument('door', type=int, choices=range(1,4))
>>> print(parser.parse_args(['3']))
Namespace(door=3)
>>> parser.parse_args(['4'])
usage: doors.py [-h] {1,2,3}
doors.py: error: argument door: invalid choice: 4 (choices: 1, 2, 3)
```

Any sequence can be passed as the *choices* value, so [list](#) objects, [tuple](#) objects, and custom sequences are all supported.

Use of [enum.Enum](#) is not recommended because it is difficult to control its appearance in usage, help, and error messages.

Formatted choices override the default *metavar* which is normally derived from *dest*. This is usually what you want because the user never sees the *dest* parameter. If this display isn't desirable (perhaps because there are many choices), just specify an explicit [metavar](#).

## required

In general, the [argparse](#) module assumes that flags like `-f` and `--bar` indicate *optional* arguments, which can always be omitted at the command line. To make an option *required*, `True` can be specified for the `required=` keyword argument to [add\\_argument\(\)](#):

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', required=True)
>>> parser.parse_args(['--foo', 'BAR'])
Namespace(foo='BAR')
```

```
>>> parser.parse_args([])
usage: [-h] --foo FOO
: error: the following arguments are required: --foo
```

As the example shows, if an option is marked as `required`, `parse_args()` will report an error if that option is not present at the command line.

## Note

Required options are generally considered bad form because users expect *options* to be *optional*, and thus they should be avoided when possible.

## help

The `help` value is a string containing a brief description of the argument. When a user requests help (usually by using `-h` or `--help` at the command line), these `help` descriptions will be displayed with each argument:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', action='store_true',
...                      help='foo the bars before frobbing')
>>> parser.add_argument('bar', nargs='+',
...                      help='one of the bars to be frobbled')
>>> parser.parse_args(['-h'])
usage: frobble [-h] [--foo] bar [bar ...]
```

positional arguments:

bar            one of the bars to be frobbled

options:

-h, --help    show this help message and exit  
--foo        foo the bars before frobbing

The `help` strings can include various format specifiers to avoid repetition of things like the program name or the argument `default`. The available specifiers include the program name, `%(prog)s` and

most keyword arguments to `add_argument()`, e.g.

`%(default)s`, `%(type)s`, etc.:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('bar', nargs='?', type=int, default=42,
...                     help='the bar to %(prog)s (default: 42)')
>>> parser.print_help()
usage: frobble [-h] [bar]
```

positional arguments:

bar the bar to frobble (default: 42)

options:

-h, --help show this help message and exit

As the help string supports %-formatting, if you want a literal `%` to appear in the help string, you must escape it as `%%`.

`argparse` supports silencing the help entry for certain options, by setting the `help` value to `argparse.SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', help=argparse.SUPPRESS)
>>> parser.print_help()
usage: frobble [-h]
```

options:

-h, --help show this help message and exit

## metavar

When `ArgumentParser` generates help messages, it needs some way to refer to each expected argument. By default, `ArgumentParser` objects use the `dest` value as the “name” of each object. By default, for positional argument actions, the `dest` value is used directly, and for optional argument actions, the `dest` value is uppercased. So, a single positional argument with `dest='bar'` will be referred to as `bar`. A single optional argument `--foo` that should be followed by a single command-line argument will be referred to as `FOO`. An example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage:  [-h] [--foo FOO] bar

positional arguments:
  bar

options:
  -h, --help  show this help message and exit
  --foo FOO
```

An alternative name can be specified with `metavar`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', metavar='YYY')
>>> parser.add_argument('bar', metavar='XXX')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage:  [-h] [--foo YYY] XXX

positional arguments:
  XXX

options:
  -h, --help  show this help message and exit
  --foo YYY
```

Note that `metavar` only changes the *displayed* name - the name of the attribute on the `parse_args()` object is still determined by the `dest` value.

Different values of `nargs` may cause the `metavar` to be used multiple times. Providing a tuple to `metavar` specifies a different display for each of the arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', nargs=2)
>>> parser.add_argument('--foo', nargs=2, metavar=('bar', 'baz'))
>>> parser.print_help()
usage: PROG [-h] [-x X X] [--foo bar baz]
```

options:

```
-h, --help      show this help message and exit
-x X X
--foo bar baz
```

## dest

Most `ArgumentParser` actions add some value as an attribute of the object returned by `parse_args()`. The name of this attribute is determined by the `dest` keyword argument of `add_argument()`. For positional argument actions, `dest` is normally supplied as the first argument to `add_argument()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar')
>>> parser.parse_args(['XXX'])
Namespace(bar='XXX')
```

For optional argument actions, the value of `dest` is normally inferred from the option strings. `ArgumentParser` generates the value of `dest` by taking the first long option string and stripping away the initial `--` string. If no long option strings were supplied, `dest` will be derived from the first short option string by stripping the initial `-` character. Any internal `-` characters will be converted to `_` characters to make sure the string is a valid attribute name. The examples below illustrate this behavior:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('-f', '--foo-bar', '--foo')
>>> parser.add_argument('-x', '-y')
>>> parser.parse_args('-f 1 -x 2'.split())
Namespace(foo_bar='1', x='2')
>>> parser.parse_args('--foo 1 -y 2'.split())
```

```
Namespace(foo_bar='1', x='2')
```

`dest` allows a custom attribute name to be provided:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', dest='bar')
>>> parser.parse_args('--foo XXX'.split())
Namespace(bar='XXX')
```

## Action classes

Action classes implement the Action API, a callable which returns a callable which processes arguments from the command-line. Any object which follows this API may be passed as the `action` parameter to `add_argument()`.

```
class argparse.Action(option_strings, dest, nargs=None, const=None,
default=None, type=None, choices=None, required=False,
help=None, metavar=None)
```

Action objects are used by an `ArgumentParser` to represent the information needed to parse a single argument from one or more strings from the command line. The Action class must accept the two positional arguments plus any keyword arguments passed to `ArgumentParser.add_argument()` except for the `action` itself.

Instances of Action (or return value of any callable to the `action` parameter) should have attributes “`dest`”, “`option_strings`”, “`default`”, “`type`”, “`required`”, “`help`”, etc. defined. The easiest way to ensure these attributes are defined is to call `Action.__init__`.

Action instances should be callable, so subclasses must override the `__call__` method, which should accept four parameters:

- `parser` - The `ArgumentParser` object which contains this action.
- `namespace` - The `Namespace` object that will be returned by `parse_args()`. Most actions add an attribute to this

object using `setattr()`.

- `values` - The associated command-line arguments, with any type conversions applied. Type conversions are specified with the `type` keyword argument to `add_argument()`.
- `option_string` - The option string that was used to invoke this action. The `option_string` argument is optional, and will be absent if the action is associated with a positional argument.

The `__call__` method may perform arbitrary actions, but will typically set attributes on the `namespace` based on `dest` and `values`.

Action subclasses can define a `format_usage` method that takes no argument and return a string which will be used when printing the usage of the program. If such method is not provided, a sensible default will be used.

## The `parse_args()` method

`ArgumentParser.parse_args(args=None, namespace=None)`

Convert argument strings to objects and assign them as attributes of the namespace. Return the populated namespace.

Previous calls to `add_argument()` determine exactly what objects are created and how they are assigned. See the documentation for `add_argument()` for details.

- `args` - List of strings to parse. The default is taken from `sys.argv`.
- `namespace` - An object to take the attributes. The default is a new empty `Namespace` object.

## Option value syntax

The `parse_args()` method supports several ways of specifying the value of an option (if it takes one). In the simplest case, the option and its value are passed as two separate arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('--foo')
>>> parser.parse_args(['-x', 'X'])
Namespace(foo=None, x='X')
>>> parser.parse_args(['--foo', 'FOO'])
Namespace(foo='FOO', x=None)
```

For long options (options with names longer than a single character), the option and value can also be passed as a single command-line argument, using `=` to separate them:

```
>>> parser.parse_args(['--foo=FOO'])
Namespace(foo='FOO', x=None)
```

For short options (options only one character long), the option and its value can be concatenated:

```
>>> parser.parse_args(['-xX'])
Namespace(foo=None, x='X')
```

Several short options can be joined together, using only a single `-` prefix, as long as only the last option (or none of them) requires a value:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', action='store_true')
>>> parser.add_argument('-y', action='store_true')
>>> parser.add_argument('-z')
>>> parser.parse_args(['-xyzZ'])
Namespace(x=True, y=True, z='Z')
```

## Invalid arguments

While parsing the command line, `parse_args()` checks for a variety of errors, including ambiguous options, invalid types, invalid options, wrong number of positional arguments, etc. When it encounters such an error, it exits and prints the error along with a usage message:

```

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', nargs='?')

>>> # invalid type
>>> parser.parse_args(['--foo', 'spam'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: argument --foo: invalid int value: 'spam'

>>> # invalid option
>>> parser.parse_args(['--bar'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: no such option: --bar

>>> # wrong number of arguments
>>> parser.parse_args(['spam', 'badger'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: extra arguments found: badger

```

## Arguments containing -

The `parse_args()` method attempts to give errors whenever the user has clearly made a mistake, but some situations are inherently ambiguous. For example, the command-line argument `-1` could either be an attempt to specify an option or an attempt to provide a positional argument. The `parse_args()` method is cautious here: positional arguments may only begin with `-` if they look like negative numbers and there are no options in the parser that look like negative numbers:

```

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('foo', nargs='?')

>>> # no negative number options, so -1 is a positional
>>> parser.parse_args(['-x', '-1'])
Namespace(foo=None, x='-1')

>>> # no negative number options, so -1 and -5 are posit

```

```
>>> parser.parse_args(['-x', '-1', '-5'])
Namespace(foo='-5', x='-1')

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-1', dest='one')
>>> parser.add_argument('foo', nargs='?')

>>> # negative number options present, so -1 is an option
>>> parser.parse_args(['-1', 'X'])
Namespace(foo=None, one='X')

>>> # negative number options present, so -2 is an option
>>> parser.parse_args(['-2'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: no such option: -2

>>> # negative number options present, so both -1s are options
>>> parser.parse_args(['-1', '-1'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: argument -1: expected one argument
```

If you have positional arguments that must begin with `-` and don't look like negative numbers, you can insert the pseudo-argument `--` which tells `parse_args()` that everything after that is a positional argument:

```
>>> parser.parse_args(['--', '-f'])
Namespace(foo='-f', one=None)
```

## Argument abbreviations (prefix matching)

The `parse_args()` method by default allows long options to be abbreviated to a prefix, if the abbreviation is unambiguous (the prefix matches a unique option):

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-bacon')
>>> parser.add_argument('-badger')
>>> parser.parse_args('-bac MMM'.split())
```

```

Namespace(bacon='MMM', badger=None)
>>> parser.parse_args('-bad WOOD'.split())
Namespace(bacon=None, badger='WOOD')
>>> parser.parse_args('-ba BA'.split())
usage: PROG [-h] [-bacon BACON] [-badger BADGER]
PROG: error: ambiguous option: -ba could match -badger,

```

An error is produced for arguments that could produce more than one options. This feature can be disabled by setting `allow_abbrev` to `False`.

## Beyond `sys.argv`

Sometimes it may be useful to have an `ArgumentParser` parse arguments other than those of `sys.argv`. This can be accomplished by passing a list of strings to `parse_args()`. This is useful for testing at the interactive prompt:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument(
...     'integers', metavar='int', type=int, choices=range(10),
...     nargs='+', help='an integer in the range 0..9')
>>> parser.add_argument(
...     '--sum', dest='accumulate', action='store_const',
...     default=max, help='sum the integers (default: find the max)')
>>> parser.parse_args(['1', '2', '3', '4'])
Namespace(accumulate=<built-in function max>, integers=[1, 2, 3, 4])
>>> parser.parse_args(['1', '2', '3', '4', '--sum'])
Namespace(accumulate=<built-in function sum>, integers=[1, 2, 3, 4])

```

## The Namespace object

*class* `argparse.Namespace`

Simple class used by default by `parse_args()` to create an object holding attributes and return it.

This class is deliberately simple, just an `object` subclass with a readable string representation. If you prefer to have dict-like view of the attributes, you can use the standard Python idiom, `vars()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> args = parser.parse_args(['--foo', 'BAR'])
>>> vars(args)
{'foo': 'BAR'}
```

It may also be useful to have an `ArgumentParser` assign attributes to an already existing object, rather than a new `Namespace` object. This can be achieved by specifying the `namespace=` keyword argument:

```
>>> class C:
...     pass
...
>>> c = C()
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args(args=['--foo', 'BAR'], namespace=c)
>>> c.foo
'BAR'
```

## Other utilities

### Sub-commands

```
ArgumentParser.add_subparsers([title] [, description] [, prog] [,
parser_class] [, action] [, option_strings] [, dest] [, required] [, help] [,
metavar])
```

Many programs split up their functionality into a number of sub-commands, for example, the `svn` program can invoke sub-commands like `svn checkout`, `svn update`, and `svn commit`. Splitting up functionality this way can be a particularly good idea when a program performs several different functions which require different kinds of command-line arguments. `ArgumentParser` supports the creation of such sub-commands with the `add_subparsers()` method. The `add_subparsers()` method is normally called with no arguments and returns a special action object. This object has

a single method, `add_parser()`, which takes a command name and any `ArgumentParser` constructor arguments, and returns an `ArgumentParser` object that can be modified as usual.

Description of parameters:

- `title` - title for the sub-parser group in help output; by default “subcommands” if description is provided, otherwise uses title for positional arguments
- `description` - description for the sub-parser group in help output, by default `None`
- `prog` - usage information that will be displayed with sub-command help, by default the name of the program and any positional arguments before the subparser argument
- `parser_class` - class which will be used to create sub-parser instances, by default the class of the current parser (e.g. `ArgumentParser`)
- `action` - the basic type of action to be taken when this argument is encountered at the command line
- `dest` - name of the attribute under which sub-command name will be stored; by default `None` and no value is stored
- `required` - Whether or not a subcommand must be provided, by default `False` (added in 3.7)
- `help` - help for sub-parser group in help output, by default `None`
- `metavar` - string presenting available sub-commands in help; by default it is `None` and presents sub-commands in form `{cmd1, cmd2, ..}`

Some example usage:

```
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', action='store_true')
>>> subparsers = parser.add_subparsers(help='sub-co
>>>
>>> # create the parser for the "a" command
```

```

>>> parser_a = subparsers.add_parser('a', help='a h
>>> parser_a.add_argument('bar', type=int, help='ba
>>>
>>> # create the parser for the "b" command
>>> parser_b = subparsers.add_parser('b', help='b h
>>> parser_b.add_argument('--baz', choices='XYZ', h
>>>
>>> # parse some argument lists
>>> parser.parse_args(['a', '12'])
Namespace(bar=12, foo=False)
>>> parser.parse_args(['--foo', 'b', '--baz', 'Z'])
Namespace(baz='Z', foo=True)

```

Note that the object returned by `parse_args()` will only contain attributes for the main parser and the subparser that was selected by the command line (and not any other subparsers). So in the example above, when the `a` command is specified, only the `foo` and `bar` attributes are present, and when the `b` command is specified, only the `foo` and `baz` attributes are present.

Similarly, when a help message is requested from a subparser, only the help for that particular parser will be printed. The help message will not include parent parser or sibling parser messages. (A help message for each subparser command, however, can be given by supplying the `help=` argument to `add_parser()` as above.)

```

>>> parser.parse_args(['--help'])
usage: PROG [-h] [--foo] {a,b} ...

```

positional arguments:

```

{a,b}    sub-command help
a        a help
b        b help

```

options:

```

-h, --help  show this help message and exit
--foo      foo help

```

```
>>> parser.parse_args(['a', '--help'])
usage: PROG a [-h] bar
```

```
positional arguments:
  bar      bar help
```

```
options:
  -h, --help  show this help message and exit
```

```
>>> parser.parse_args(['b', '--help'])
usage: PROG b [-h] [--baz {X,Y,Z}]
```

```
options:
  -h, --help          show this help message and exit
  --baz {X,Y,Z}      baz help
```

The `add_subparsers()` method also supports `title` and `description` keyword arguments. When either is present, the subparser's commands will appear in their own group in the help output. For example:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(title='subco
...                                     description=
...                                     help='additi
>>> subparsers.add_parser('foo')
>>> subparsers.add_parser('bar')
>>> parser.parse_args(['-h'])
usage:  [-h] {foo,bar} ...
```

```
options:
  -h, --help  show this help message and exit
```

```
subcommands:
  valid subcommands

  {foo,bar}  additional help
```

Furthermore, `add_parser` supports an additional `aliases` argument, which allows multiple strings to refer to the same subparser. This example, like `svn`, aliases `co` as a shorthand for `checkout`:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>> checkout = subparsers.add_parser('checkout', al
>>> checkout.add_argument('foo')
>>> parser.parse_args(['co', 'bar'])
Namespace(foo='bar')
```

One particularly effective way of handling sub-commands is to combine the use of the `add_subparsers()` method with calls to `set_defaults()` so that each subparser knows which Python function it should execute. For example:

```
>>> # sub-command functions
>>> def foo(args):
...     print(args.x * args.y)
...
>>> def bar(args):
...     print('((%s))' % args.z)
...
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(required=True)
>>>
>>> # create the parser for the "foo" command
>>> parser_foo = subparsers.add_parser('foo')
>>> parser_foo.add_argument('-x', type=int, default
>>> parser_foo.add_argument('y', type=float)
>>> parser_foo.set_defaults(func=foo)
>>>
>>> # create the parser for the "bar" command
>>> parser_bar = subparsers.add_parser('bar')
>>> parser_bar.add_argument('z')
>>> parser_bar.set_defaults(func=bar)
>>>
```

```
>>> # parse the args and call whatever function was
>>> args = parser.parse_args('foo 1 -x 2'.split())
>>> args.func(args)
2.0
>>>
>>> # parse the args and call whatever function was
>>> args = parser.parse_args('bar XYZYX'.split())
>>> args.func(args)
((XYZYX))
```

This way, you can let `parse_args()` do the job of calling the appropriate function after argument parsing is complete. Associating functions with actions like this is typically the easiest way to handle the different actions for each of your subparsers. However, if it is necessary to check the name of the subparser that was invoked, the `dest` keyword argument to the `add_subparsers()` call will work:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(dest='subpar
>>> subparser1 = subparsers.add_parser('1')
>>> subparser1.add_argument('-x')
>>> subparser2 = subparsers.add_parser('2')
>>> subparser2.add_argument('y')
>>> parser.parse_args(['2', 'frobble'])
Namespace(subparser_name='2', y='frobble')
```

*Changed in version 3.7: New required keyword argument.*

## FileType objects

```
class argparse.FileType(mode='r', bufsize=-1, encoding=None,
errors=None)
```

The `FileType` factory creates objects that can be passed to the type argument of `ArgumentParser.add_argument()`. Arguments that have `FileType` objects as their type will open command-line arguments as files with the requested modes, buffer sizes, encodings and error handling (see the `open()` function for more details):

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--raw', type=argparse.FileType)
>>> parser.add_argument('out', type=argparse.FileType)
>>> parser.parse_args(['--raw', 'raw.dat', 'file.txt'])
Namespace(out=<_io.TextIOWrapper name='file.txt' mode='r' encoding='utf-8'>)
```

FileType objects understand the pseudo-argument '-' and automatically convert this into `sys.stdin` for readable `FileType` objects and `sys.stdout` for writable `FileType` objects:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', type=argparse.FileType)
>>> parser.parse_args(['-'])
Namespace(infile=<_io.TextIOWrapper name='<stdin>' mode='r' encoding='utf-8'>)
```

*New in version 3.4:* The *encodings* and *errors* keyword arguments.

## Argument groups

`ArgumentParser.add_argument_group(title=None, description=None)`

By default, `ArgumentParser` groups command-line arguments into “positional arguments” and “options” when displaying help messages. When there is a better conceptual grouping of arguments than this default one, appropriate groups can be created using the `add_argument_group()` method:

```
>>> parser = argparse.ArgumentParser(prog='PROG', description='A sample program')
>>> group = parser.add_argument_group('group')
>>> group.add_argument('--foo', help='foo help')
>>> group.add_argument('bar', help='bar help')
>>> parser.print_help()
usage: PROG [--foo FOO] bar
```

```
group:
  bar      bar help
```

```
--foo FOO  foo help
```

The `add_argument_group()` method returns an argument group object which has an `add_argument()` method just like a regular `ArgumentParser`. When an argument is added to the group, the parser treats it just like a normal argument, but displays the argument in a separate group for help messages. The `add_argument_group()` method accepts *title* and *description* arguments which can be used to customize this display:

```
>>> parser = argparse.ArgumentParser(prog='PROG', a
>>> group1 = parser.add_argument_group('group1', 'g
>>> group1.add_argument('foo', help='foo help')
>>> group2 = parser.add_argument_group('group2', 'g
>>> group2.add_argument('--bar', help='bar help')
>>> parser.print_help()
usage: PROG [--bar BAR] foo
```

```
group1:
  group1 description

  foo      foo help

group2:
  group2 description

  --bar BAR  bar help
```

Note that any arguments not in your user-defined groups will end up back in the usual “positional arguments” and “optional arguments” sections.

*Changed in version 3.11:* Calling `add_argument_group()` on an argument group is deprecated. This feature was never supported and does not always work correctly. The function exists on the API by accident through inheritance and will be removed in the future.

## Mutual exclusion

## ArgumentParser.add\_mutually\_exclusive\_group(required=False)

Create a mutually exclusive group. `argparse` will make sure that only one of the arguments in the mutually exclusive group was present on the command line:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group()
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args(['--foo'])
Namespace(bar=True, foo=True)
>>> parser.parse_args(['--bar'])
Namespace(bar=False, foo=False)
>>> parser.parse_args(['--foo', '--bar'])
usage: PROG [-h] [--foo | --bar]
PROG: error: argument --bar: not allowed with argument
```

The `add_mutually_exclusive_group()` method also accepts a *required* argument, to indicate that at least one of the mutually exclusive arguments is required:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group(required=True)
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args([])
usage: PROG [-h] (--foo | --bar)
PROG: error: one of the arguments --foo --bar is required
```

Note that currently mutually exclusive argument groups do not support the *title* and *description* arguments of `add_argument_group()`.

*Changed in version 3.11:* Calling `add_argument_group()` or `add_mutually_exclusive_group()` on a mutually exclusive group is deprecated. These features were never supported and do not always work correctly. The functions exist on the API by accident through inheritance and will be removed in the future.

## Parser defaults

### `ArgumentParser.set_defaults(**kwargs)`

Most of the time, the attributes of the object returned by `parse_args()` will be fully determined by inspecting the command-line arguments and the argument actions. `set_defaults()` allows some additional attributes that are determined without any inspection of the command line to be added:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.set_defaults(bar=42, baz='badger')
>>> parser.parse_args(['736'])
Namespace(bar=42, baz='badger', foo=736)
```

Note that parser-level defaults always override argument-level defaults:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='bar')
>>> parser.set_defaults(foo='spam')
>>> parser.parse_args([])
Namespace(foo='spam')
```

Parser-level defaults can be particularly useful when working with multiple parsers. See the `add_subparsers()` method for an example of this type.

### `ArgumentParser.get_default(dest)`

Get the default value for a namespace attribute, as set by either `add_argument()` or by `set_defaults()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='badger')
>>> parser.get_default('foo')
'badger'
```

## Printing help

In most typical applications, `parse_args()` will take care of formatting and printing any usage or error messages. However, several formatting methods are available:

`ArgumentParser.print_usage(file=None)`

Print a brief description of how the `ArgumentParser` should be invoked on the command line. If `file` is `None`, `sys.stdout` is assumed.

`ArgumentParser.print_help(file=None)`

Print a help message, including the program usage and information about the arguments registered with the `ArgumentParser`. If `file` is `None`, `sys.stdout` is assumed.

There are also variants of these methods that simply return a string instead of printing it:

`ArgumentParser.format_usage()`

Return a string containing a brief description of how the `ArgumentParser` should be invoked on the command line.

`ArgumentParser.format_help()`

Return a string containing a help message, including the program usage and information about the arguments registered with the `ArgumentParser`.

## Partial parsing

`ArgumentParser.parse_known_args(args=None, namespace=None)`

Sometimes a script may only parse a few of the command-line arguments, passing the remaining arguments on to another script or program. In these cases, the `parse_known_args()` method can be useful. It works much like `parse_args()` except that it does not produce an error when extra arguments are present. Instead, it returns a two item tuple containing the populated namespace and the list of remaining argument strings.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('bar')
>>> parser.parse_known_args(['--foo', '--badger', 'BAR',
(Namespace(bar='BAR', foo=True), ['--badger', 'spam']))
```

## Warning

[Prefix matching](#) rules apply to [parse\\_known\\_args\(\)](#). The parser may consume an option even if it's just a prefix of one of its known options, instead of leaving it in the remaining arguments list.

## Customizing file parsing

`ArgumentParser.convert_arg_line_to_args(arg_line)`

Arguments that are read from a file (see the *fromfile\_prefix\_chars* keyword argument to the [ArgumentParser](#) constructor) are read one argument per line. [convert\\_arg\\_line\\_to\\_args\(\)](#) can be overridden for fancier reading.

This method takes a single argument *arg\_line* which is a string read from the argument file. It returns a list of arguments parsed from this string. The method is called once per line read from the argument file, in order.

A useful override of this method is one that treats each space-separated word as an argument. The following example demonstrates how to do this:

```
class MyArgumentParser(argparse.ArgumentParser):
    def convert_arg_line_to_args(self, arg_line):
        return arg_line.split()
```

## Exiting methods

`ArgumentParser.exit(status=0, message=None)`

This method terminates the program, exiting with the specified *status* and, if given, it prints a *message* before that. The user can override this method to handle these steps differently:

```
class ErrorCatchingArgumentParser(argparse.ArgumentParser):
    def exit(self, status=0, message=None):
        if status:
            raise Exception(f'Exiting because of an error: {message}')
        exit(status)
```

`ArgumentParser.error(message)`

This method prints a usage message including the *message* to the standard error and terminates the program with a status code of 2.

## Intermixed parsing

`ArgumentParser.parse_intermixed_args(args = None, namespace = None)`

`ArgumentParser.parse_known_intermixed_args(args = None, namespace = None)`

A number of Unix commands allow the user to intermix optional arguments with positional arguments. The `parse_intermixed_args()` and `parse_known_intermixed_args()` methods support this parsing style.

These parsers do not support all the `argparse` features, and will raise exceptions if unsupported features are used. In particular, subparsers, and mutually exclusive groups that include both optionals and positionals are not supported.

The following example shows the difference between `parse_known_args()` and `parse_intermixed_args()`: the former returns `['2', '3']` as unparsed arguments, while the

latter collects all the positionals into `rest`.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('cmd')
>>> parser.add_argument('rest', nargs='*', type=int)
>>> parser.parse_known_args('doit 1 --foo bar 2 3'.split()
(Namespace(cmd='doit', foo='bar', rest=[1]), ['2', '3']))
>>> parser.parse_intermixed_args('doit 1 --foo bar 2 3'.split())
Namespace(cmd='doit', foo='bar', rest=[1, 2, 3])
```

`parse_known_intermixed_args()` returns a two item tuple containing the populated namespace and the list of remaining argument strings. `parse_intermixed_args()` raises an error if there are any remaining unparsed argument strings.

*New in version 3.7.*

## Upgrading optparse code

Originally, the `argparse` module had attempted to maintain compatibility with `optparse`. However, `optparse` was difficult to extend transparently, particularly with the changes required to support the new `nargs=` specifiers and better usage messages. When most everything in `optparse` had either been copy-pasted over or monkey-patched, it no longer seemed practical to try to maintain the backwards compatibility.

The `argparse` module improves on the standard library `optparse` module in a number of ways including:

- Handling positional arguments.
- Supporting sub-commands.
- Allowing alternative option prefixes like `+` and `/`.
- Handling zero-or-more and one-or-more style arguments.
- Producing more informative usage messages.
- Providing a much simpler interface for custom `type` and `action`.

A partial upgrade path from `optparse` to `argparse`:

- Replace all `optparse.OptionParser.add_option()` calls with `ArgumentParser.add_argument()` calls.
- Replace `(options, args) = parser.parse_args()` with `args = parser.parse_args()` and add additional `ArgumentParser.add_argument()` calls for the positional arguments. Keep in mind that what was previously called `options`, now in the `argparse` context is called `args`.
- Replace `optparse.OptionParser.disable_interspersed_args()` by using `parse_intermixed_args()` instead of `parse_args()`.
- Replace callback actions and the `callback_*` keyword arguments with `type` or `action` arguments.
- Replace string names for `type` keyword arguments with the corresponding type objects (e.g. `int`, `float`, `complex`, etc).
- Replace `optparse.Values` with `Namespace` and `optparse.OptionError` and `optparse.OptionValueError` with `ArgumentError`.
- Replace strings with implicit arguments such as `%default` or `%prog` with the standard Python syntax to use dictionaries to format strings, that is, `%(default)s` and `%(prog)s`.
- Replace the `OptionParser` constructor `version` argument with a call to `parser.add_argument('--version', action='version', version='<the version>')`.

## Exceptions

*exception* `argparse.ArgumentError`

An error from creating or using an argument (optional or positional).

The string value of this exception is the message, augmented with information about the argument that caused it.

*exception* `argparse.ArgumentTypeError`

Raised when something goes wrong converting a command line string to a type.

# getopt — C-style parser for command line options

**Source code:** [Lib/getopt.py](https://github.com/python/cpython/tree/3.11/Lib/getopt.py) [https://github.com/python/cpython/tree/3.11/Lib/getopt.py]

## Note

The **getopt** module is a parser for command line options whose API is designed to be familiar to users of the C **getopt()** function. Users who are unfamiliar with the C **getopt()** function or who would like to write less code and get better help and error messages should consider using the **argparse** module instead.

---

This module helps scripts to parse the command line arguments in `sys.argv`. It supports the same conventions as the Unix **getopt()** function (including the special meanings of arguments of the form `'-'` and `'--'`). Long options similar to those supported by GNU software may be used as well via an optional third argument.

This module provides two functions and an exception:

`getopt.getopt(args, shortopts, longopts = [])`

Parses command line options and parameter list. *args* is the argument list to be parsed, without the leading reference to the running program. Typically, this means `sys.argv[1:]`. *shortopts* is the string of option letters that the script wants to recognize, with options that require an argument followed by a colon (`' : '`; i.e., the same format that Unix **getopt()** uses).

## Note

Unlike GNU `getopt()`, after a non-option argument, all further arguments are considered also non-options. This is similar to the way non-GNU Unix systems work.

*longopts*, if specified, must be a list of strings with the names of the long options which should be supported. The leading '--' characters should not be included in the option name. Long options which require an argument should be followed by an equal sign ('='). Optional arguments are not supported. To accept only long options, *shortopts* should be an empty string. Long options on the command line can be recognized so long as they provide a prefix of the option name that matches exactly one of the accepted options. For example, if *longopts* is ['foo', 'frob'], the option --foo will match as --foo, but --f will not match uniquely, so `GetoptError` will be raised.

The return value consists of two elements: the first is a list of (option, value) pairs; the second is the list of program arguments left after the option list was stripped (this is a trailing slice of *args*). Each option-and-value pair returned has the option as its first element, prefixed with a hyphen for short options (e.g., '-x') or two hyphens for long options (e.g., '--long-option'), and the option argument as its second element, or an empty string if the option has no argument. The options occur in the list in the same order in which they were found, thus allowing multiple occurrences. Long and short options may be mixed.

`getopt.gnu_getopt(args, shortopts, longopts = [])`

This function works like `getopt()`, except that GNU style scanning mode is used by default. This means that option and non-option arguments may be intermixed. The `getopt()` function stops processing options as soon as a non-option argument is encountered.

If the first character of the option string is '+', or if the environment variable `POSIXLY_CORRECT` is set, then option processing stops as soon as a non-option argument is

encountered.

*exception* getopt.GetoptError

This is raised when an unrecognized option is found in the argument list or when an option requiring an argument is given none. The argument to the exception is a string indicating the cause of the error. For long options, an argument given to an option which does not require one will also cause this exception to be raised. The attributes **msg** and **opt** give the error message and related option; if there is no specific option to which the exception relates, **opt** is an empty string.

*exception* getopt.error

Alias for **GetoptError**; for backward compatibility.

An example using only Unix style options:

```
>>> import getopt
>>> args = '-a -b -cfoo -d bar a1 a2'.split()
>>> args
['-a', '-b', '-cfoo', '-d', 'bar', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'abc:d:')
>>> optlist
[('-a', ''), ('-b', ''), ('-c', 'foo'), ('-d', 'bar')]
>>> args
['a1', 'a2']
```

Using long option names is equally easy:

```
>>> s = '--condition=foo --testing --output-file abc.def'
>>> args = s.split()
>>> args
['--condition=foo', '--testing', '--output-file', 'abc.def']
>>> optlist, args = getopt.getopt(args, 'x', [
...     'condition=', 'output-file=', 'testing'])
>>> optlist
[('--condition', 'foo'), ('--testing', ''), ('--output-f', 'abc.def')]
>>> args
```

```
['a1', 'a2']
```

In a script, typical usage is something like this:

```
import getopt, sys
```

```
def main():
    try:
        opts, args = getopt.getopt(sys.argv[1:], "ho:v",
    except getopt.GetoptError as err:
        # print help information and exit:
        print(err) # will print something like "option
        usage()
        sys.exit(2)
    output = None
    verbose = False
    for o, a in opts:
        if o == "-v":
            verbose = True
        elif o in ("-h", "--help"):
            usage()
            sys.exit()
        elif o in ("-o", "--output"):
            output = a
        else:
            assert False, "unhandled option"
    # ...

if __name__ == "__main__":
    main()
```

Note that an equivalent command line interface could be produced with less code and more informative help and error messages by using the [argparse](#) module:

```
import argparse
```

```
if __name__ == '__main__':
    parser = argparse.ArgumentParser()
```

```
parser.add_argument('-o', '--output')
parser.add_argument('-v', dest='verbose', action='store_true')
args = parser.parse_args()
# ... do something with args.output ...
# ... do something with args.verbose ..
```

# logging — Logging facility for Python

**Source code:** [Lib/logging/\\_init\\_.py](https://github.com/python/cpython/tree/3.11/Lib/logging/_init_.py) [https://github.com/python/cpython/tree/3.11/Lib/logging/\_init\_.py]

## Important

This page contains the API reference information. For tutorial information and discussion of more advanced topics, see

- [Basic Tutorial](#)
  - [Advanced Tutorial](#)
  - [Logging Cookbook](#)
- 

This module defines functions and classes which implement a flexible event logging system for applications and libraries.

The key benefit of having the logging API provided by a standard library module is that all Python modules can participate in logging, so your application log can include your own messages integrated with messages from third-party modules.

The simplest example:

```
>>> import logging
>>> logging.warning('Watch out!')
WARNING:root:Watch out!
```

The module provides a lot of functionality and flexibility. If you are unfamiliar with logging, the best way to get to grips with it is to view the tutorials (**see the links above and on the right**).

The basic classes defined by the module, together with their functions, are listed below.

- Loggers expose the interface that application code directly uses.
- Handlers send the log records (created by loggers) to the appropriate destination.
- Filters provide a finer grained facility for determining which log records to output.
- Formatters specify the layout of log records in the final output.

## Logger Objects

Loggers have the following attributes and methods. Note that Loggers should *NEVER* be instantiated directly, but always through the module-level function `logging.getLogger(name)`. Multiple calls to `getLogger()` with the same name will always return a reference to the same Logger object.

The `name` is potentially a period-separated hierarchical value, like `foo.bar.baz` (though it could also be just plain `foo`, for example). Loggers that are further down in the hierarchical list are children of loggers higher up in the list. For example, given a logger with a name of `foo`, loggers with names of `foo.bar`, `foo.bar.baz`, and `foo.bam` are all descendants of `foo`. The logger name hierarchy is analogous to the Python package hierarchy, and identical to it if you organise your loggers on a per-module basis using the recommended construction `logging.getLogger(__name__)`. That's because in a module, `__name__` is the module's name in the Python package namespace.

`class logging.Logger`

`propagate`

If this attribute evaluates to true, events logged to this logger will be passed to the handlers of higher level (ancestor) loggers, in addition to any handlers attached to this logger. Messages are passed directly to the ancestor loggers' handlers - neither the level nor filters of the ancestor loggers in question are considered.

If this evaluates to false, logging messages are not

passed to the handlers of ancestor loggers.

Spelling it out with an example: If the `propagate` attribute of the logger named `A.B.C` evaluates to `true`, any event logged to `A.B.C` via a method call such as `logging.getLogger('A.B.C').error(...)` will [subject to passing that logger's level and filter settings] be passed in turn to any handlers attached to loggers named `A.B`, `A` and the root logger, after first being passed to any handlers attached to `A.B.C`. If any logger in the chain `A.B.C`, `A.B`, `A` has its `propagate` attribute set to `false`, then that is the last logger whose handlers are offered the event to handle, and propagation stops at that point.

The constructor sets this attribute to `True`.

### Note

If you attach a handler to a logger *and* one or more of its ancestors, it may emit the same record multiple times. In general, you should not need to attach a handler to more than one logger - if you just attach it to the appropriate logger which is highest in the logger hierarchy, then it will see all events logged by all descendant loggers, provided that their `propagate` setting is left set to `True`. A common scenario is to attach handlers only to the root logger, and to let propagation take care of the rest.

### `setLevel(level)`

Sets the threshold for this logger to *level*. Logging messages which are less severe than *level* will be ignored; logging messages which have severity *level* or higher will be emitted by whichever handler or handlers service this logger, unless a handler's level has been set to a higher severity level than *level*.

When a logger is created, the level is set to **NOTSET**

(which causes all messages to be processed when the logger is the root logger, or delegation to the parent when the logger is a non-root logger). Note that the root logger is created with level **WARNING**.

The term ‘delegation to the parent’ means that if a logger has a level of NOTSET, its chain of ancestor loggers is traversed until either an ancestor with a level other than NOTSET is found, or the root is reached.

If an ancestor is found with a level other than NOTSET, then that ancestor’s level is treated as the effective level of the logger where the ancestor search began, and is used to determine how a logging event is handled.

If the root is reached, and it has a level of NOTSET, then all messages will be processed. Otherwise, the root’s level will be used as the effective level.

See [Logging Levels](#) for a list of levels.

*Changed in version 3.2:* The *level* parameter now accepts a string representation of the level such as ‘INFO’ as an alternative to the integer constants such as **INFO**. Note, however, that levels are internally stored as integers, and methods such as e.g. [getEffectiveLevel\(\)](#) and [isEnabledFor\(\)](#) will return/expect to be passed integers.

### `isEnabledFor(level)`

Indicates if a message of severity *level* would be processed by this logger. This method checks first the module-level level set by `logging.disable(level)` and then the logger’s effective level as determined by [getEffectiveLevel\(\)](#).

### `getEffectiveLevel()`

Indicates the effective level for this logger. If a value other than **NOTSET** has been set using [setLevel\(\)](#), it is returned. Otherwise, the hierarchy is traversed

towards the root until a value other than **NOTSET** is found, and that value is returned. The value returned is an integer, typically one of **logging.DEBUG**, **logging.INFO** etc.

### `getChild(suffix)`

Returns a logger which is a descendant to this logger, as determined by the suffix. Thus, `logging.getLogger('abc').getChild('def.ghi')` would return the same logger as would be returned by `logging.getLogger('abc.def.ghi')`. This is a convenience method, useful when the parent logger is named using e.g. `__name__` rather than a literal string.

*New in version 3.2.*

### `debug(msg, *args, **kwargs)`

Logs a message with level **DEBUG** on this logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.) No % formatting operation is performed on *msg* when no *args* are supplied.

There are four keyword arguments in *kwargs* which are inspected: *exc\_info*, *stack\_info*, *stacklevel* and *extra*.

If *exc\_info* does not evaluate as false, it causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) or an exception instance is provided, it is used; otherwise, `sys.exc_info()` is called to get the exception information.

The second optional keyword argument is *stack\_info*, which defaults to `False`. If true, stack information is added to the logging message, including the actual

logging call. Note that this is not the same stack information as that displayed through specifying *exc\_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify *stack\_info* independently of *exc\_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback (most recent call last):` which is used when displaying exception frames.

The third optional keyword argument is *stacklevel*, which defaults to 1. If greater than 1, the corresponding number of stack frames are skipped when computing the line number and function name set in the `LogRecord` created for the logging event. This can be used in logging helpers so that the function name, filename and line number recorded are not the information for the helper function/method, but rather its caller. The name of this parameter mirrors the equivalent one in the `warnings` module.

The fourth keyword argument is *extra* which can be used to pass a dictionary which is used to populate the `_dict_` of the `LogRecord` created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)s %(clientip)-15s %(user)-8s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fblogg
```

```
logger = logging.getLogger('tcpserver')
logger.warning('Protocol problem: %s', 'connect
```

would print something like

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs Pr
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the section on [LogRecord attributes](#) for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the [Formatter](#) has been set up with a format string which expects ‘clientip’ and ‘user’ in the attribute dictionary of the [LogRecord](#). If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized [Formatters](#) would be used with particular [Handlers](#).

If no handler is attached to this logger (or any of its ancestors, taking into account the relevant [Logger.propagate](#) attributes), the message will be sent to the handler set on [lastResort](#).

*Changed in version 3.2:* The *stack\_info* parameter was added.

*Changed in version 3.5:* The *exc\_info* parameter can now

accept exception instances.

*Changed in version 3.8:* The *stacklevel* parameter was added.

`info(msg, *args, **kwargs)`

Logs a message with level **INFO** on this logger. The arguments are interpreted as for `debug()`.

`warning(msg, *args, **kwargs)`

Logs a message with level **WARNING** on this logger. The arguments are interpreted as for `debug()`.

### Note

There is an obsolete method `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

`error(msg, *args, **kwargs)`

Logs a message with level **ERROR** on this logger. The arguments are interpreted as for `debug()`.

`critical(msg, *args, **kwargs)`

Logs a message with level **CRITICAL** on this logger. The arguments are interpreted as for `debug()`.

`log(level, msg, *args, **kwargs)`

Logs a message with integer level *level* on this logger. The other arguments are interpreted as for `debug()`.

`exception(msg, *args, **kwargs)`

Logs a message with level **ERROR** on this logger. The arguments are interpreted as for `debug()`. Exception info is added to the logging message. This method

should only be called from an exception handler.

`addFilter(filter)`

Adds the specified filter *filter* to this logger.

`removeFilter(filter)`

Removes the specified filter *filter* from this logger.

`filter(record)`

Apply this logger's filters to the record and return `True` if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be processed (passed to handlers). If one returns a false value, no further processing of the record occurs.

`addHandler(hdlr)`

Adds the specified handler *hdlr* to this logger.

`removeHandler(hdlr)`

Removes the specified handler *hdlr* from this logger.

`findCaller(stack_info = False, stacklevel = 1)`

Finds the caller's source filename and line number. Returns the filename, line number, function name and stack information as a 4-element tuple. The stack information is returned as `None` unless *stack\_info* is `True`.

The *stacklevel* parameter is passed from code calling the `debug()` and other APIs. If greater than 1, the excess is used to skip stack frames before determining the values to be returned. This will generally be useful when calling logging APIs from helper/wrapper code, so that the information in the event log refers not to the helper/wrapper code, but to the code that calls it.

`handle(record)`

Handles a record by passing it to all handlers associated with this logger and its ancestors (until a false value of *propagate* is found). This method is used for unpickled records received from a socket, as well as those created locally. Logger-level filtering is applied using `filter()`.

`makeRecord(name, level, fn, lno, msg, args, exc_info, func=None, extra=None, info=None)`

This is a factory method which can be overridden in subclasses to create specialized `LogRecord` instances.

`hasHandlers()`

Checks to see if this logger has any handlers configured. This is done by looking for handlers in this logger and its parents in the logger hierarchy. Returns `True` if a handler was found, else `False`. The method stops searching up the hierarchy whenever a logger with the ‘propagate’ attribute set to false is found - that will be the last logger which is checked for the existence of handlers.

*New in version 3.2.*

*Changed in version 3.7:* Loggers can now be pickled and unpickled.

## Logging Levels

The numeric values of logging levels are given in the following table. These are primarily of interest if you want to define your own levels, and need them to have specific values relative to the predefined levels. If you define a level with the same numeric value, it overwrites the predefined value; the predefined name is lost.

| Numeric value | Level name |
|---------------|------------|
|---------------|------------|

|    |          |
|----|----------|
| 50 | CRITICAL |
|----|----------|

~~40~~ERROR

~~30~~WARNING

~~20~~INFO

~~10~~DEBUG

NOTSET

## Handler Objects

Handlers have the following attributes and methods. Note that **Handler** is never instantiated directly; this class acts as a base for more useful subclasses. However, the `__init__()` method in subclasses needs to call `Handler.__init__()`.

`class logging.Handler`

`__init__(level=NOTSET)`

Initializes the **Handler** instance by setting its level, setting the list of filters to the empty list and creating a lock (using `createLock()`) for serializing access to an I/O mechanism.

`createLock()`

Initializes a thread lock which can be used to serialize access to underlying I/O functionality which may not be threadsafe.

`acquire()`

Acquires the thread lock created with `createLock()`.

`release()`

Releases the thread lock acquired with `acquire()`.

`setLevel(level)`

Sets the threshold for this handler to *level*. Logging messages which are less severe than *level* will be ignored. When a handler is created, the level is set to **NOTSET** (which causes all messages to be processed).

See [Logging Levels](#) for a list of levels.

*Changed in version 3.2:* The *level* parameter now accepts a string representation of the level such as 'INFO' as an alternative to the integer constants such as **INFO**.

`setFormatter(fmt)`

Sets the **Formatter** for this handler to *fmt*.

`addFilter(filter)`

Adds the specified filter *filter* to this handler.

`removeFilter(filter)`

Removes the specified filter *filter* from this handler.

`filter(record)`

Apply this handler's filters to the record and return `True` if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be emitted. If one returns a false value, the handler will not emit the record.

`flush()`

Ensure all logging output has been flushed. This version does nothing and is intended to be implemented by subclasses.

`close()`

Tidy up any resources used by the handler. This version does no output but removes the handler from an internal list of handlers which is closed when **`shutdown()`** is called. Subclasses should ensure that this gets called from overridden **`close()`** methods.

`handle(record)`

Conditionally emits the specified logging record, depending on filters which may have been added to the handler. Wraps the actual emission of the record with acquisition/release of the I/O thread lock.

### `handleError(record)`

This method should be called from handlers when an exception is encountered during an `emit()` call. If the module-level attribute `raiseExceptions` is `False`, exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors. You could, however, replace this with a custom handler if you wish. The specified record is the one which was being processed when the exception occurred. (The default value of `raiseExceptions` is `True`, as that is more useful during development).

### `format(record)`

Do formatting for a record - if a formatter is set, use it. Otherwise, use the default formatter for the module.

### `emit(record)`

Do whatever it takes to actually log the specified logging record. This version is intended to be implemented by subclasses and so raises a **`NotImplementedError`**.

### **Warning**

This method is called after a handler-level lock is acquired, which is released after this method returns. When you override this method, note that you should be careful when calling anything that invokes other parts of the logging API which might do locking, because that might result in a deadlock. Specifically:

- Logging configuration APIs acquire the module-level lock, and then individual handler-level locks as those handlers are configured.
- Many logging APIs lock the module-level lock. If such an API is called from this method, it could cause a deadlock if a configuration call is made on another thread, because that thread will try to acquire the module-level lock *before* the handler-level lock, whereas this thread tries to acquire the module-level lock *after* the handler-level lock (because in this method, the handler-level lock has already been acquired).

For a list of handlers included as standard, see [logging.handlers](#).

## Formatter Objects

**Formatter** objects have the following attributes and methods. They are responsible for converting a **LogRecord** to (usually) a string which can be interpreted by either a human or an external system. The base **Formatter** allows a formatting string to be specified. If none is supplied, the default value of `'%(message)s'` is used, which just includes the message in the logging call. To have additional items of information in the formatted output (such as a timestamp), keep reading.

A Formatter can be initialized with a format string which makes use of knowledge of the **LogRecord** attributes - such as the default value mentioned above making use of the fact that the user's message and arguments are pre-formatted into a **LogRecord**'s *message* attribute. This format string contains standard Python %-style mapping keys. See section [printf-style String Formatting](#) for more information on string formatting.

The useful mapping keys in a **LogRecord** are given in the section

on [LogRecord](#) attributes.

```
class logging.Formatter(fmt=None, datefmt=None, style='%',  
validate=True, *, defaults=None)
```

Returns a new instance of the [Formatter](#) class. The instance is initialized with a format string for the message as a whole, as well as a format string for the date/time portion of a message. If no *fmt* is specified, '%(message)s' is used. If no *datefmt* is specified, a format is used which is described in the [formatTime\(\)](#) documentation.

The *style* parameter can be one of '%', '{' or '\$' and determines how the format string will be merged with its data: using one of %-formatting, [str.format\(\)](#) or [string.Template](#). This only applies to the format string *fmt* (e.g. '%(message)s' or {message}), not to the actual log messages passed to `Logger.debug` etc; see [Using particular formatting styles throughout your application](#) for more information on using {- and \$-formatting for log messages.

The *defaults* parameter can be a dictionary with default values to use in custom fields. For example:

```
logging.Formatter('%(ip)s %(message)s',  
defaults={'ip': None})
```

*Changed in version 3.2:* The *style* parameter was added.

*Changed in version 3.8:* The *validate* parameter was added.

Incorrect or mismatched style and *fmt* will raise a `ValueError`. For example:

```
logging.Formatter('%(asctime)s - %(message)s',  
style='{').
```

*Changed in version 3.10:* The *defaults* parameter was added.

```
format(record)
```

The record's attribute dictionary is used as the operand to a string formatting operation. Returns the resulting string. Before formatting the dictionary, a couple of

preparatory steps are carried out. The *message* attribute of the record is computed using *msg % args*. If the formatting string contains *'(asctime)'*, *formatTime()* is called to format the event time. If there is exception information, it is formatted using *formatException()* and appended to the message. Note that the formatted exception information is cached in attribute *exc\_text*. This is useful because the exception information can be pickled and sent across the wire, but you should be careful if you have more than one *Formatter* subclass which customizes the formatting of exception information. In this case, you will have to clear the cached value (by setting the *exc\_text* attribute to *None*) after a formatter has done its formatting, so that the next formatter to handle the event doesn't use the cached value, but recalculates it afresh.

If stack information is available, it's appended after the exception information, using *formatStack()* to transform it if necessary.

*formatTime(record, datefmt=None)*

This method should be called from *format()* by a formatter which wants to make use of a formatted time. This method can be overridden in formatters to provide for any specific requirement, but the basic behavior is as follows: if *datefmt* (a string) is specified, it is used with *time.strftime()* to format the creation time of the record. Otherwise, the format *'%Y-%m-%d %H:%M:%S,uuu'* is used, where the *uuu* part is a millisecond value and the other letters are as per the *time.strftime()* documentation. An example time in this format is *2003-01-23 00:29:50,411*. The resulting string is returned.

This function uses a user-configurable function to convert the creation time to a tuple. By default, *time.localtime()* is used; to change this for a particular formatter instance, set the *converter*

attribute to a function with the same signature as `time.localtime()` or `time.gmtime()`. To change it for all formatters, for example if you want all logging times to be shown in GMT, set the `converter` attribute in the `Formatter` class.

*Changed in version 3.3:* Previously, the default format was hard-coded as in this example: `2010-09-06 22:38:15,292` where the part before the comma is handled by a `strftime` format string (`'%Y-%m-%d %H:%M:%S'`), and the part after the comma is a millisecond value. Because `strftime` does not have a format placeholder for milliseconds, the millisecond value is appended using another format string, `'%s, %03d'` — and both of these format strings have been hardcoded into this method. With the change, these strings are defined as class-level attributes which can be overridden at the instance level when desired. The names of the attributes are `default_time_format` (for the `strftime` format string) and `default_msec_format` (for appending the millisecond value).

*Changed in version 3.9:* The `default_msec_format` can be `None`.

`formatException(exc_info)`

Formats the specified exception information (a standard exception tuple as returned by `sys.exc_info()`) as a string. This default implementation just uses `traceback.print_exception()`. The resulting string is returned.

`formatStack(stack_info)`

Formats the specified stack information (a string as returned by `traceback.print_stack()`, but with the last newline removed) as a string. This default implementation just returns the input value.

`class logging.BufferingFormatter(linefmt = None)`

A base formatter class suitable for subclassing when you want to format a number of records. You can pass a `Formatter` instance which you want to use to format each line (that corresponds to a single record). If not specified, the default formatter (which just outputs the event message) is used as the line formatter.

`formatHeader(records)`

Return a header for a list of *records*. The base implementation just returns the empty string. You will need to override this method if you want specific behaviour, e.g. to show the count of records, a title or a separator line.

`formatFooter(records)`

Return a footer for a list of *records*. The base implementation just returns the empty string. You will need to override this method if you want specific behaviour, e.g. to show the count of records or a separator line.

`format(records)`

Return formatted text for a list of *records*. The base implementation just returns the empty string if there are no records; otherwise, it returns the concatenation of the header, each record formatted with the line formatter, and the footer.

## Filter Objects

`Filters` can be used by `Handlers` and `Loggers` for more sophisticated filtering than is provided by levels. The base filter class only allows events which are below a certain point in the logger hierarchy. For example, a filter initialized with 'A.B' will allow events logged by loggers 'A.B', 'A.B.C', 'A.B.C.D', 'A.B.D' etc. but not 'A.BB', 'B.A.B' etc. If initialized with the empty string, all

events are passed.

`class logging.Filter(name = "")`

Returns an instance of the `Filter` class. If *name* is specified, it names a logger which, together with its children, will have its events allowed through the filter. If *name* is the empty string, allows every event.

`filter(record)`

Is the specified record to be logged? Returns zero for no, nonzero for yes. If deemed appropriate, the record may be modified in-place by this method.

Note that filters attached to handlers are consulted before an event is emitted by the handler, whereas filters attached to loggers are consulted whenever an event is logged (using `debug()`, `info()`, etc.), before sending an event to handlers. This means that events which have been generated by descendant loggers will not be filtered by a logger's filter setting, unless the filter has also been applied to those descendant loggers.

You don't actually need to subclass `Filter`: you can pass any instance which has a `filter` method with the same semantics.

*Changed in version 3.2:* You don't need to create specialized `Filter` classes, or use other classes with a `filter` method: you can use a function (or other callable) as a filter. The filtering logic will check to see if the filter object has a `filter` attribute: if it does, it's assumed to be a `Filter` and its `filter()` method is called. Otherwise, it's assumed to be a callable and called with the record as the single parameter. The returned value should conform to that returned by `filter()`.

Although filters are used primarily to filter records based on more sophisticated criteria than levels, they get to see every record which is processed by the handler or logger they're attached to: this can be useful if you want to do things like counting how many records were processed by a particular logger or handler, or adding, changing or removing attributes in the `LogRecord` being processed. Obviously changing the `LogRecord` needs to be done

with some care, but it does allow the injection of contextual information into logs (see [Using Filters to impart contextual information](#)).

## LogRecord Objects

**LogRecord** instances are created automatically by the **Logger** every time something is logged, and can be created manually via **makeLogRecord()** (for example, from a pickled event received over the wire).

```
class logging.LogRecord(name, level, pathname, lineno, msg, args,  
exc_info, func = None, sinfo = None)
```

Contains all the information pertinent to the event being logged.

The primary information is passed in *msg* and *args*, which are combined using `msg % args` to create the **message** attribute of the record.

### Parameters

- **name** (*str*) – The name of the logger used to log the event represented by this **LogRecord**. Note that the logger name in the **LogRecord** will always have this value, even though it may be emitted by a handler attached to a different (ancestor) logger.
- **level** (*int*) – The [numeric level](#) of the logging event (such as 10 for `DEBUG`, 20 for `INFO`, etc). Note that this is converted to *two* attributes of the **LogRecord**: **levelno** for the numeric value and **levelname** for the corresponding level name.
- **pathname** (*str*) – The full string path of the source file where the logging call was made.
- **lineno** (*int*) – The line number in the

source file where the logging call was made.

- **msg** (*Any*) – The event description message, which can be a %-format string with placeholders for variable data, or an arbitrary object (see [Using arbitrary objects as messages](#)).
- **args** (*tuple* | *dict[str, Any]*) – Variable data to merge into the *msg* argument to obtain the event description.
- **exc\_info** (*tuple*[*type*[*BaseException*], *BaseException*, *types.TracebackType*] | *None*) – An exception tuple with the current exception information, as returned by `sys.exc_info()`, or *None* if no exception information is available.
- **func** (*str* | *None*) – The name of the function or method from which the logging call was invoked.
- **sinfo** (*str* | *None*) – A text string representing stack information from the base of the stack in the current thread, up to the logging call.

## getMessage()

Returns the message for this `LogRecord` instance after merging any user-supplied arguments with the message. If the user-supplied message argument to the logging call is not a string, `str()` is called on it to convert it to a string. This allows use of user-defined classes as messages, whose `__str__` method can return the actual format string to be used.

*Changed in version 3.2:* The creation of a `LogRecord` has been made more configurable by providing a factory which is used to create the record. The factory can be set using `getLogRecordFactory()` and `setLogRecordFactory()` (see this for the factory's

signature).

This functionality can be used to inject your own values into a **LogRecord** at creation time. You can use the following pattern:

```
old_factory = logging.getLogRecordFactory()

def record_factory(*args, **kwargs):
    record = old_factory(*args, **kwargs)
    record.custom_attribute = 0xdecafbad
    return record

logging.setLogRecordFactory(record_factory)
```

With this pattern, multiple factories could be chained, and as long as they don't overwrite each other's attributes or unintentionally overwrite the standard attributes listed above, there should be no surprises.

## LogRecord attributes

The LogRecord has a number of attributes, most of which are derived from the parameters to the constructor. (Note that the names do not always correspond exactly between the LogRecord constructor parameters and the LogRecord attributes.) These attributes can be used to merge data from the record into the format string. The following table lists (in alphabetical order) the attribute names, their meanings and the corresponding placeholder in a %-style format string.

If you are using {}-formatting (**str.format()**), you can use {attrname} as the placeholder in the format string. If you are using \$-formatting (**string.Template**), use the form \${attrname}. In both cases, of course, replace attrname with the actual attribute name you want to use.

In the case of {}-formatting, you can specify formatting flags by placing them after the attribute name, separated from it with a colon. For example: a placeholder of {msecs:03d} would format

a millisecond value of 4 as 004. Refer to the [str.format\(\)](#) documentation for full details on the options available to you.

## **Attributes**

This should be merged into yourself to produce message, or a dict whose values are used for the merge (when there is only one argument, and it is a dictionary).

Approximate readable time when the **LogRecord** was created. By default this is of the form '2003-07-08 16:49:45,896' (the numbers after the comma are millisecond portion of the time).

Time when the **LogRecord** was created (as returned by [time.time\(\)](#)).

Exception (used to format this yourself, if no exception has occurred), None.

Filename portion of pathname.

Name of function containing the logging call.

Text logging level for the message ('DEBUG', 'INFO', 'WARNING', 'ERROR', 'CRITICAL').

Numeric logging level for the message (**DEBUG**, **INFO**, **WARNING**, **ERROR**, **CRITICAL**).

Source line number where the logging call was issued (if available).

The logged message, computed as msg % args. This is set when [Formatter.format\(\)](#) is invoked.

Module (name) portion of filename.

Millisecond portion of the time when the **LogRecord** was created.

The string passed in the original logging call. Merged with args to produce message, or an arbitrary object (see [Using arbitrary objects as messages](#)).

Name of the logger used to log the call.

Pathname of the source file where the logging call was issued (if available).

Process ID (if available).

Process name (if available).

Time in milliseconds when the LogRecord was created, relative to the time the logging module was loaded.

Stack frame information (if available) from the bottom of the stack in the current thread, up to and including the stack frame of the logging call which resulted in the creation of this

record.

~~ThreadId (if available).~~

---

~~ProcessName (if available).~~

---

*Changed in version 3.1:* `processName` was added.

## LoggerAdapter Objects

**LoggerAdapter** instances are used to conveniently pass contextual information into logging calls. For a usage example, see the section on [adding contextual information to your logging output](#).

*class* logging.LoggerAdapter(*logger*, *extra*)

Returns an instance of **LoggerAdapter** initialized with an underlying **Logger** instance and a dict-like object.

*process*(*msg*, *kwargs*)

Modifies the message and/or keyword arguments passed to a logging call in order to insert contextual information. This implementation takes the object passed as *extra* to the constructor and adds it to *kwargs* using key 'extra'. The return value is a (*msg*, *kwargs*) tuple which has the (possibly modified) versions of the arguments passed in.

In addition to the above, **LoggerAdapter** supports the following methods of **Logger**: `debug()`, `info()`, `warning()`, `error()`, `exception()`, `critical()`, `log()`, `isEnabledFor()`, `getEffectiveLevel()`, `setLevel()` and `hasHandlers()`. These methods have the same signatures as their counterparts in **Logger**, so you can use the two types of instances interchangeably.

*Changed in version 3.2:* The `isEnabledFor()`, `getEffectiveLevel()`, `setLevel()` and `hasHandlers()` methods were added to **LoggerAdapter**. These methods delegate to the underlying logger.

*Changed in version 3.6:* Attribute **manager** and method `_log()`

were added, which delegate to the underlying logger and allow adapters to be nested.

## Thread Safety

The logging module is intended to be thread-safe without any special work needing to be done by its clients. It achieves this though using threading locks; there is one lock to serialize access to the module's shared data, and each handler also creates a lock to serialize access to its underlying I/O.

If you are implementing asynchronous signal handlers using the `signal` module, you may not be able to use logging from within such handlers. This is because lock implementations in the `threading` module are not always re-entrant, and so cannot be invoked from such signal handlers.

## Module-Level Functions

In addition to the classes described above, there are a number of module-level functions.

`logging.getLogger(name=None)`

Return a logger with the specified name or, if name is `None`, return a logger which is the root logger of the hierarchy. If specified, the name is typically a dot-separated hierarchical name like `'a'`, `'a.b'` or `'a.b.c.d'`. Choice of these names is entirely up to the developer who is using logging.

All calls to this function with a given name return the same logger instance. This means that logger instances never need to be passed between different parts of an application.

`logging.getLoggerClass()`

Return either the standard `Logger` class, or the last class passed to `setLoggerClass()`. This function may be called from within a new class definition, to ensure that installing a customized `Logger` class will not undo customizations

already applied by other code. For example:

```
class MyLogger(logging.getLoggerClass()):  
    # ... override behaviour here
```

`logging.getLogRecordFactory()`

Return a callable which is used to create a [LogRecord](#).

*New in version 3.2:* This function has been provided, along with [setLogRecordFactory\(\)](#), to allow developers more control over how the [LogRecord](#) representing a logging event is constructed.

See [setLogRecordFactory\(\)](#) for more information about the how the factory is called.

`logging.debug(msg, *args, **kwargs)`

Logs a message with level **DEBUG** on the root logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are three keyword arguments in *kwargs* which are inspected: *exc\_info* which, if it does not evaluate as false, causes exception information to be added to the logging message. If an exception tuple (in the format returned by [sys.exc\\_info\(\)](#)) or an exception instance is provided, it is used; otherwise, [sys.exc\\_info\(\)](#) is called to get the exception information.

The second optional keyword argument is *stack\_info*, which defaults to `False`. If true, stack information is added to the logging message, including the actual logging call. Note that this is not the same stack information as that displayed through specifying *exc\_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while

searching for exception handlers.

You can specify *stack\_info* independently of *exc\_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback (most recent call last):` which is used when displaying exception frames.

The third optional keyword argument is *extra* which can be used to pass a dictionary which is used to populate the `_dict_` of the `LogRecord` created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)s %(clientip)-15s %(user)-8s %('
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logging.warning('Protocol problem: %s', 'connection
```

would print something like:

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs  Protoc
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the [Formatter](#) documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the [Formatter](#) has been set up with a format string which expects ‘clientip’ and ‘user’ in the attribute dictionary of the `LogRecord`. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized **Formatter**s would be used with particular **Handlers**.

This function (as well as **info()**, **warning()**, **error()** and **critical()**) will call **basicConfig()** if the root logger doesn't have any handler attached.

*Changed in version 3.2:* The `stack_info` parameter was added.

`logging.info(msg, *args, **kwargs)`

Logs a message with level **INFO** on the root logger. The arguments are interpreted as for **debug()**.

`logging.warning(msg, *args, **kwargs)`

Logs a message with level **WARNING** on the root logger. The arguments are interpreted as for **debug()**.

### Note

There is an obsolete function `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

`logging.error(msg, *args, **kwargs)`

Logs a message with level **ERROR** on the root logger. The arguments are interpreted as for **debug()**.

`logging.critical(msg, *args, **kwargs)`

Logs a message with level **CRITICAL** on the root logger. The arguments are interpreted as for **debug()**.

`logging.exception(msg, *args, **kwargs)`

Logs a message with level **ERROR** on the root logger. The arguments are interpreted as for `debug()`. Exception info is added to the logging message. This function should only be called from an exception handler.

`logging.log(level, msg, *args, **kwargs)`

Logs a message with level *level* on the root logger. The other arguments are interpreted as for `debug()`.

`logging.disable(level=CRITICAL)`

Provides an overriding level *level* for all loggers which takes precedence over the logger's own level. When the need arises to temporarily throttle logging output down across the whole application, this function can be useful. Its effect is to disable all logging calls of severity *level* and below, so that if you call it with a value of INFO, then all INFO and DEBUG events would be discarded, whereas those of severity WARNING and above would be processed according to the logger's effective level. If `logging.disable(logging.NOTSET)` is called, it effectively removes this overriding level, so that logging output again depends on the effective levels of individual loggers.

Note that if you have defined any custom logging level higher than `CRITICAL` (this is not recommended), you won't be able to rely on the default value for the *level* parameter, but will have to explicitly supply a suitable value.

*Changed in version 3.7:* The *level* parameter was defaulted to level `CRITICAL`. See [bpo-28524](https://bugs.python.org/issue?@action=redirect&bpo=28524) [https://bugs.python.org/issue?@action=redirect&bpo=28524] for more information about this change.

`logging.addLevelName(level, levelName)`

Associates level *level* with text *levelName* in an internal dictionary, which is used to map numeric levels to a textual representation, for example when a **Formatter** formats a

message. This function can also be used to define your own levels. The only constraints are that all levels used must be registered using this function, levels should be positive integers and they should increase in increasing order of severity.

### Note

If you are thinking of defining your own levels, please see the section on [Custom Levels](#).

### `logging.getLevelNamesMapping()`

Returns a mapping from level names to their corresponding logging levels. For example, the string “CRITICAL” maps to **CRITICAL**. The returned mapping is copied from an internal mapping on each call to this function.

*New in version 3.11.*

### `logging.getLevelName(level)`

Returns the textual or numeric representation of logging level *level*.

If *level* is one of the predefined levels **CRITICAL**, **ERROR**, **WARNING**, **INFO** or **DEBUG** then you get the corresponding string. If you have associated levels with names using [addLevelName\(\)](#) then the name you have associated with *level* is returned. If a numeric value corresponding to one of the defined levels is passed in, the corresponding string representation is returned.

The *level* parameter also accepts a string representation of the level such as ‘INFO’. In such cases, this functions returns the corresponding numeric value of the level.

If no matching numeric or string value is passed in, the string ‘Level %s’ % level is returned.

## Note

Levels are internally integers (as they need to be compared in the logging logic). This function is used to convert between an integer level and the level name displayed in the formatted log output by means of the `%(levelname)s` format specifier (see [LogRecord attributes](#)), and vice versa.

*Changed in version 3.4:* In Python versions earlier than 3.4, this function could also be passed a text level, and would return the corresponding numeric value of the level. This undocumented behaviour was considered a mistake, and was removed in Python 3.4, but reinstated in 3.4.2 due to retain backward compatibility.

`logging.makeLogRecord(attrdict)`

Creates and returns a new [LogRecord](#) instance whose attributes are defined by *attrdict*. This function is useful for taking a pickled [LogRecord](#) attribute dictionary, sent over a socket, and reconstituting it as a [LogRecord](#) instance at the receiving end.

`logging.basicConfig(**kwargs)`

Does basic configuration for the logging system by creating a [StreamHandler](#) with a default [Formatter](#) and adding it to the root logger. The functions `debug()`, `info()`, `warning()`, `error()` and `critical()` will call [basicConfig\(\)](#) automatically if no handlers are defined for the root logger.

This function does nothing if the root logger already has handlers configured, unless the keyword argument *force* is set to `True`.

## Note

This function should be called from the main thread before other threads are started. In versions of Python prior to 2.7.1 and 3.2, if this function is called from multiple

threads, it is possible (in rare circumstances) that a handler will be added to the root logger more than once, leading to unexpected results such as messages being duplicated in the log.

The following keyword arguments are supported.

### Description

**Specifies** that a **FileHandler** be created, using the specified filename, rather than a **StreamHandler**.

**filename** is specified, open the file in this **mode**. Defaults to 'a'.

**format** the specified format string for the handler. Defaults to attributes `levelname`, `name` and `message` separated by colons.

**datefmt** the specified date/time format, as accepted by **time.strftime()**.

**format** is specified, use this style for the format string.

One of '%', '{' or '\$' for **printf-style**, **str.format()** or **string.Template** respectively. Defaults to '%'.  
**level** the root logger level to the specified **level**.

**stream** the specified stream to initialize the

**StreamHandler**. Note that this argument is incompatible with **filename** - if both are present, a `ValueError` is raised.

**handlers** if specified, this should be an iterable of already created handlers to add to the root logger. Any handlers which don't already have a formatter set will be assigned the default formatter created in this function. Note that this argument is incompatible with **filename** or **stream** - if both are present, a `ValueError` is raised.

**flush** if this keyword argument is specified as true, any existing handlers attached to the root logger are removed and closed, before carrying out the configuration as specified by the other arguments.

**formatter** keyword argument is specified along with **filename**, its value is used when the **FileHandler** is created, and thus used when opening the output file.

**error\_formatter** keyword argument is specified along with **filename**, its value is used when the **FileHandler** is created, and

thus used when opening the output file. If not specified, the value 'backslashreplace' is used. Note that if `None` is specified, it will be passed as such to `open()`, which means that it will be treated the same as passing 'errors'.

---

*Changed in version 3.2:* The *style* argument was added.

*Changed in version 3.3:* The *handlers* argument was added. Additional checks were added to catch situations where incompatible arguments are specified (e.g. *handlers* together with *stream* or *filename*, or *stream* together with *filename*).

*Changed in version 3.8:* The *force* argument was added.

*Changed in version 3.9:* The *encoding* and *errors* arguments were added.

## `logging.shutdown()`

Informs the logging system to perform an orderly shutdown by flushing and closing all handlers. This should be called at application exit and no further use of the logging system should be made after this call.

When the logging module is imported, it registers this function as an exit handler (see `atexit`), so normally there's no need to do that manually.

## `logging.setLoggerClass(klass)`

Tells the logging system to use the class *klass* when instantiating a logger. The class should define `__init__()` such that only a name argument is required, and the `__init__()` should call `Logger.__init__()`. This function is typically called before any loggers are instantiated by applications which need to use custom logger behavior. After this call, as at any other time, do not instantiate loggers directly using the subclass: continue to use the `logging.getLogger()` API to get your loggers.

## `logging.setLogRecordFactory(factory)`

Set a callable which is used to create a [LogRecord](#).

## Parameters

**factory** – The factory callable to be used to instantiate a log record.

*New in version 3.2:* This function has been provided, along with [getLogRecordFactory\(\)](#), to allow developers more control over how the [LogRecord](#) representing a logging event is constructed.

The factory has the following signature:

```
factory(name, level, fn, lno, msg, args,
exc_info, func=None, sinfo=None, **kwargs)
```

**name**

The logger name.

**level**

The logging level  
(numeric).

**fn**

The full pathname of the  
file where the logging  
call was made.

**lno**

The line number in the  
file where the logging  
call was made.

**msg**

The logging message.

**args**

The arguments for the  
logging message.

**exc\_info**

An exception tuple, or  
None.

**func**

The name of the function  
or method which

|               |                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>sinfo</b>  | invoked the logging call.<br><br>A stack traceback such as is provided by <code>traceback.print_stack()</code> , showing the call hierarchy. |
| <b>kwargs</b> | Additional keyword arguments.                                                                                                                |

## Module-Level Attributes

### `logging.lastResort`

A “handler of last resort” is available through this attribute. This is a `StreamHandler` writing to `sys.stderr` with a level of `WARNING`, and is used to handle logging events in the absence of any logging configuration. The end result is to just print the message to `sys.stderr`. This replaces the earlier error message saying that “no handlers could be found for logger XYZ”. If you need the earlier behaviour for some reason, `lastResort` can be set to `None`.

*New in version 3.2.*

## Integration with the warnings module

The `captureWarnings()` function can be used to integrate `logging` with the `warnings` module.

### `logging.captureWarnings(capture)`

This function is used to turn the capture of warnings by logging on and off.

If `capture` is `True`, warnings issued by the `warnings` module will be redirected to the logging system. Specifically, a warning will be formatted using `warnings.formatwarning()` and the resulting string

logged to a logger named `'py.warnings'` with a severity of **WARNING**.

If `capture` is `False`, the redirection of warnings to the logging system will stop, and warnings will be redirected to their original destinations (i.e. those in effect before `captureWarnings(True)` was called).

- [Logging Cookbook](#)

---

This section describes the API for configuring the logging module.

## Configuration functions

The following functions configure the logging module. They are located in the `logging.config` module. Their use is optional — you can configure the logging module using these functions or by making calls to the main API (defined in `logging` itself) and defining handlers which are declared either in `logging` or `logging.handlers`.

`logging.config.dictConfig(config)`

Takes the logging configuration from a dictionary. The contents of this dictionary are described in [Configuration dictionary schema](#) below.

If an error is encountered during configuration, this function will raise a `ValueError`, `TypeError`, `AttributeError` or `ImportError` with a suitably descriptive message. The

following is a (possibly incomplete) list of conditions which will raise an error:

- A `level` which is not a string or which is a string not corresponding to an actual logging level.
- A `propagate` value which is not a boolean.
- An `id` which does not have a corresponding destination.
- A non-existent handler `id` found during an incremental call.
- An invalid logger name.
- Inability to resolve to an internal or external object.

Parsing is performed by the **DictConfigurator** class, whose constructor is passed the dictionary used for configuration, and has a **configure()** method. The **logging.config** module has a callable attribute **dictConfigClass** which is initially set to **DictConfigurator**. You can replace the value of **dictConfigClass** with a suitable implementation of your own.

**dictConfig()** calls **dictConfigClass** passing the specified dictionary, and then calls the **configure()** method on the returned object to put the configuration into effect:

```
def dictConfig(config):  
    dictConfigClass(config).configure()
```

For example, a subclass of **DictConfigurator** could call **DictConfigurator.\_\_init\_\_()** in its own **\_\_init\_\_()**, then set up custom prefixes which would be usable in the subsequent **configure()** call. **dictConfigClass** would be bound to this new subclass, and then **dictConfig()** could be called exactly as in the default, uncustomized state.

*New in version 3.2.*

`logging.config.fileConfig(fname, defaults=None,`

*disable\_existing\_loggers = True, encoding = None)*

Reads the logging configuration from a `configparser`-format file. The format of the file should be as described in [Configuration file format](#). This function can be called several times from an application, allowing an end user to select from various pre-canned configurations (if the developer provides a mechanism to present the choices and load the chosen configuration).

It will raise `FileNotFoundError` if the file doesn't exist and `RuntimeError` if the file is invalid or empty.

### Parameters

- **fname** – A filename, or a file-like object, or an instance derived from `RawConfigParser`. If a `RawConfigParser`-derived instance is passed, it is used as is. Otherwise, a `Configparser` is instantiated, and the configuration read by it from the object passed in `fname`. If that has a `readline()` method, it is assumed to be a file-like object and read using `read_file()`; otherwise, it is assumed to be a filename and passed to `read()`.
- **defaults** – Defaults to be passed to the `ConfigParser` can be specified in this argument.
- **disable\_existing\_loggers** – If specified as `False`, loggers which exist when this call is made are left enabled. The default is `True` because this enables old behaviour in a backward-compatible way. This behaviour is to disable any existing non-root loggers unless they or their ancestors are explicitly named in the logging configuration.
- **encoding** – The encoding used to open

file when *fname* is filename.

*Changed in version 3.4:* An instance of a subclass of `RawConfigParser` is now accepted as a value for `fname`. This facilitates:

- Use of a configuration file where logging configuration is just part of the overall application configuration.
- Use of a configuration read from a file, and then modified by the using application (e.g. based on command-line parameters or other aspects of the runtime environment) before being passed to `fileConfig`.

*New in version 3.10:* The *encoding* parameter is added.

*Changed in version 3.11.4:* An exception will be thrown if the provided file doesn't exist or is invalid or empty.

`logging.config.listen(port=DEFAULT_LOGGING_CONFIG_PORT,  
verify=None)`

Starts up a socket server on the specified port, and listens for new configurations. If no port is specified, the module's default `DEFAULT_LOGGING_CONFIG_PORT` is used. Logging configurations will be sent as a file suitable for processing by `dictConfig()` or `fileConfig()`. Returns a `Thread` instance on which you can call `start()` to start the server, and which you can `join()` when appropriate. To stop the server, call `stopListening()`.

The `verify` argument, if specified, should be a callable which should verify whether bytes received across the socket are valid and should be processed. This could be done by encrypting and/or signing what is sent across the socket, such that the `verify` callable can perform signature verification and/or decryption. The `verify` callable is called with a single argument - the bytes received across the socket - and should return the bytes to be processed, or `None` to indicate

that the bytes should be discarded. The returned bytes could be the same as the passed in bytes (e.g. when only verification is done), or they could be completely different (perhaps if decryption were performed).

To send a configuration to the socket, read in the configuration file and send it to the socket as a sequence of bytes preceded by a four-byte length string packed in binary using `struct.pack('>L', n)`.

### Note

Because portions of the configuration are passed through `eval()`, use of this function may open its users to a security risk. While the function only binds to a socket on `localhost`, and so does not accept connections from remote machines, there are scenarios where untrusted code could be run under the account of the process which calls `listen()`. Specifically, if the process calling `listen()` runs on a multi-user machine where users cannot trust each other, then a malicious user could arrange to run essentially arbitrary code in a victim user's process, simply by connecting to the victim's `listen()` socket and sending a configuration which runs whatever code the attacker wants to have executed in the victim's process. This is especially easy to do if the default port is used, but not hard even if a different port is used. To avoid the risk of this happening, use the `verify` argument to `listen()` to prevent unrecognised configurations from being applied.

*Changed in version 3.4:* The `verify` argument was added.

### Note

If you want to send configurations to the listener which don't disable existing loggers, you will need to use a JSON format for the configuration, which will use `dictConfig()` for configuration. This method allows you to specify `disable_existing_loggers` as `False` in

the configuration you send.

`logging.config.stopListening()`

Stops the listening server which was created with a call to `listen()`. This is typically called before calling `join()` on the return value from `listen()`.

## Security considerations

The logging configuration functionality tries to offer convenience, and in part this is done by offering the ability to convert text in configuration files into Python objects used in logging configuration - for example, as described in [User-defined objects](#). However, these same mechanisms (importing callables from user-defined modules and calling them with parameters from the configuration) could be used to invoke any code you like, and for this reason you should treat configuration files from untrusted sources with *extreme caution* and satisfy yourself that nothing bad can happen if you load them, before actually loading them.

## Configuration dictionary schema

Describing a logging configuration requires listing the various objects to create and the connections between them; for example, you may create a handler named ‘console’ and then say that the logger named ‘startup’ will send its messages to the ‘console’ handler. These objects aren’t limited to those provided by the `logging` module because you might write your own formatter or handler class. The parameters to these classes may also need to include external objects such as `sys.stderr`. The syntax for describing these objects and connections is defined in [Object connections](#) below.

### Dictionary Schema Details

The dictionary passed to `dictConfig()` must contain the following keys:

- *version* - to be set to an integer value representing the schema version. The only valid value at present is 1, but having this key allows the schema to evolve while still preserving backwards compatibility.

All other keys are optional, but if present they will be interpreted as described below. In all cases below where a 'configuring dict' is mentioned, it will be checked for the special '()' key to see if a custom instantiation is required. If so, the mechanism described in [User-defined objects](#) below is used to create an instance; otherwise, the context is used to determine what to instantiate.

- *formatters* - the corresponding value will be a dict in which each key is a formatter id and each value is a dict describing how to configure the corresponding [Formatter](#) instance.

The configuring dict is searched for the following optional keys which correspond to the arguments passed to create a [Formatter](#) object:

- `format`
- `datefmt`
- `style`
- `validate` (since version  $\geq 3.8$ )

An optional `class` key indicates the name of the formatter's class (as a dotted module and class name). The instantiation arguments are as for [Formatter](#), thus this key is most useful for instantiating a customised subclass of [Formatter](#). For example, the alternative class might present exception tracebacks in an expanded or condensed format. If your formatter requires different or extra configuration keys, you should use [User-defined objects](#).

- *filters* - the corresponding value will be a dict in which each key is a filter id and each value is a dict describing how to configure the corresponding Filter instance.

The configuring dict is searched for the key `name` (defaulting to the empty string) and this is used to construct a [logging.Filter](#) instance.

- *handlers* - the corresponding value will be a dict in which each key is a handler id and each value is a dict describing how to configure the corresponding Handler instance.

The configuring dict is searched for the following keys:

- `class` (mandatory). This is the fully qualified name of the handler class.
- `level` (optional). The level of the handler.
- `formatter` (optional). The id of the formatter for this handler.
- `filters` (optional). A list of ids of the filters for this handler.

*Changed in version 3.11:* `filters` can take filter instances in addition to ids.

All *other* keys are passed through as keyword arguments to the handler's constructor. For example, given the snippet:

```
handlers:
  console:
    class : logging.StreamHandler
    formatter: brief
    level   : INFO
    filters: [allow_foo]
    stream  : ext://sys.stdout
  file:
    class : logging.handlers.RotatingFileHandler
    formatter: precise
    filename: logconfig.log
    maxBytes: 1024
    backupCount: 3
```

the handler with id `console` is instantiated as a **logging.StreamHandler**, using `sys.stdout` as the underlying stream. The handler with id `file` is instantiated as a **logging.handlers.RotatingFileHandler** with

the keyword arguments `filename='logconfig.log', maxBytes=1024, backupCount=3`.

- *loggers* - the corresponding value will be a dict in which each key is a logger name and each value is a dict describing how to configure the corresponding Logger instance.

The configuring dict is searched for the following keys:

- `level` (optional). The level of the logger.
- `propagate` (optional). The propagation setting of the logger.
- `filters` (optional). A list of ids of the filters for this logger.

*Changed in version 3.11:* `filters` can take filter instances in addition to ids.

- `handlers` (optional). A list of ids of the handlers for this logger.

The specified loggers will be configured according to the level, propagation, filters and handlers specified.

- *root* - this will be the configuration for the root logger. Processing of the configuration will be as for any logger, except that the `propagate` setting will not be applicable.
- *incremental* - whether the configuration is to be interpreted as incremental to the existing configuration. This value defaults to `False`, which means that the specified configuration replaces the existing configuration with the same semantics as used by the existing `fileConfig()` API.

If the specified value is `True`, the configuration is processed as described in the section on [Incremental Configuration](#).

- *disable\_existing\_loggers* - whether any existing non-root loggers are to be disabled. This setting mirrors the parameter of the same name in `fileConfig()`. If absent, this parameter

defaults to `True`. This value is ignored if *incremental* is `True`.

## Incremental Configuration

It is difficult to provide complete flexibility for incremental configuration. For example, because objects such as filters and formatters are anonymous, once a configuration is set up, it is not possible to refer to such anonymous objects when augmenting a configuration.

Furthermore, there is not a compelling case for arbitrarily altering the object graph of loggers, handlers, filters, formatters at run-time, once a configuration is set up; the verbosity of loggers and handlers can be controlled just by setting levels (and, in the case of loggers, propagation flags). Changing the object graph arbitrarily in a safe way is problematic in a multi-threaded environment; while not impossible, the benefits are not worth the complexity it adds to the implementation.

Thus, when the `incremental` key of a configuration dict is present and is `True`, the system will completely ignore any `formatters` and `filters` entries, and process only the `level` settings in the `handlers` entries, and the `level` and `propagate` settings in the `loggers` and `root` entries.

Using a value in the configuration dict lets configurations to be sent over the wire as pickled dicts to a socket listener. Thus, the logging verbosity of a long-running application can be altered over time with no need to stop and restart the application.

## Object connections

The schema describes a set of logging objects - loggers, handlers, formatters, filters - which are connected to each other in an object graph. Thus, the schema needs to represent connections between the objects. For example, say that, once configured, a particular logger has attached to it a particular handler. For the purposes of this discussion, we can say that the logger represents the source, and the handler the destination, of a connection between the two.

Of course in the configured objects this is represented by the logger holding a reference to the handler. In the configuration dict, this is done by giving each destination object an id which identifies it unambiguously, and then using the id in the source object's configuration to indicate that a connection exists between the source and the destination object with that id.

So, for example, consider the following YAML snippet:

```
formatters:
  brief:
    # configuration for formatter with id 'brief' goes here
  precise:
    # configuration for formatter with id 'precise' goes here
handlers:
  h1: #This is an id
    # configuration of handler with id 'h1' goes here
    formatter: brief
  h2: #This is another id
    # configuration of handler with id 'h2' goes here
    formatter: precise
loggers:
  foo.bar.baz:
    # other configuration for logger 'foo.bar.baz'
    handlers: [h1, h2]
```

(Note: YAML used here because it's a little more readable than the equivalent Python source form for the dictionary.)

The ids for loggers are the logger names which would be used programmatically to obtain a reference to those loggers, e.g. `foo.bar.baz`. The ids for Formatters and Filters can be any string value (such as `brief`, `precise` above) and they are transient, in that they are only meaningful for processing the configuration dictionary and used to determine connections between objects, and are not persisted anywhere when the configuration call is complete.

The above snippet indicates that logger named `foo.bar.baz` should have two handlers attached to it, which are described by the handler ids `h1` and `h2`. The formatter for `h1` is that described by

id `brief`, and the formatter for `h2` is that described by `id precise`.

## User-defined objects

The schema supports user-defined objects for handlers, filters and formatters. (Loggers do not need to have different types for different instances, so there is no support in this configuration schema for user-defined logger classes.)

Objects to be configured are described by dictionaries which detail their configuration. In some places, the logging system will be able to infer from the context how an object is to be instantiated, but when a user-defined object is to be instantiated, the system will not know how to do this. In order to provide complete flexibility for user-defined object instantiation, the user needs to provide a ‘factory’ - a callable which is called with a configuration dictionary and which returns the instantiated object. This is signalled by an absolute import path to the factory being made available under the special key `'()'`. Here’s a concrete example:

```
formatters:
  brief:
    format: '%(message)s'
  default:
    format: '%(asctime)s %(levelname)-8s %(name)-15s %(message)s'
    datefmt: '%Y-%m-%d %H:%M:%S'
  custom:
    (): my.package.customFormatterFactory
    bar: baz
    spam: 99.9
    answer: 42
```

The above YAML snippet defines three formatters. The first, with id `brief`, is a standard `logging.Formatter` instance with the specified format string. The second, with id `default`, has a longer format and also defines the time format explicitly, and will result in a `logging.Formatter` initialized with those two format strings. Shown in Python source form, the `brief` and `default` formatters have configuration sub-dictionaries:

```
{
    'format' : '%(message)s'
}
```

and:

```
{
    'format' : '%(asctime)s %(levelname)-8s %(name)-15s %'
    'datefmt' : '%Y-%m-%d %H:%M:%S'
}
```

respectively, and as these dictionaries do not contain the special key '()', the instantiation is inferred from the context: as a result, standard `logging.Formatter` instances are created. The configuration sub-dictionary for the third formatter, with id `custom`, is:

```
{
    '()' : 'my.package.customFormatterFactory',
    'bar' : 'baz',
    'spam' : 99.9,
    'answer' : 42
}
```

and this contains the special key '()', which means that user-defined instantiation is wanted. In this case, the specified factory callable will be used. If it is an actual callable it will be used directly - otherwise, if you specify a string (as in the example) the actual callable will be located using normal import mechanisms. The callable will be called with the **remaining** items in the configuration sub-dictionary as keyword arguments. In the above example, the formatter with id `custom` will be assumed to be returned by the call:

```
my.package.customFormatterFactory(bar='baz', spam=99.9,
```

## Warning

The values for keys such as `bar`, `spam` and `answer` in the above example should not be configuration dictionaries or

references such as `cfg://foo` or `ext://bar`, because they will not be processed by the configuration machinery, but passed to the callable as-is.

The key `'()'` has been used as the special key because it is not a valid keyword parameter name, and so will not clash with the names of the keyword arguments used in the call. The `'()'` also serves as a mnemonic that the corresponding value is a callable.

*Changed in version 3.11:* The `filters` member of `handlers` and `loggers` can take filter instances in addition to ids.

You can also specify a special key `'.'` whose value is a dictionary is a mapping of attribute names to values. If found, the specified attributes will be set on the user-defined object before it is returned. Thus, with the following configuration:

```
{
    '()' : 'my.package.customFormatterFactory',
    'bar' : 'baz',
    'spam' : 99.9,
    'answer' : 42,
    '.' : {
        'foo': 'bar',
        'baz': 'bozz'
    }
}
```

the returned formatter will have attribute `foo` set to `'bar'` and attribute `baz` set to `'bozz'`.

## Warning

The values for attributes such as `foo` and `baz` in the above example should not be configuration dictionaries or references such as `cfg://foo` or `ext://bar`, because they will not be processed by the configuration machinery, but set as attribute values as-is.

## Handler configuration order

Handlers are configured in alphabetical order of their keys, and a configured handler replaces the configuration dictionary in (a working copy of) the `handlers` dictionary in the schema. If you use a construct such as `cfg://handlers.foo`, then initially `handlers['foo']` points to the configuration dictionary for the handler named `foo`, and later (once that handler has been configured) it points to the configured handler instance. Thus, `cfg://handlers.foo` could resolve to either a dictionary or a handler instance. In general, it is wise to name handlers in a way such that dependent handlers are configured after any handlers they depend on; that allows something like `cfg://handlers.foo` to be used in configuring a handler that depends on handler `foo`. If that dependent handler were named `bar`, problems would result, because the configuration of `bar` would be attempted before that of `foo`, and `foo` would not yet have been configured. However, if the dependent handler were named `foobar`, it would be configured after `foo`, with the result that `cfg://handlers.foo` would resolve to configured handler `foo`, and not its configuration dictionary.

## Access to external objects

There are times where a configuration needs to refer to objects external to the configuration, for example `sys.stderr`. If the configuration dict is constructed using Python code, this is straightforward, but a problem arises when the configuration is provided via a text file (e.g. JSON, YAML). In a text file, there is no standard way to distinguish `sys.stderr` from the literal string `'sys.stderr'`. To facilitate this distinction, the configuration system looks for certain special prefixes in string values and treat them specially. For example, if the literal string `'ext://sys.stderr'` is provided as a value in the configuration, then the `ext://` will be stripped off and the remainder of the value processed using normal import mechanisms.

The handling of such prefixes is done in a way analogous to protocol handling: there is a generic mechanism to look for prefixes which match the regular expression `^(?P<prefix>[a-z]+)://`

(?P<suffix>.\*)\$ whereby, if the `prefix` is recognised, the `suffix` is processed in a prefix-dependent manner and the result of the processing replaces the string value. If the `prefix` is not recognised, then the string value will be left as-is.

## Access to internal objects

As well as external objects, there is sometimes also a need to refer to objects in the configuration. This will be done implicitly by the configuration system for things that it knows about. For example, the string value `'DEBUG'` for a `level` in a logger or handler will automatically be converted to the value `logging.DEBUG`, and the `handlers`, `filters` and `formatter` entries will take an object id and resolve to the appropriate destination object.

However, a more generic mechanism is needed for user-defined objects which are not known to the `logging` module. For example, consider `logging.handlers.MemoryHandler`, which takes a `target` argument which is another handler to delegate to. Since the system already knows about this class, then in the configuration, the given `target` just needs to be the object id of the relevant target handler, and the system will resolve to the handler from the id. If, however, a user defines a `my.package.MyHandler` which has an `alternate` handler, the configuration system would not know that the `alternate` referred to a handler. To cater for this, a generic resolution system allows the user to specify:

```
handlers:
  file:
    # configuration of file handler goes here

  custom:
    (): my.package.MyHandler
    alternate: cfg://handlers.file
```

The literal string `'cfg://handlers.file'` will be resolved in an analogous way to strings with the `ext://` prefix, but looking in the configuration itself rather than the import namespace. The mechanism allows access by dot or by index, in a similar way to

that provided by `str.format`. Thus, given the following snippet:

```
handlers:
  email:
    class: logging.handlers.SMTPHandler
    mailhost: localhost
    fromaddr: my_app@domain.tld
    toaddrs:
      - support_team@domain.tld
      - dev_team@domain.tld
    subject: Houston, we have a problem.
```

in the configuration, the string `'cfg://handlers'` would resolve to the dict with key `handlers`, the string `'cfg://handlers.email'` would resolve to the dict with key `email` in the `handlers` dict, and so on. The string `'cfg://handlers.email.toaddrs[1]'` would resolve to `'dev_team@domain.tld'` and the string `'cfg://handlers.email.toaddrs[0]'` would resolve to the value `'support_team@domain.tld'`. The `subject` value could be accessed using either `'cfg://handlers.email.subject'` or, equivalently, `'cfg://handlers.email[subject]'`. The latter form only needs to be used if the key contains spaces or non-alphanumeric characters. If an index value consists only of decimal digits, access will be attempted using the corresponding integer value, falling back to the string value if needed.

Given a string `cfg://handlers.myhandler.mykey.123`, this will resolve to `config_dict['handlers']['myhandler']['mykey']['123']`. If the string is specified as `cfg://handlers.myhandler.mykey[123]`, the system will attempt to retrieve the value from `config_dict['handlers']['myhandler']['mykey'][123]`, and fall back to `config_dict['handlers']['myhandler']['mykey']['123']` if that fails.

## Import resolution and custom importers

Import resolution, by default, uses the builtin `__import__()` function to do its importing. You may want to replace this with

your own importing mechanism: if so, you can replace the **importer** attribute of the **DictConfigurator** or its superclass, the **BaseConfigurator** class. However, you need to be careful because of the way functions are accessed from classes via descriptors. If you are using a Python callable to do your imports, and you want to define it at class level rather than instance level, you need to wrap it with `staticmethod()`. For example:

```
from importlib import import_module
from logging.config import BaseConfigurator

BaseConfigurator.importer = staticmethod(import_module)
```

You don't need to wrap with `staticmethod()` if you're setting the import callable on a configurator *instance*.

## Configuration file format

The configuration file format understood by `fileConfig()` is based on `configparser` functionality. The file must contain sections called `[loggers]`, `[handlers]` and `[formatters]` which identify by name the entities of each type which are defined in the file. For each such entity, there is a separate section which identifies how that entity is configured. Thus, for a logger named `log01` in the `[loggers]` section, the relevant configuration details are held in a section `[logger_log01]`. Similarly, a handler called `hand01` in the `[handlers]` section will have its configuration held in a section called `[handler_hand01]`, while a formatter called `form01` in the `[formatters]` section will have its configuration specified in a section called `[formatter_form01]`. The root logger configuration must be specified in a section called `[logger_root]`.

### Note

The `fileConfig()` API is older than the `dictConfig()` API and does not provide functionality to cover certain aspects of logging. For example, you cannot configure **Filter** objects, which provide for filtering of messages beyond simple integer

levels, using `fileConfig()`. If you need to have instances of `Filter` in your logging configuration, you will need to use `dictConfig()`. Note that future enhancements to configuration functionality will be added to `dictConfig()`, so it's worth considering transitioning to this newer API when it's convenient to do so.

Examples of these sections in the file are given below.

```
[loggers]
keys=root,log02,log03,log04,log05,log06,log07
```

```
[handlers]
keys=hand01,hand02,hand03,hand04,hand05,hand06,hand07,ha
```

```
[formatters]
keys=form01,form02,form03,form04,form05,form06,form07,fo
```

The root logger must specify a level and a list of handlers. An example of a root logger section is given below.

```
[logger_root]
level=NOTSET
handlers=hand01
```

The `level` entry can be one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL` or `NOTSET`. For the root logger only, `NOTSET` means that all messages will be logged. Level values are [evaluated](#) in the context of the `logging` package's namespace.

The `handlers` entry is a comma-separated list of handler names, which must appear in the `[handlers]` section. These names must appear in the `[handlers]` section and have corresponding sections in the configuration file.

For loggers other than the root logger, some additional information is required. This is illustrated by the following example.

```
[logger_parser]
level=DEBUG
```

```
handlers=hand01
propagate=1
qualname=compiler.parser
```

The `level` and `handlers` entries are interpreted as for the root logger, except that if a non-root logger's level is specified as `NOTSET`, the system consults loggers higher up the hierarchy to determine the effective level of the logger. The `propagate` entry is set to 1 to indicate that messages must propagate to handlers higher up the logger hierarchy from this logger, or 0 to indicate that messages are **not** propagated to handlers up the hierarchy. The `qualname` entry is the hierarchical channel name of the logger, that is to say the name used by the application to get the logger.

Sections which specify handler configuration are exemplified by the following.

```
[handler_hand01]
class=StreamHandler
level=NOTSET
formatter=form01
args=(sys.stdout,)
```

The `class` entry indicates the handler's class (as determined by `eval()` in the logging package's namespace). The `level` is interpreted as for loggers, and `NOTSET` is taken to mean 'log everything'.

The `formatter` entry indicates the key name of the formatter for this handler. If blank, a default formatter (`logging._defaultFormatter`) is used. If a name is specified, it must appear in the `[formatters]` section and have a corresponding section in the configuration file.

The `args` entry, when **evaluated** in the context of the logging package's namespace, is the list of arguments to the constructor for the handler class. Refer to the constructors for the relevant handlers, or to the examples below, to see how typical entries are constructed. If not provided, it defaults to `()`.

The optional `kwargs` entry, when **evaluated** in the context of the

logging package's namespace, is the keyword argument dict to the constructor for the handler class. If not provided, it defaults to {}.

```
[handler_hand02]  
class=FileHandler  
level=DEBUG  
formatter=form02  
args=('python.log', 'w')
```

```
[handler_hand03]  
class=handlers.SocketHandler  
level=INFO  
formatter=form03  
args=('localhost', handlers.DEFAULT_TCP_LOGGING_PORT)
```

```
[handler_hand04]  
class=handlers.DatagramHandler  
level=WARN  
formatter=form04  
args=('localhost', handlers.DEFAULT_UDP_LOGGING_PORT)
```

```
[handler_hand05]  
class=handlers.SysLogHandler  
level=ERROR  
formatter=form05  
args= (('localhost', handlers.SYSLOG_UDP_PORT), handlers.
```

```
[handler_hand06]  
class=handlers.NTEventLogHandler  
level=CRITICAL  
formatter=form06  
args=('Python Application', '', 'Application')
```

```
[handler_hand07]  
class=handlers.SMTPHandler  
level=WARN  
formatter=form07  
args=('localhost', 'from@abc', ['user1@abc', 'user2@xyz'  
kwargs={'timeout': 10.0}
```

```
[handler_hand08]
class=handlers.MemoryHandler
level=NOTSET
formatter=form08
target=
args=(10, ERROR)

[handler_hand09]
class=handlers.HTTPHandler
level=NOTSET
formatter=form09
args=('localhost:9022', '/log', 'GET')
kwargs={'secure': True}
```

Sections which specify formatter configuration are typified by the following.

```
[formatter_form01]
format=F1 %(asctime)s %(levelname)s %(message)s
datefmt=
style=%
validate=True
class=logging.Formatter
```

The arguments for the formatter configuration are the same as the keys in the dictionary schema [formatters section](#).

## Note

Due to the use of [eval\(\)](#) as described above, there are potential security risks which result from using the [listen\(\)](#) to send and receive configurations via sockets. The risks are limited to where multiple users with no mutual trust run code on the same machine; see the [listen\(\)](#) documentation for more information.

# logging.handlers — Logging handlers

**Source code:** [Lib/logging/handlers.py](https://github.com/python/cpython/tree/3.11/Lib/logging/handlers.py) [https://github.com/python/cpython/tree/3.11/Lib/logging/handlers.py]

## Important

This page contains only reference information. For tutorials, please see

- [Basic Tutorial](#)
  - [Advanced Tutorial](#)
  - [Logging Cookbook](#)
- 

The following useful handlers are provided in the package. Note that three of the handlers ([StreamHandler](#), [FileHandler](#) and [NullHandler](#)) are actually defined in the [logging](#) module itself, but have been documented here along with the other handlers.

## StreamHandler

The [StreamHandler](#) class, located in the core [logging](#) package, sends logging output to streams such as `sys.stdout`, `sys.stderr` or any file-like object (or, more precisely, any object which supports `write()` and `flush()` methods).

`class logging.StreamHandler(stream=None)`

Returns a new instance of the [StreamHandler](#) class. If `stream` is specified, the instance will use it for logging output; otherwise, `sys.stderr` will be used.

`emit(record)`

If a formatter is specified, it is used to format the

record. The record is then written to the stream followed by `terminator`. If exception information is present, it is formatted using `traceback.print_exception()` and appended to the stream.

## `flush()`

Flushes the stream by calling its `flush()` method. Note that the `close()` method is inherited from `Handler` and so does no output, so an explicit `flush()` call may be needed at times.

## `setStream(stream)`

Sets the instance's stream to the specified value, if it is different. The old stream is flushed before the new stream is set.

### Parameters

**stream** – The stream that the handler should use.

### Returns

the old stream, if the stream was changed, or *None* if it wasn't.

*New in version 3.7.*

## `terminator`

String used as the terminator when writing a formatted record to a stream. Default value is `'\n'`.

If you don't want a newline termination, you can set the handler instance's `terminator` attribute to the empty string.

In earlier versions, the terminator was hardcoded as `'\n'`.

*New in version 3.2.*

# FileHandler

The `FileHandler` class, located in the core `logging` package, sends logging output to a disk file. It inherits the output functionality from `StreamHandler`.

```
class logging.FileHandler(filename, mode='a', encoding=None,
delay=False, errors=None)
```

Returns a new instance of the `FileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, `'a'` is used. If `encoding` is not `None`, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely. If `errors` is specified, it's used to determine how encoding errors are handled.

*Changed in version 3.6:* As well as string values, `Path` objects are also accepted for the `filename` argument.

*Changed in version 3.9:* The `errors` parameter was added.

```
close()
```

Closes the file.

```
emit(record)
```

Outputs the record to the file.

Note that if the file was closed due to logging shutdown at exit and the file mode is `'w'`, the record will not be emitted (see [bpo-42378](https://bugs.python.org/issue42378) [https://bugs.python.org/issue?@action=redirect&bpo=42378]).

# NullHandler

*New in version 3.1.*

The `NullHandler` class, located in the core `logging` package, does not do any formatting or output. It is essentially a 'no-op'

handler for use by library developers.

*class* logging.NullHandler

Returns a new instance of the **NullHandler** class.

*emit(record)*

This method does nothing.

*handle(record)*

This method does nothing.

*createLock()*

This method returns `None` for the lock, since there is no underlying I/O to which access needs to be serialized.

See [Configuring Logging for a Library](#) for more information on how to use **NullHandler**.

## WatchedFileHandler

The **WatchedFileHandler** class, located in the **logging.handlers** module, is a **FileHandler** which watches the file it is logging to. If the file changes, it is closed and reopened using the file name.

A file change can happen because of usage of programs such as *newsyslog* and *logrotate* which perform log file rotation. This handler, intended for use under Unix/Linux, watches the file to see if it has changed since the last emit. (A file is deemed to have changed if its device or inode have changed.) If the file has changed, the old file stream is closed, and the file opened to get a new stream.

This handler is not appropriate for use under Windows, because under Windows open log files cannot be moved or renamed - logging opens the files with exclusive locks - and so there is no need for such a handler. Furthermore, *ST\_INO* is not supported under

Windows; `stat()` always returns zero for this value.

`class logging.handlers.WatchedFileHandler(filename, mode='a', encoding=None, delay=False, errors=None)`

Returns a new instance of the `WatchedFileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, `'a'` is used. If `encoding` is not `None`, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely. If `errors` is provided, it determines how encoding errors are handled.

*Changed in version 3.6:* As well as string values, `Path` objects are also accepted for the `filename` argument.

*Changed in version 3.9:* The `errors` parameter was added.

`reopenIfNeeded()`

Checks to see if the file has changed. If it has, the existing stream is flushed and closed and the file opened again, typically as a precursor to outputting the record to the file.

*New in version 3.6.*

`emit(record)`

Outputs the record to the file, but first calls `reopenIfNeeded()` to reopen the file if it has changed.

## BaseRotatingHandler

The `BaseRotatingHandler` class, located in the `logging.handlers` module, is the base class for the rotating file handlers, `RotatingFileHandler` and `TimedRotatingFileHandler`. You should not need to instantiate this class, but it has attributes and methods you may need to override.

`class logging.handlers.BaseRotatingHandler(filename, mode,  
encoding=None, delay=False, errors=None)`

The parameters are as for **FileHandler**. The attributes are:

**namer**

If this attribute is set to a callable, the `rotation_filename()` method delegates to this callable. The parameters passed to the callable are those passed to `rotation_filename()`.

### Note

The namer function is called quite a few times during rollover, so it should be as simple and as fast as possible. It should also return the same output every time for a given input, otherwise the rollover behaviour may not work as expected.

It's also worth noting that care should be taken when using a namer to preserve certain attributes in the filename which are used during rotation. For example, `RotatingFileHandler` expects to have a set of log files whose names contain successive integers, so that rotation works as expected, and `TimedRotatingFileHandler` deletes old log files (based on the `backupCount` parameter passed to the handler's initializer) by determining the oldest files to delete. For this to happen, the filenames should be sortable using the date/time portion of the filename, and a namer needs to respect this. (If a namer is wanted that doesn't respect this scheme, it will need to be used in a subclass of `TimedRotatingFileHandler` which overrides the `getFilesToDelete()` method to fit in with the custom naming scheme.)

*New in version 3.3.*

**rotator**

If this attribute is set to a callable, the `rotate()` method delegates to this callable. The parameters passed to the callable are those passed to `rotate()`.

*New in version 3.3.*

`rotation_filename(default_name)`

Modify the filename of a log file when rotating.

This is provided so that a custom filename can be provided.

The default implementation calls the ‘namer’ attribute of the handler, if it’s callable, passing the default name to it. If the attribute isn’t callable (the default is `None`), the name is returned unchanged.

#### Parameters

**default\_name** – The default name for the log file.

*New in version 3.3.*

`rotate(source, dest)`

When rotating, rotate the current log.

The default implementation calls the ‘rotator’ attribute of the handler, if it’s callable, passing the source and dest arguments to it. If the attribute isn’t callable (the default is `None`), the source is simply renamed to the destination.

#### Parameters

- **source** – The source filename. This is normally the base filename, e.g. ‘test.log’.
- **dest** – The destination filename. This is normally what the source is rotated to, e.g. ‘test.log.1’.

*New in version 3.3.*

The reason the attributes exist is to save you having to subclass - you can use the same callables for instances of `RotatingFileHandler` and `TimedRotatingFileHandler`. If either the namer or rotator callable raises an exception, this will be handled in the same way as any other exception during an `emit()` call, i.e. via the `handleError()` method of the handler.

If you need to make more significant changes to rotation processing, you can override the methods.

For an example, see [Using a rotator and namer to customize log rotation processing](#).

## RotatingFileHandler

The `RotatingFileHandler` class, located in the `logging.handlers` module, supports rotation of disk log files.

```
class logging.handlers.RotatingFileHandler(filename, mode='a',
maxBytes=0, backupCount=0, encoding=None, delay=False,
errors=None)
```

Returns a new instance of the `RotatingFileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, `'a'` is used. If `encoding` is not `None`, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely. If `errors` is provided, it determines how encoding errors are handled.

You can use the `maxBytes` and `backupCount` values to allow the file to *rollover* at a predetermined size. When the size is about to be exceeded, the file is closed and a new file is silently opened for output. Rollover occurs whenever the current log file is nearly `maxBytes` in length; but if either of `maxBytes` or `backupCount` is zero, rollover never occurs, so you generally want to set `backupCount` to at least 1, and have a non-zero `maxBytes`. When `backupCount` is non-zero, the system

will save old log files by appending the extensions `‘.1’`, `‘.2’` etc., to the filename. For example, with a *backupCount* of 5 and a base file name of `app.log`, you would get `app.log`, `app.log.1`, `app.log.2`, up to `app.log.5`. The file being written to is always `app.log`. When this file is filled, it is closed and renamed to `app.log.1`, and if files `app.log.1`, `app.log.2`, etc. exist, then they are renamed to `app.log.2`, `app.log.3` etc. respectively.

*Changed in version 3.6:* As well as string values, **Path** objects are also accepted for the *filename* argument.

*Changed in version 3.9:* The *errors* parameter was added.

`doRollover()`

Does a rollover, as described above.

`emit(record)`

Outputs the record to the file, catering for rollover as described previously.

## TimedRotatingFileHandler

The **TimedRotatingFileHandler** class, located in the **logging.handlers** module, supports rotation of disk log files at certain timed intervals.

*class logging.handlers.TimedRotatingFileHandler(filename, when = 'h', interval = 1, backupCount = 0, encoding = None, delay = False, utc = False, atTime = None, errors = None)*

Returns a new instance of the **TimedRotatingFileHandler** class. The specified file is opened and used as the stream for logging. On rotating it also sets the filename suffix. Rotating happens based on the product of *when* and *interval*.

You can use the *when* to specify the type of *interval*. The list of possible values is below. Note that they are not case sensitive.

---

## Types of *interval*s used

---

Seconds

---

Minutes

---

Hours

---

Days

---

Weekday (0=Monday) rollover time

---

Rollover computed initially from *rolloverTime* specified, else at time *atTime*

---

When using weekday-based rotation, specify ‘W0’ for Monday, ‘W1’ for Tuesday, and so on up to ‘W6’ for Sunday. In this case, the value passed for *interval* isn’t used.

The system will save old log files by appending extensions to the filename. The extensions are date-and-time based, using the strftime format `%Y-%m-%d_%H-%M-%S` or a leading portion thereof, depending on the rollover interval.

When computing the next rollover time for the first time (when the handler is created), the last modification time of an existing log file, or else the current time, is used to compute when the next rotation will occur.

If the *utc* argument is true, times in UTC will be used; otherwise local time is used.

If *backupCount* is nonzero, at most *backupCount* files will be kept, and if more would be created when rollover occurs, the oldest one is deleted. The deletion logic uses the interval to determine which files to delete, so changing the interval may leave old files lying around.

If *delay* is true, then file opening is deferred until the first call to `emit()`.

If *atTime* is not `None`, it must be a `datetime.time` instance which specifies the time of day when rollover occurs, for the cases where rollover is set to happen “at midnight” or “on a particular weekday”. Note that in these cases, the *atTime* value is effectively used to compute the *initial* rollover, and subsequent rollovers would be calculated via the normal

interval calculation.

If *errors* is specified, it's used to determine how encoding errors are handled.

### **Note**

Calculation of the initial rollover time is done when the handler is initialised. Calculation of subsequent rollover times is done only when rollover occurs, and rollover occurs only when emitting output. If this is not kept in mind, it might lead to some confusion. For example, if an interval of “every minute” is set, that does not mean you will always see log files with times (in the filename) separated by a minute; if, during application execution, logging output is generated more frequently than once a minute, *then* you can expect to see log files with times separated by a minute. If, on the other hand, logging messages are only output once every five minutes (say), then there will be gaps in the file times corresponding to the minutes where no output (and hence no rollover) occurred.

*Changed in version 3.4:* *atTime* parameter was added.

*Changed in version 3.6:* As well as string values, **Path** objects are also accepted for the *filename* argument.

*Changed in version 3.9:* The *errors* parameter was added.

`doRollover()`

Does a rollover, as described above.

`emit(record)`

Outputs the record to the file, catering for rollover as described above.

`getFilesToDelete()`

Returns a list of filenames which should be deleted as

part of rollover. These are the absolute paths of the oldest backup log files written by the handler.

## SocketHandler

The `SocketHandler` class, located in the `logging.handlers` module, sends logging output to a network socket. The base class uses a TCP socket.

*class* logging.handlers.SocketHandler(*host*, *port*)

Returns a new instance of the `SocketHandler` class intended to communicate with a remote machine whose address is given by *host* and *port*.

*Changed in version 3.4:* If *port* is specified as `None`, a Unix domain socket is created using the value in *host* - otherwise, a TCP socket is created.

`close()`

Closes the socket.

`emit()`

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. If the connection was previously lost, re-establishes the connection. To unpickle the record at the receiving end into a `LogRecord`, use the `makeLogRecord()` function.

`handleError()`

Handles an error which has occurred during `emit()`. The most likely cause is a lost connection. Closes the socket so that we can retry on the next event.

`makeSocket()`

This is a factory method which allows subclasses to define the precise type of socket they want. The default

implementation creates a TCP socket  
(`socket.SOCK_STREAM`).

### `makePickle(record)`

Pickles the record's attribute dictionary in binary format with a length prefix, and returns it ready for transmission across the socket. The details of this operation are equivalent to:

```
data = pickle.dumps(record_attr_dict, 1)
datalen = struct.pack('>L', len(data))
return datalen + data
```

Note that pickles aren't completely secure. If you are concerned about security, you may want to override this method to implement a more secure mechanism. For example, you can sign pickles using HMAC and then verify them on the receiving end, or alternatively you can disable unpickling of global objects on the receiving end.

### `send(packet)`

Send a pickled byte-string *packet* to the socket. The format of the sent byte-string is as described in the documentation for `makePickle()`.

This function allows for partial sends, which can happen when the network is busy.

### `createSocket()`

Tries to create a socket; on failure, uses an exponential back-off algorithm. On initial failure, the handler will drop the message it was trying to send. When subsequent messages are handled by the same instance, it will not try connecting until some time has passed. The default parameters are such that the initial delay is one second, and if after that delay the connection still can't be made, the handler will double the delay each time up to a maximum of 30 seconds.

This behaviour is controlled by the following handler attributes:

- `retryStart` (initial delay, defaulting to 1.0 seconds).
- `retryFactor` (multiplier, defaulting to 2.0).
- `retryMax` (maximum delay, defaulting to 30.0 seconds).

This means that if the remote listener starts up *after* the handler has been used, you could lose messages (since the handler won't even attempt a connection until the delay has elapsed, but just silently drop messages during the delay period).

## DatagramHandler

The `DatagramHandler` class, located in the `logging.handlers` module, inherits from `SocketHandler` to support sending logging messages over UDP sockets.

*class* `logging.handlers.DatagramHandler(host, port)`

Returns a new instance of the `DatagramHandler` class intended to communicate with a remote machine whose address is given by *host* and *port*.

### Note

As UDP is not a streaming protocol, there is no persistent connection between an instance of this handler and *host*. For this reason, when using a network socket, a DNS lookup might have to be made each time an event is logged, which can introduce some latency into the system. If this affects you, you can do a lookup yourself and initialize this handler using the looked-up IP address rather than the hostname.

*Changed in version 3.4:* If `port` is specified as `None`, a Unix domain socket is created using the value in `host` -

otherwise, a UDP socket is created.

`emit()`

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. To unpickle the record at the receiving end into a `LogRecord`, use the `makeLogRecord()` function.

`makeSocket()`

The factory method of `SocketHandler` is here overridden to create a UDP socket (`socket.SOCK_DGRAM`).

`send(s)`

Send a pickled byte-string to a socket. The format of the sent byte-string is as described in the documentation for `SocketHandler.makePickle()`.

## SysLogHandler

The `SysLogHandler` class, located in the `logging.handlers` module, supports sending logging messages to a remote or local Unix syslog.

```
class logging.handlers.SysLogHandler(address=('localhost',
SYSLOG_UDP_PORT), facility=LOG_USER,
socktype=socket.SOCK_DGRAM)
```

Returns a new instance of the `SysLogHandler` class intended to communicate with a remote Unix machine whose address is given by `address` in the form of a `(host, port)` tuple. If `address` is not specified, `('localhost', 514)` is used. The address is used to open a socket. An alternative to providing a `(host, port)` tuple is providing an address as a string, for example  `'/dev/log'`. In this case, a Unix domain socket is used to send the message to the syslog. If `facility` is not specified, `LOG_USER` is used. The type of socket opened

depends on the *socktype* argument, which defaults to `socket.SOCK_DGRAM` and thus opens a UDP socket. To open a TCP socket (for use with the newer syslog daemons such as rsyslog), specify a value of `socket.SOCK_STREAM`.

Note that if your server is not listening on UDP port 514, `SysLogHandler` may appear not to work. In that case, check what address you should be using for a domain socket - it's system dependent. For example, on Linux it's usually `‘/dev/log’` but on OS/X it's `‘/var/run/syslog’`. You'll need to check your platform and use the appropriate address (you may need to do this check at runtime if your application needs to run on several platforms). On Windows, you pretty much have to use the UDP option.

### Note

On macOS 12.x (Monterey), Apple has changed the behaviour of their syslog daemon - it no longer listens on a domain socket. Therefore, you cannot expect `SysLogHandler` to work on this system.

See [gh-91070](https://github.com/python/cpython/issues/91070) [<https://github.com/python/cpython/issues/91070>] for more information.

*Changed in version 3.2: socktype was added.*

`close()`

Closes the socket to the remote host.

`createSocket()`

Tries to create a socket and, if it's not a datagram socket, connect it to the other end. This method is called during handler initialization, but it's not regarded as an error if the other end isn't listening at this point - the method will be called again when emitting an event, if but it's not regarded as an error if the other end isn't listening yet — the method will be called again when emitting an event, if there is no

socket at that point.

*New in version 3.11.*

`emit(record)`

The record is formatted, and then sent to the syslog server. If exception information is present, it is *not* sent to the server.

*Changed in version 3.2.1:* (See: [bpo-12168](https://bugs.python.org/issue/?@action=redirect&bpo=12168) [https://bugs.python.org/issue/?@action=redirect&bpo=12168].) In earlier versions, the message sent to the syslog daemons was always terminated with a NUL byte, because early versions of these daemons expected a NUL terminated message - even though it's not in the relevant specification ([RFC 5424](https://datatracker.ietf.org/doc/html/rfc5424.html) [https://datatracker.ietf.org/doc/html/rfc5424.html]). More recent versions of these daemons don't expect the NUL byte but strip it off if it's there, and even more recent daemons (which adhere more closely to RFC 5424) pass the NUL byte on as part of the message.

To enable easier handling of syslog messages in the face of all these differing daemon behaviours, the appending of the NUL byte has been made configurable, through the use of a class-level attribute, `append_nul`. This defaults to `True` (preserving the existing behaviour) but can be set to `False` on a `SysLogHandler` instance in order for that instance to *not* append the NUL terminator.

*Changed in version 3.3:* (See: [bpo-12419](https://bugs.python.org/issue/?@action=redirect&bpo=12419) [https://bugs.python.org/issue/?@action=redirect&bpo=12419].) In earlier versions, there was no facility for an “ident” or “tag” prefix to identify the source of the message. This can now be specified using a class-level attribute, defaulting to `""` to preserve existing behaviour, but which can be overridden on a `SysLogHandler` instance in order for that instance to prepend the ident to every message handled. Note that the provided ident

must be text, not bytes, and is prepended to the message exactly as is.

`encodePriority(facility, priority)`

Encodes the facility and priority into an integer. You can pass in strings or integers - if strings are passed, internal mapping dictionaries are used to convert them to integers.

The symbolic `LOG_` values are defined in [SysLogHandler](#) and mirror the values defined in the `sys/syslog.h` header file.

## Priorities

| Symbol (string)          | Integer |
|--------------------------|---------|
| <code>LOG_ALERT</code>   | 7       |
| <code>LOG_CRIT</code>    | 4       |
| <code>LOG_DEBUG</code>   | 0       |
| <code>LOG_EMERG</code>   | 1       |
| <code>LOG_ERR</code>     | 3       |
| <code>LOG_INFO</code>    | 6       |
| <code>LOG_NOTICE</code>  | 5       |
| <code>LOG_WARNING</code> | 2       |

## Facilities

| Symbol (string)           | Integer |
|---------------------------|---------|
| <code>LOG_AUTH</code>     | 16      |
| <code>LOG_AUTHPRIV</code> | 20      |
| <code>LOG_CRON</code>     | 18      |
| <code>LOG_DAEMON</code>   | 7       |
| <code>LOG_FTP</code>      | 21      |
| <code>LOG_KERN</code>     | 0       |
| <code>LOG_LPR</code>      | 11      |
| <code>LOG_MAIL</code>     | 14      |
| <code>LOG_NEWS</code>     | 17      |
| <code>LOG_SYSLOG</code>   | 3       |
| <code>LOG_USER</code>     | 4       |
| <code>LOG_UUCP</code>     | 9       |

|            |
|------------|
| LOG_LOCAL0 |
| LOG_LOCAL1 |
| LOG_LOCAL2 |
| LOG_LOCAL3 |
| LOG_LOCAL4 |
| LOG_LOCAL5 |
| LOG_LOCAL6 |
| LOG_LOCAL7 |

`mapPriority(levelname)`

Maps a logging level name to a syslog priority name. You may need to override this if you are using custom levels, or if the default algorithm is not suitable for your needs. The default algorithm maps `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL` to the equivalent syslog names, and all other level names to 'warning'.

## NTEventLogHandler

The `NTEventLogHandler` class, located in the `logging.handlers` module, supports sending logging messages to a local Windows NT, Windows 2000 or Windows XP event log. Before you can use it, you need Mark Hammond's Win32 extensions for Python installed.

`class logging.handlers.NTEventLogHandler(appname,  
dllname = None, logtype = 'Application')`

Returns a new instance of the `NTEventLogHandler` class. The *appname* is used to define the application name as it appears in the event log. An appropriate registry entry is created using this name. The *dllname* should give the fully qualified pathname of a .dll or .exe which contains message definitions to hold in the log (if not specified, 'win32service.pyd' is used - this is installed with the Win32 extensions and contains some basic placeholder message definitions. Note that use of these placeholders will make your event logs big, as the entire message source is held in the log. If you want slimmer logs, you have to pass in the

name of your own .dll or .exe which contains the message definitions you want to use in the event log). The *logtype* is one of 'Application', 'System' or 'Security', and defaults to 'Application'.

close()

At this point, you can remove the application name from the registry as a source of event log entries. However, if you do this, you will not be able to see the events as you intended in the Event Log Viewer - it needs to be able to access the registry to get the .dll name. The current version does not do this.

emit(*record*)

Determines the message ID, event category and event type, and then logs the message in the NT event log.

getEventCategory(*record*)

Returns the event category for the record. Override this if you want to specify your own categories. This version returns 0.

getEventType(*record*)

Returns the event type for the record. Override this if you want to specify your own types. This version does a mapping using the handler's *typemap* attribute, which is set up in `__init__()` to a dictionary which contains mappings for **DEBUG**, **INFO**, **WARNING**, **ERROR** and **CRITICAL**. If you are using your own levels, you will either need to override this method or place a suitable dictionary in the handler's *typemap* attribute.

getMessageID(*record*)

Returns the message ID for the record. If you are using your own messages, you could do this by having the *msg* passed to the logger being an ID rather than a

format string. Then, in here, you could use a dictionary lookup to get the message ID. This version returns 1, which is the base message ID in `win32service.pyd`.

## SMTPHandler

The `SMTPHandler` class, located in the `logging.handlers` module, supports sending logging messages to an email address via SMTP.

`class logging.handlers.SMTPHandler(mailhost, fromaddr, toaddrs, subject, credentials = None, secure = None, timeout = 1.0)`

Returns a new instance of the `SMTPHandler` class. The instance is initialized with the from and to addresses and subject line of the email. The *toaddrs* should be a list of strings. To specify a non-standard SMTP port, use the (host, port) tuple format for the *mailhost* argument. If you use a string, the standard SMTP port is used. If your SMTP server requires authentication, you can specify a (username, password) tuple for the *credentials* argument.

To specify the use of a secure protocol (TLS), pass in a tuple to the *secure* argument. This will only be used when authentication credentials are supplied. The tuple should be either an empty tuple, or a single-value tuple with the name of a keyfile, or a 2-value tuple with the names of the keyfile and certificate file. (This tuple is passed to the `smtpplib.SMTP.starttls()` method.)

A timeout can be specified for communication with the SMTP server using the *timeout* argument.

*New in version 3.3:* The *timeout* argument was added.

`emit(record)`

Formats the record and sends it to the specified addressees.

`getSubject(record)`

If you want to specify a subject line which is record-dependent, override this method.

## MemoryHandler

The `MemoryHandler` class, located in the `logging.handlers` module, supports buffering of logging records in memory, periodically flushing them to a *target* handler. Flushing occurs whenever the buffer is full, or when an event of a certain severity or greater is seen.

`MemoryHandler` is a subclass of the more general `BufferingHandler`, which is an abstract class. This buffers logging records in memory. Whenever each record is added to the buffer, a check is made by calling `shouldFlush()` to see if the buffer should be flushed. If it should, then `flush()` is expected to do the flushing.

`class logging.handlers.BufferingHandler(capacity)`

Initializes the handler with a buffer of the specified capacity. Here, *capacity* means the number of logging records buffered.

`emit(record)`

Append the record to the buffer. If `shouldFlush()` returns true, call `flush()` to process the buffer.

`flush()`

You can override this to implement custom flushing behavior. This version just zaps the buffer to empty.

`shouldFlush(record)`

Return `True` if the buffer is up to capacity. This method can be overridden to implement custom flushing strategies.

`class logging.handlers.MemoryHandler(capacity, flushLevel=ERROR, target=None, flushOnClose=True)`

Returns a new instance of the `MemoryHandler` class. The instance is initialized with a buffer size of *capacity* (number of records buffered). If *flushLevel* is not specified, `ERROR` is used. If no *target* is specified, the target will need to be set using `setTarget()` before this handler does anything useful. If *flushOnClose* is specified as `False`, then the buffer is *not* flushed when the handler is closed. If not specified or specified as `True`, the previous behaviour of flushing the buffer will occur when the handler is closed.

*Changed in version 3.6:* The *flushOnClose* parameter was added.

`close()`

Calls `flush()`, sets the target to `None` and clears the buffer.

`flush()`

For a `MemoryHandler`, flushing means just sending the buffered records to the target, if there is one. The buffer is also cleared when this happens. Override if you want different behavior.

`setTarget(target)`

Sets the target handler for this handler.

`shouldFlush(record)`

Checks for buffer full or a record at the *flushLevel* or higher.

## HTTPHandler

The `HTTPHandler` class, located in the `logging.handlers` module, supports sending logging messages to a web server, using either `GET` or `POST` semantics.

`class logging.handlers.HTTPHandler(host, url, method='GET',`

*secure=False, credentials=None, context=None)*

Returns a new instance of the `HTTPHandler` class. The *host* can be of the form `host:port`, should you need to use a specific port number. If no *method* is specified, `GET` is used. If *secure* is true, a HTTPS connection will be used. The *context* parameter may be set to a `ssl.SSLContext` instance to configure the SSL settings used for the HTTPS connection. If *credentials* is specified, it should be a 2-tuple consisting of *userid* and *password*, which will be placed in a HTTP 'Authorization' header using Basic authentication. If you specify *credentials*, you should also specify *secure=True* so that your *userid* and *password* are not passed in cleartext across the wire.

*Changed in version 3.5:* The *context* parameter was added.

`mapLogRecord(record)`

Provides a dictionary, based on *record*, which is to be URL-encoded and sent to the web server. The default implementation just returns `record.__dict__`. This method can be overridden if e.g. only a subset of `LogRecord` is to be sent to the web server, or if more specific customization of what's sent to the server is required.

`emit(record)`

Sends the record to the web server as a URL-encoded dictionary. The `mapLogRecord()` method is used to convert the record to the dictionary to be sent.

## Note

Since preparing a record for sending it to a web server is not the same as a generic formatting operation, using `setFormatter()` to specify a `Formatter` for a `HTTPHandler` has no effect. Instead of calling `format()`, this handler calls `mapLogRecord()` and then `urllib.parse.urlencode()` to encode the dictionary in a form suitable for sending to a web server.

# QueueHandler

*New in version 3.2.*

The `QueueHandler` class, located in the `logging.handlers` module, supports sending logging messages to a queue, such as those implemented in the `queue` or `multiprocessing` modules.

Along with the `QueueListener` class, `QueueHandler` can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via `SMTPHandler`) are done on a separate thread.

`class logging.handlers.QueueHandler(queue)`

Returns a new instance of the `QueueHandler` class. The instance is initialized with the queue to send messages to. The `queue` can be any queue-like object; it's used as-is by the `enqueue()` method, which needs to know how to send messages to it. The queue is not *required* to have the task tracking API, which means that you can use `SimpleQueue` instances for `queue`.

## Note

If you are using `multiprocessing`, you should avoid using `SimpleQueue` and instead use `multiprocessing.Queue`.

`emit(record)`

Enqueues the result of preparing the `LogRecord`. Should an exception occur (e.g. because a bounded queue has filled up), the `handleError()` method is called to handle the error. This can result in the record silently being dropped (if `logging.raiseExceptions` is `False`) or a message printed to `sys.stderr` (if

`logging.raiseExceptions` is `True`).

### `prepare(record)`

Prepares a record for queuing. The object returned by this method is enqueued.

The base implementation formats the record to merge the message, arguments, exception and stack information, if present. It also removes unpickleable items from the record in-place. Specifically, it overwrites the record's `msg` and `message` attributes with the merged message (obtained by calling the handler's `format()` method), and sets the `args`, `exc_info` and `exc_text` attributes to `None`.

You might want to override this method if you want to convert the record to a dict or JSON string, or send a modified copy of the record while leaving the original intact.

### Note

The base implementation formats the message with arguments, sets the `message` and `msg` attributes to the formatted message and sets the `args` and `exc_text` attributes to `None` to allow pickling and to prevent further attempts at formatting. This means that a handler on the `QueueListener` side won't have the information to do custom formatting, e.g. of exceptions. You may wish to subclass `QueueHandler` and override this method to e.g. avoid setting `exc_text` to `None`. Note that the `message` / `msg` / `args` changes are related to ensuring the record is pickleable, and you might or might not be able to avoid doing that depending on whether your `args` are pickleable. (Note that you may have to consider not only your own code but also code in any libraries that you use.)

`enqueue(record)`

Enqueues the record on the queue using `put_nowait()`; you may want to override this if you want to use blocking behaviour, or a timeout, or a customized queue implementation.

## QueueListener

*New in version 3.2.*

The `QueueListener` class, located in the `logging.handlers` module, supports receiving logging messages from a queue, such as those implemented in the `queue` or `multiprocessing` modules. The messages are received from a queue in an internal thread and passed, on the same thread, to one or more handlers for processing. While `QueueListener` is not itself a handler, it is documented here because it works hand-in-hand with `QueueHandler`.

Along with the `QueueHandler` class, `QueueListener` can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via `SMTPHandler`) are done on a separate thread.

`class logging.handlers.QueueListener(queue, *handlers,  
respect_handler_level=False)`

Returns a new instance of the `QueueListener` class. The instance is initialized with the queue to send messages to and a list of handlers which will handle entries placed on the queue. The queue can be any queue-like object; it's passed as-is to the `dequeue()` method, which needs to know how to get messages from it. The queue is not *required* to have the task tracking API (though it's used if available), which means that you can use `SimpleQueue` instances for *queue*.

**Note**

If you are using `multiprocessing`, you should avoid using `SimpleQueue` and instead use `multiprocessing.Queue`.

If `respect_handler_level` is `True`, a handler's level is respected (compared with the level for the message) when deciding whether to pass messages to that handler; otherwise, the behaviour is as in previous Python versions - to always pass each message to each handler.

*Changed in version 3.5:* The `respect_handler_level` argument was added.

`dequeue(block)`

Dequeues a record and return it, optionally blocking.

The base implementation uses `get()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

`prepare(record)`

Prepare a record for handling.

This implementation just returns the passed-in record. You may want to override this method if you need to do any custom marshalling or manipulation of the record before passing it to the handlers.

`handle(record)`

Handle a record.

This just loops through the handlers offering them the record to handle. The actual object passed to the handlers is that which is returned from `prepare()`.

`start()`

Starts the listener.

This starts up a background thread to monitor the queue for LogRecords to process.

`stop()`

Stops the listener.

This asks the thread to terminate, and then waits for it to do so. Note that if you don't call this before your application exits, there may be some records still left on the queue, which won't be processed.

`enqueue_sentinel()`

Writes a sentinel to the queue to tell the listener to quit. This implementation uses `put_nowait()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

*New in version 3.3.*

Configuration API for the logging module.

# getpass — Portable password input

**Source code:** [Lib/getpass.py](https://github.com/python/cpython/tree/3.11/Lib/getpass.py) [https://github.com/python/cpython/tree/3.11/Lib/getpass.py]

---

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emsripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

The **getpass** module provides two functions:

`getpass.getpass(prompt='Password: ', stream=None)`

Prompt the user for a password without echoing. The user is prompted using the string *prompt*, which defaults to 'Password: '. On Unix, the prompt is written to the file-like object *stream* using the `replace` error handler if needed. *stream* defaults to the controlling terminal (`/dev/tty`) or if that is unavailable to `sys.stderr` (this argument is ignored on Windows).

If echo free input is unavailable `getpass()` falls back to printing a warning message to *stream* and reading from `sys.stdin` and issuing a **GetPassWarning**.

## Note

If you call `getpass` from within IDLE, the input may be done in the terminal you launched IDLE from rather than the idle window itself.

*exception* `getpass.GetPassWarning`

A **UserWarning** subclass issued when password input may be echoed.

`getpass.getuser()`

Return the “login name” of the user.

This function checks the environment variables **LOGNAME**, **USER**, **LNAME** and **USERNAME**, in order, and returns the value of the first one which is set to a non-empty string. If none are set, the login name from the password database is returned on systems which support the **pwd** module, otherwise, an exception is raised.

In general, this function should be preferred over **`os.getlogin()`**.

# **curses** — Terminal handling for character-cell displays

**Source code:** [Lib/curses](https://github.com/python/cpython/tree/3.11/Lib/curses) [https://github.com/python/cpython/tree/3.11/Lib/curses]

---

The **curses** module provides an interface to the curses library, the de-facto standard for portable advanced terminal handling.

While curses is most widely used in the Unix environment, versions are available for Windows, DOS, and possibly other systems as well. This extension module is designed to match the API of ncurses, an open-source curses library hosted on Linux and the BSD variants of Unix.

## **Note**

Whenever the documentation mentions a *character* it can be specified as an integer, a one-character Unicode string or a one-byte byte string.

Whenever the documentation mentions a *character string* it can be specified as a Unicode string or a byte string.

## Curses Programming with Python

Tutorial material on using curses with Python, by Andrew Kuchling and Eric Raymond.

The [Tools/demo/](https://github.com/python/cpython/tree/3.11/Tools/demo/) [https://github.com/python/cpython/tree/3.11/Tools/demo/] directory in the Python source distribution contains some example programs using the curses bindings provided by this module.

# Functions

The module **curses** defines the following exception:

*exception* **curses.error**

Exception raised when a curses library function returns an error.

## Note

Whenever *x* or *y* arguments to a function or a method are optional, they default to the current cursor location. Whenever *attr* is optional, it defaults to **A\_NORMAL**.

The module **curses** defines the following functions:

**curses.baudrate()**

Return the output speed of the terminal in bits per second. On software terminal emulators it will have a fixed high value. Included for historical reasons; in former times, it was used to write output loops for time delays and occasionally to change interfaces depending on the line speed.

**curses.beep()**

Emit a short attention sound.

`curses.can_change_color()`

Return `True` or `False`, depending on whether the programmer can change the colors displayed by the terminal.

`curses.cbreak()`

Enter `cbreak` mode. In `cbreak` mode (sometimes called “rare” mode) normal `tty` line buffering is turned off and characters are available to be read one by one. However, unlike `raw` mode, special characters (interrupt, quit, suspend, and flow control) retain their effects on the `tty` driver and calling program. Calling first `raw()` then `cbreak()` leaves the terminal in `cbreak` mode.

`curses.color_content(color_number)`

Return the intensity of the red, green, and blue (RGB) components in the color *color\_number*, which must be between 0 and `COLORS - 1`. Return a 3-tuple, containing the R,G,B values for the given color, which will be between 0 (no component) and 1000 (maximum amount of component).

`curses.color_pair(pair_number)`

Return the attribute value for displaying text in the specified color pair. Only the first 256 color pairs are supported. This attribute value can be combined with `A_STANDOUT`, `A_REVERSE`, and the other `A_*` attributes. `pair_number()` is the counterpart to this function.

`curses.curs_set(visibility)`

Set the cursor state. *visibility* can be set to 0, 1, or 2, for invisible, normal, or very visible. If the terminal supports the visibility requested, return the previous cursor state; otherwise raise an exception. On many terminals, the “visible” mode is an underline cursor and the “very visible” mode is a block cursor.

`curses.def_prog_mode()`

Save the current terminal mode as the “program” mode, the

mode when the running program is using curses. (Its counterpart is the “shell” mode, for when the program is not in curses.) Subsequent calls to `reset_prog_mode()` will restore this mode.

#### `curses.def_shell_mode()`

Save the current terminal mode as the “shell” mode, the mode when the running program is not using curses. (Its counterpart is the “program” mode, when the program is using curses capabilities.) Subsequent calls to `reset_shell_mode()` will restore this mode.

#### `curses.delay_output(ms)`

Insert an *ms* millisecond pause in output.

#### `curses.doupdate()`

Update the physical screen. The curses library keeps two data structures, one representing the current physical screen contents and a virtual screen representing the desired next state. The `doupdate()` ground updates the physical screen to match the virtual screen.

The virtual screen may be updated by a `noutrefresh()` call after write operations such as `addstr()` have been performed on a window. The normal `refresh()` call is simply `noutrefresh()` followed by `doupdate()`; if you have to update multiple windows, you can speed performance and perhaps reduce screen flicker by issuing `noutrefresh()` calls on all windows, followed by a single `doupdate()`.

#### `curses.echo()`

Enter echo mode. In echo mode, each character input is echoed to the screen as it is entered.

#### `curses.endwin()`

De-initialize the library, and return terminal to normal status.

## `curses.erasechar()`

Return the user's current erase character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

## `curses.filter()`

The `filter()` routine, if used, must be called before `initscr()` is called. The effect is that, during those calls, **LINES** is set to 1; the capabilities `clear`, `cup`, `cud`, `cudl`, `cuul`, `cuu`, `vpa` are disabled; and the `home` string is set to the value of `cr`. The effect is that the cursor is confined to the current line, and so are screen updates. This may be used for enabling character-at-a-time line editing without touching the rest of the screen.

## `curses.flash()`

Flash the screen. That is, change it to reverse-video and then change it back in a short interval. Some people prefer such as 'visible bell' to the audible attention signal produced by `beep()`.

## `curses.flushinp()`

Flush all input buffers. This throws away any typeahead that has been typed by the user and has not yet been processed by the program.

## `curses.getmouse()`

After `getch()` returns `KEY_MOUSE` to signal a mouse event, this method should be called to retrieve the queued mouse event, represented as a 5-tuple (`id`, `x`, `y`, `z`, `bstate`). `id` is an ID value used to distinguish multiple devices, and `x`, `y`, `z` are the event's coordinates. (`z` is currently unused.) `bstate` is an integer value whose bits will be set to indicate the type of event, and will be the bitwise OR of one or more of the following constants, where `n` is the button number from 1 to 5: `BUTTONn_PRESSED`, `BUTTONn_RELEASED`,

`BUTTONn_CLICKED`, `BUTTONn_DOUBLE_CLICKED`,  
`BUTTONn_TRIPLE_CLICKED`, `BUTTON_SHIFT`,  
`BUTTON_CTRL`, `BUTTON_ALT`.

*Changed in version 3.10:* The `BUTTON5_*` constants are now exposed if they are provided by the underlying curses library.

`curses.getsyx()`

Return the current coordinates of the virtual screen cursor as a tuple `(y, x)`. If `leaveok` is currently `True`, then return `(-1, -1)`.

`curses.getwin(file)`

Read window related data stored in the file by an earlier `window.putwin()` call. The routine then creates and initializes a new window using that data, returning the new window object.

`curses.has_colors()`

Return `True` if the terminal can display colors; otherwise, return `False`.

`curses.has_extended_color_support()`

Return `True` if the module supports extended colors; otherwise, return `False`. Extended color support allows more than 256 color pairs for terminals that support more than 16 colors (e.g. `xterm-256color`).

Extended color support requires ncurses version 6.1 or later.

*New in version 3.10.*

`curses.has_ic()`

Return `True` if the terminal has insert- and delete-character capabilities. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.has_il()`

Return `True` if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.has_key(ch)`

Take a key value *ch*, and return `True` if the current terminal type recognizes a key with that value.

`curses.halfdelay(tenths)`

Used for half-delay mode, which is similar to `cbreak` mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, raise an exception if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

`curses.init_color(color_number, r, g, b)`

Change the definition of a color, taking the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of *color\_number* must be between 0 and `COLORS - 1`. Each of *r*, *g*, *b*, must be a value between 0 and 1000. When `init_color()` is used, all occurrences of that color on the screen immediately change to the new definition. This function is a no-op on most terminals; it is active only if `can_change_color()` returns `True`.

`curses.init_pair(pair_number, fg, bg)`

Change the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of *pair\_number* must be between 1 and `COLOR_PAIRS - 1` (the 0 color pair is wired to white on black and cannot be changed). The value of *fg* and *bg* arguments must be between 0 and `COLORS - 1`, or, after

calling `use_default_colors()`, `-1`. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair are changed to the new definition.

`curses.initscr()`

Initialize the library. Return a `window` object which represents the whole screen.

### Note

If there is an error opening the terminal, the underlying `curses` library may cause the interpreter to exit.

`curses.is_term_resized(nlines, ncols)`

Return `True` if `resize_term()` would modify the window structure, `False` otherwise.

`curses.isendwin()`

Return `True` if `endwin()` has been called (that is, the `curses` library has been deinitialized).

`curses.keyname(k)`

Return the name of the key numbered *k* as a bytes object. The name of a key generating printable ASCII character is the key's character. The name of a control-key combination is a two-byte bytes object consisting of a caret (`b'^'`) followed by the corresponding printable ASCII character. The name of an alt-key combination (128–255) is a bytes object consisting of the prefix `b'M-'` followed by the name of the corresponding ASCII character.

`curses.killchar()`

Return the user's current line kill character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the `curses` program, and is not set by

the curses library itself.

`curses.longname()`

Return a bytes object containing the terminfo long name field describing the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to `initscr()`.

`curses.meta(flag)`

If *flag* is `True`, allow 8-bit characters to be input. If *flag* is `False`, allow only 7-bit chars.

`curses.mouseinterval(interval)`

Set the maximum time in milliseconds that can elapse between press and release events in order for them to be recognized as a click, and return the previous interval value. The default value is 200 milliseconds, or one fifth of a second.

`curses.mousemask(mousemask)`

Set the mouse events to be reported, and return a tuple (*availmask*, *oldmask*). *availmask* indicates which of the specified mouse events can be reported; on complete failure it returns 0. *oldmask* is the previous value of the given window's mouse event mask. If this function is never called, no mouse events are ever reported.

`curses.napms(ms)`

Sleep for *ms* milliseconds.

`curses.newpad(nlines, ncols)`

Create and return a pointer to a new pad data structure with the given number of lines and columns. Return a pad as a window object.

A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is

needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (such as from scrolling or echoing of input) do not occur. The `refresh()` and `noutrefresh()` methods of a pad require 6 arguments to specify the part of the pad to be displayed and the location on the screen to be used for the display. The arguments are *pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*; the *p* arguments refer to the upper left corner of the pad region to be displayed and the *s* arguments define a clipping box on the screen within which the pad region is to be displayed.

`curses.newwin(nlines, ncols)`

`curses.newwin(nlines, ncols, begin_y, begin_x)`

Return a new [window](#), whose left-upper corner is at (*begin\_y*, *begin\_x*), and whose height/width is *nlines*/*ncols*.

By default, the window will extend from the specified position to the lower right corner of the screen.

`curses.nl()`

Enter newline mode. This mode translates the return key into newline on input, and translates newline into return and line-feed on output. Newline mode is initially on.

`curses.nocbreak()`

Leave cbreak mode. Return to normal “cooked” mode with line buffering.

`curses.noecho()`

Leave echo mode. Echoing of input characters is turned off.

`curses.nonl()`

Leave newline mode. Disable translation of return into newline on input, and disable low-level translation of newline into newline/return on output (but this does not change the behavior of `addch(' \n')`, which always does the

equivalent of return and line feed on the virtual screen). With translation off, curses can sometimes speed up vertical motion a little; also, it will be able to detect the return key on input.

### `curses.noqiflush()`

When the **`noqiflush()`** routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done. You may want to call **`noqiflush()`** in a signal handler if you want output to continue as though the interrupt had not occurred, after the handler exits.

### `curses.noraw()`

Leave raw mode. Return to normal “cooked” mode with line buffering.

### `curses.pair_content(pair_number)`

Return a tuple `(fg, bg)` containing the colors for the requested color pair. The value of *pair\_number* must be between 0 and `COLOR_PAIRS - 1`.

### `curses.pair_number(attr)`

Return the number of the color-pair set by the attribute value *attr*. **`color_pair()`** is the counterpart to this function.

### `curses.putp(str)`

Equivalent to `tputs(str, 1, putchar)`; emit the value of a specified terminfo capability for the current terminal. Note that the output of **`putp()`** always goes to standard output.

### `curses.qiflush([flag])`

If *flag* is `False`, the effect is the same as calling **`noqiflush()`**. If *flag* is `True`, or no argument is provided, the queues will be flushed when these control characters are read.

`curses.raw()`

Enter raw mode. In raw mode, normal line buffering and processing of interrupt, quit, suspend, and flow control keys are turned off; characters are presented to curses input functions one by one.

`curses.reset_prog_mode()`

Restore the terminal to “program” mode, as previously saved by `def_prog_mode()`.

`curses.reset_shell_mode()`

Restore the terminal to “shell” mode, as previously saved by `def_shell_mode()`.

`curses.resetty()`

Restore the state of the terminal modes to what it was at the last call to `savetty()`.

`curses.resize_term(nlines, ncols)`

Backend function used by `resizeterm()`, performing most of the work; when resizing the windows, `resize_term()` blank-fills the areas that are extended. The calling application should fill in these areas with appropriate data. The **`resize_term()`** function attempts to resize all windows. However, due to the calling convention of pads, it is not possible to resize these without additional interaction with the application.

`curses.resizeterm(nlines, ncols)`

Resize the standard and current windows to the specified dimensions, and adjusts other bookkeeping data used by the curses library that record the window dimensions (in particular the SIGWINCH handler).

`curses.savetty()`

Save the current state of the terminal modes in a buffer,

usable by `resetty()`.

`curses.get_escdelay()`

Retrieves the value set by `set_escdelay()`.

*New in version 3.9.*

`curses.set_escdelay(ms)`

Sets the number of milliseconds to wait after reading an escape character, to distinguish between an individual escape character entered on the keyboard from escape sequences sent by cursor and function keys.

*New in version 3.9.*

`curses.get_tabsize()`

Retrieves the value set by `set_tabsize()`.

*New in version 3.9.*

`curses.set_tabsize(size)`

Sets the number of columns used by the curses library when converting a tab character to spaces as it adds the tab to a window.

*New in version 3.9.*

`curses.setsyx(y, x)`

Set the virtual screen cursor to y, x. If y and x are both `-1`, then `leaveok` is set `True`.

`curses.setupterm(term=None, fd=-1)`

Initialize the terminal. *term* is a string giving the terminal name, or `None`; if omitted or `None`, the value of the **TERM** environment variable will be used. *fd* is the file descriptor to which any initialization sequences will be sent; if not supplied or `-1`, the file descriptor for `sys.stdout` will be used.

`curses.start_color()`

Must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after `initscr()`.

`start_color()` initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables in the `curses` module, `COLORS` and `COLOR_PAIRS`, containing the maximum number of colors and color-pairs the terminal can support. It also restores the colors on the terminal to the values they had when the terminal was just turned on.

`curses.termattrs()`

Return a logical OR of all video attributes supported by the terminal. This information is useful when a curses program needs complete control over the appearance of the screen.

`curses.termname()`

Return the value of the environment variable `TERM`, as a bytes object, truncated to 14 characters.

`curses.tigetflag(capname)`

Return the value of the Boolean capability corresponding to the terminfo capability name *capname* as an integer. Return the value `-1` if *capname* is not a Boolean capability, or `0` if it is canceled or absent from the terminal description.

`curses.tigetnum(capname)`

Return the value of the numeric capability corresponding to the terminfo capability name *capname* as an integer. Return the value `-2` if *capname* is not a numeric capability, or `-1` if it is canceled or absent from the terminal description.

`curses.tigetstr(capname)`

Return the value of the string capability corresponding to the terminfo capability name *capname* as a bytes object. Return

None if *capname* is not a terminfo “string capability”, or is canceled or absent from the terminal description.

`curses.tparm(str[, ...])`

Instantiate the bytes object *str* with the supplied parameters, where *str* should be a parameterized string obtained from the terminfo database. E.g. `tparm(tigetstr("cup"), 5, 3)` could result in `b'\033[6;4H'`, the exact result depending on terminal type.

`curses.typeahead(fd)`

Specify that the file descriptor *fd* be used for typeahead checking. If *fd* is `-1`, then no typeahead checking is done.

The curses library does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until `refresh` or `doupdate` is called again, allowing faster response to commands typed in advance. This function allows specifying a different file descriptor for typeahead checking.

`curses.unctrl(ch)`

Return a bytes object which is a printable representation of the character *ch*. Control characters are represented as a caret followed by the character, for example as `b'^C'`. Printing characters are left as they are.

`curses.ungetch(ch)`

Push *ch* so the next `getch()` will return it.

### **Note**

Only one *ch* can be pushed before `getch()` is called.

`curses.update_lines_cols()`

Update **LINES** and **COLS**. Useful for detecting manual screen resize.

*New in version 3.5.*

`curses.unget_wch(ch)`

Push *ch* so the next `get_wch()` will return it.

### Note

Only one *ch* can be pushed before `get_wch()` is called.

*New in version 3.3.*

`curses.ungetmouse(id, x, y, z, bstate)`

Push a **KEY\_MOUSE** event onto the input queue, associating the given state data with it.

`curses.use_env(flag)`

If used, this function should be called before `initscr()` or `newterm` are called. When *flag* is `False`, the values of lines and columns specified in the terminfo database will be used, even if environment variables **LINES** and **COLUMNS** (used by default) are set, or if `curses` is running in a window (in which case default behavior would be to use the window size if **LINES** and **COLUMNS** are not set).

`curses.use_default_colors()`

Allow use of default values for colors on terminals supporting this feature. Use this to support transparency in your application. The default color is assigned to the color number `-1`. After calling this function, `init_pair(x, curses.COLOR_RED, -1)` initializes, for instance, color pair *x* to a red foreground color on the default background.

`curses.wrapper(func, /, *args, **kwargs)`

Initialize `curses` and call another callable object, *func*, which

should be the rest of your curses-using application. If the application raises an exception, this function will restore the terminal to a sane state before re-raising the exception and generating a traceback. The callable object *func* is then passed the main window 'stdscr' as its first argument, followed by any other arguments passed to **wrapper()**. Before calling *func*, **wrapper()** turns on cbreak mode, turns off echo, enables the terminal keypad, and initializes colors if the terminal has color support. On exit (whether normally or by exception) it restores cooked mode, turns on echo, and disables the terminal keypad.

## Window Objects

Window objects, as returned by **initscr()** and **newwin()** above, have the following methods and attributes:

`window.addch(ch[, attr])`

`window.addch(y, x, ch[, attr])`

Paint character *ch* at (*y*, *x*) with attributes *attr*, overwriting any character previously painted at that location. By default, the character position and attributes are the current settings for the window object.

### Note

Writing outside the window, subwindow, or pad raises a **curses.error**. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the character is printed.

`window.addnstr(str, n[, attr])`

`window.addnstr(y, x, str, n[, attr])`

Paint at most *n* characters of the character string *str* at (*y*, *x*) with attributes *attr*, overwriting anything previously on the display.

`window.addstr(str[, attr])`

`window.addstr(y, x, str[, attr])`

Paint the character string *str* at (*y*, *x*) with attributes *attr*, overwriting anything previously on the display.

### Note

- Writing outside the window, subwindow, or pad raises `curses.error`. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the string is printed.
- A [bug in ncurses](https://bugs.python.org/issue35924) [https://bugs.python.org/issue35924], the backend for this Python module, can cause SegFaults when resizing windows. This is fixed in ncurses-6.1-20190511. If you are stuck with an earlier ncurses, you can avoid triggering this if you do not call `addstr()` with a *str* that has embedded newlines. Instead, call `addstr()` separately for each line.

`window.attroff(attr)`

Remove attribute *attr* from the “background” set applied to all writes to the current window.

`window.attron(attr)`

Add attribute *attr* from the “background” set applied to all writes to the current window.

`window.attrset(attr)`

Set the “background” set of attributes to *attr*. This set is initially 0 (no attributes).

`window.bkgd(ch[, attr])`

Set the background property of the window to the character

*ch*, with attributes *attr*. The change is then applied to every character position in that window:

- The attribute of every character in the window is changed to the new background attribute.
- Wherever the former background character appears, it is changed to the new background character.

`window.bkgdset(ch[, attr])`

Set the window's background. A window's background consists of a character and any combination of attributes. The attribute part of the background is combined (OR'ed) with all non-blank characters that are written into the window. Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations.

`window.border([ls[, rs[, ts[, bs[, tl[, tr[, bl[, br]]]]]]]]])`

Draw a border around the edges of the window. Each parameter specifies the character to use for a specific part of the border; see the table below for more details.

### Note

A 0 value for any parameter will cause the default character to be used for that parameter. Keyword parameters can *not* be used. The defaults are listed in this table:

| Default             | Value               |
|---------------------|---------------------|
| Left side           | <code>LINE</code>   |
| Right side          | <code>LINE</code>   |
| Top                 | <code>HLINE</code>  |
| Bottom              | <code>HLINE</code>  |
| Upper-left corner   | <code>CORNER</code> |
| Upper-right corner  | <code>CORNER</code> |
| Bottom-left corner  | <code>CORNER</code> |
| Bottom-right corner | <code>CORNER</code> |

`window.box([vertch, horch])`

Similar to `border()`, but both *ls* and *rs* are *vertch* and both *ts* and *bs* are *horch*. The default corner characters are always used by this function.

`window.chgat(attr)`

`window.chgat(num, attr)`

`window.chgat(y, x, attr)`

`window.chgat(y, x, num, attr)`

Set the attributes of *num* characters at the current cursor position, or at position (*y*, *x*) if supplied. If *num* is not given or is `-1`, the attribute will be set on all the characters to the end of the line. This function moves cursor to position (*y*, *x*) if supplied. The changed line will be touched using the `touchline()` method so that the contents will be redisplayed by the next window refresh.

`window.clear()`

Like `erase()`, but also cause the whole window to be repainted upon next call to `refresh()`.

`window.clearok(flag)`

If *flag* is `True`, the next call to `refresh()` will clear the window completely.

`window.clrtoeol()`

Erase from cursor to the end of the window: all lines below the cursor are deleted, and then the equivalent of `clrtoeol()` is performed.

`window.clrtoeol()`

Erase from cursor to the end of the line.

`window.cursyncup()`

Update the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

`window.delch([y, x])`

Delete any character at  $(y, x)$ .

`window.deleteln()`

Delete the line under the cursor. All following lines are moved up by one line.

`window.derwin(begin_y, begin_x)`

`window.derwin(nlines, ncols, begin_y, begin_x)`

An abbreviation for “derive window”, `derwin()` is the same as calling `subwin()`, except that `begin_y` and `begin_x` are relative to the origin of the window, rather than relative to the entire screen. Return a window object for the derived window.

`window.echochar(ch[, attr])`

Add character `ch` with attribute `attr`, and immediately call `refresh()` on the window.

`window.enclose(y, x)`

Test whether the given pair of screen-relative character-cell coordinates are enclosed by the given window, returning `True` or `False`. It is useful for determining what subset of the screen windows enclose the location of a mouse event.

*Changed in version 3.10:* Previously it returned `1` or `0` instead of `True` or `False`.

`window.encoding`

Encoding used to encode method arguments (Unicode strings and characters). The encoding attribute is inherited from the parent window when a subwindow is created, for example with `window.subwin()`. By default, current locale encoding is used (see `locale.getencoding()`).

*New in version 3.3.*

`window.erase()`

Clear the window.

`window.getbegyx()`

Return a tuple  $(y, x)$  of co-ordinates of upper-left corner.

`window.getbkgd()`

Return the given window's current background character/attribute pair.

`window.getch([y, x])`

Get a character. Note that the integer returned does *not* have to be in ASCII range: function keys, keypad keys and so on are represented by numbers higher than 255. In no-delay mode, return `-1` if there is no input, otherwise wait until a key is pressed.

`window.get_wch([y, x])`

Get a wide character. Return a character for most keys, or an integer for function keys, keypad keys, and other special keys. In no-delay mode, raise an exception if there is no input.

*New in version 3.3.*

`window.getkey([y, x])`

Get a character, returning a string instead of an integer, as `getch()` does. Function keys, keypad keys and other special keys return a multibyte string containing the key name. In no-delay mode, raise an exception if there is no input.

`window.getmaxyx()`

Return a tuple  $(y, x)$  of the height and width of the window.

`window.getparyx()`

Return the beginning coordinates of this window relative to its parent window as a tuple `(y, x)`. Return `(-1, -1)` if this window has no parent.

`window.getstr()`

`window.getstr(n)`

`window.getstr(y, x)`

`window.getstr(y, x, n)`

Read a bytes object from the user, with primitive line editing capacity.

`window.getyx()`

Return a tuple `(y, x)` of current cursor position relative to the window's upper-left corner.

`window.hline(ch, n)`

`window.hline(y, x, ch, n)`

Display a horizontal line starting at `(y, x)` with length `n` consisting of the character `ch`.

`window.idcok(flag)`

If `flag` is `False`, `curses` no longer considers using the hardware insert/delete character feature of the terminal; if `flag` is `True`, use of character insertion and deletion is enabled. When `curses` is first initialized, use of character insert/delete is enabled by default.

`window.idlok(flag)`

If `flag` is `True`, `curses` will try and use hardware line editing facilities. Otherwise, line insertion/deletion are disabled.

`window.immedok(flag)`

If `flag` is `True`, any change in the window image

automatically causes the window to be refreshed; you no longer have to call `refresh()` yourself. However, it may degrade performance considerably, due to repeated calls to `wrefresh`. This option is disabled by default.

`window.inch([y, x])`

Return the character at the given position in the window. The bottom 8 bits are the character proper, and upper bits are the attributes.

`window.insch(ch[, attr])`

`window.insch(y, x, ch[, attr])`

Paint character *ch* at (*y*, *x*) with attributes *attr*, moving the line from position *x* right by one character.

`window.insdelln(nlines)`

Insert *nlines* lines into the specified window above the current line. The *nlines* bottom lines are lost. For negative *nlines*, delete *nlines* lines starting with the one under the cursor, and move the remaining lines up. The bottom *nlines* lines are cleared. The current cursor position remains the same.

`window.insertln()`

Insert a blank line under the cursor. All following lines are moved down by one line.

`window.insnstr(str, n[, attr])`

`window.insnstr(y, x, str, n[, attr])`

Insert a character string (as many characters as will fit on the line) before the character under the cursor, up to *n* characters. If *n* is zero or negative, the entire string is inserted. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

`window.insstr(str[, attr])`

`window.insstr(y, x, str[, attr])`

Insert a character string (as many characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

`window.instr([n])`

`window.instr(y, x[, n])`

Return a bytes object of characters, extracted from the window starting at the current cursor position, or at *y*, *x* if specified. Attributes are stripped from the characters. If *n* is specified, `instr()` returns a string at most *n* characters long (exclusive of the trailing NUL).

`window.is_linetouched(line)`

Return `True` if the specified line was modified since the last call to `refresh()`; otherwise return `False`. Raise a `curses.error` exception if *line* is not valid for the given window.

`window.is_wintouched()`

Return `True` if the specified window was modified since the last call to `refresh()`; otherwise return `False`.

`window.keypad(flag)`

If *flag* is `True`, escape sequences generated by some keys (keypad, function keys) will be interpreted by `curses`. If *flag* is `False`, escape sequences will be left as is in the input stream.

`window.leaveok(flag)`

If *flag* is `True`, cursor is left where it is on update, instead of being at “cursor position.” This reduces cursor movement where possible. If possible the cursor will be made invisible.

If *flag* is `False`, cursor will always be at “cursor position” after an update.

`window.move(new_y, new_x)`

Move cursor to `(new_y, new_x)`.

`window.mvderwin(y, x)`

Move the window inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

`window.mvwin(new_y, new_x)`

Move the window so its upper-left corner is at `(new_y, new_x)`.

`window.nodelay(flag)`

If *flag* is `True`, `getch()` will be non-blocking.

`window.notimeout(flag)`

If *flag* is `True`, escape sequences will not be timed out.

If *flag* is `False`, after a few milliseconds, an escape sequence will not be interpreted, and will be left in the input stream as is.

`window.noutrefresh()`

Mark for refresh but wait. This function updates the data structure representing the desired state of the window, but does not force an update of the physical screen. To accomplish that, call `doupdate()`.

`window.overlay(destwin[, sminrow, smincol, dminrow, dmincol, dmaxrow, dmaxcol])`

Overlay the window on top of *destwin*. The windows need not be the same size, only the overlapping region is copied. This

copy is non-destructive, which means that the current background character does not overwrite the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of `overlay()` can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, and the other variables mark a rectangle in the destination window.

```
window.overwrite(destwin[, sminrow, smincol, dminrow, dmincol,  
dmaxrow, dmaxcol])
```

Overwrite the window on top of *destwin*. The windows need not be the same size, in which case only the overlapping region is copied. This copy is destructive, which means that the current background character overwrites the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of `overwrite()` can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, the other variables mark a rectangle in the destination window.

```
window.putwin(file)
```

Write all data associated with the window into the provided file object. This information can be later retrieved using the `getwin()` function.

```
window.redrawln(beg, num)
```

Indicate that the *num* screen lines, starting at line *beg*, are corrupted and should be completely redrawn on the next `refresh()` call.

```
window.redrawwin()
```

Touch the entire window, causing it to be completely redrawn on the next `refresh()` call.

```
window.refresh([pminrow, pmincol, sminrow, smincol, smaxrow,
```

*smaxcol*])

Update the display immediately (sync actual screen with previous drawing/deleting methods).

The 6 optional arguments can only be specified when the window is a pad created with `newpad()`. The additional parameters are needed to indicate what part of the pad and screen are involved. *pminrow* and *pmincol* specify the upper left-hand corner of the rectangle to be displayed in the pad. *sminrow*, *smincol*, *smaxrow*, and *smaxcol* specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of *pminrow*, *pmincol*, *sminrow*, or *smincol* are treated as if they were zero.

`window.resize(nlines, ncols)`

Reallocate storage for a curses window to adjust its dimensions to the specified values. If either dimension is larger than the current values, the window's data is filled with blanks that have the current background rendition (as set by `bkgdset()`) merged into them.

`window.scroll([lines = 1])`

Scroll the screen or scrolling region upward by *lines* lines.

`window.scrlok(flag)`

Control what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If *flag* is `False`, the cursor is left on the bottom line. If *flag* is `True`, the window is scrolled up one line. Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call `idlok()`.

`window.setscrreg(top, bottom)`

Set the scrolling region from line *top* to line *bottom*. All scrolling actions will take place in this region.

`window.standend()`

Turn off the standout attribute. On some terminals this has the side effect of turning off all attributes.

`window.standout()`

Turn on attribute *A\_STANDOUT*.

`window.subpad(begin_y, begin_x)`

`window.subpad(nlines, ncols, begin_y, begin_x)`

Return a sub-window, whose upper-left corner is at (*begin\_y*, *begin\_x*), and whose width/height is *ncols*/*nlines*.

`window.subwin(begin_y, begin_x)`

`window.subwin(nlines, ncols, begin_y, begin_x)`

Return a sub-window, whose upper-left corner is at (*begin\_y*, *begin\_x*), and whose width/height is *ncols*/*nlines*.

By default, the sub-window will extend from the specified position to the lower right corner of the window.

`window.syncdown()`

Touch each location in the window that has been touched in any of its ancestor windows. This routine is called by [refresh\(\)](#), so it should almost never be necessary to call it manually.

`window.syncok(flag)`

If *flag* is `True`, then [syncup\(\)](#) is called automatically whenever there is a change in the window.

`window.syncup()`

Touch all locations in ancestors of the window that have been changed in the window.

`window.timeout(delay)`

Set blocking or non-blocking read behavior for the window. If *delay* is negative, blocking read is used (which will wait indefinitely for input). If *delay* is zero, then non-blocking read is used, and `getch()` will return `-1` if no input is waiting. If *delay* is positive, then `getch()` will block for *delay* milliseconds, and return `-1` if there is still no input at the end of that time.

`window.touchline(start, count[, changed])`

Pretend *count* lines have been changed, starting with line *start*. If *changed* is supplied, it specifies whether the affected lines are marked as having been changed (*changed*=`True`) or unchanged (*changed*=`False`).

`window.touchwin()`

Pretend the whole window has been changed, for purposes of drawing optimizations.

`window.untouchwin()`

Mark all lines in the window as unchanged since the last call to `refresh()`.

`window.vline(ch, n[, attr])`

`window.vline(y, x, ch, n[, attr])`

Display a vertical line starting at (*y*, *x*) with length *n* consisting of the character *ch* with attributes *attr*.

## Constants

The `curses` module defines the following data members:

|                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <del>Dim</del> <del>set</del> <del>Ad</del> <del>DIM</del>                                                                                        |

New in version 3.7: A\_ITALIC was added.

Several constants are available to extract corresponding attributes returned by some methods.

### Meaning

|                                                                                                       |
|-------------------------------------------------------------------------------------------------------|
| <del>Bit</del> <del>mask</del> <del>_A</del> <del>ATTRIBUTES</del> <del>Attributes</del>              |
| <del>Bit</del> <del>mask</del> <del>_A</del> <del>CHARACTER</del> <del>character</del>                |
| <del>Bit</del> <del>mask</del> <del>_A</del> <del>COLOR</del> <del>color-pair field information</del> |

Keys are referred to by integer constants with names starting with KEY\_. The exact keycaps available are system dependent.

### Key constant

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| <del>Min</del> <del>us</del> <del>KEY</del> <del>_A</del> <del>Value</del>                                   |
| <del>Break</del> <del>set</del> <del>KEY</del> <del>(BREAK)</del>                                            |
| <del>Down</del> <del>set</del> <del>KEY</del> <del>DOWN</del>                                                |

| Terminal | KEY_SIZE  |
|----------|-----------|
| Maximum  | KEY_Value |

On VT100s and their software emulations, such as X terminal emulators, there are normally at least four function keys (**KEY\_F1**, **KEY\_F2**, **KEY\_F3**, **KEY\_F4**) available, and the arrow keys mapped to **KEY\_UP**, **KEY\_DOWN**, **KEY\_LEFT** and **KEY\_RIGHT** in the obvious way. If your machine has a PC keyboard, it is safe to expect arrow keys and twelve function keys (older PC keyboards may have only ten function keys); also, the following keypad mappings are standard:

| Constant  |
|-----------|
| KEY_IC    |
| KEY_DL    |
| KEY_HOME  |
| KEY_END   |
| KEY_PPAGE |
| KEY_NPAGE |

The following table lists characters from the alternate character set. These are inherited from the VT100 terminal, and will generally be available on software emulations such as X terminals. When there is no graphic available, curses falls back on a crude printable ASCII approximation.

### Note

These are available only after **initscr()** has been called.

The following table lists mouse button constants used by `getmouse()`:

| Meaning                           | button constant      |
|-----------------------------------|----------------------|
| <code>Mouse.BUTTON_PRESSED</code> | <code>M_PRESS</code> |

|                                                    |
|----------------------------------------------------|
| <del>Mouse.BUTTON_RELEASED</del>                   |
| <del>Mouse.BUTTON_CLICKED</del>                    |
| <del>Mouse.BUTTON_DOUBLE_CLICKED</del>             |
| <del>Mouse.BUTTON_TRIPLE_CLICKED</del>             |
| <del>Shift.BUTTON_SHIFT</del> button state change  |
| <del>Cursor.BUTTON_CLICK</del> button state change |
| <del>Cursor.BUTTON_HOLD</del> button state change  |

*Changed in version 3.10:* The `BUTTON5_*` constants are now exposed if they are provided by the underlying curses library.

The following table lists the predefined colors:

| Constant                                             |
|------------------------------------------------------|
| <del>Black</del> .COLOR_BLACK                        |
| <del>Blue</del> .COLOR_BLUE                          |
| <del>Cyan</del> (light green) <del>Cyan</del> (blue) |
| <del>Green</del> .COLOR_GREEN                        |
| <del>Magenta</del> .COLOR_MAGENTA                    |
| <del>Red</del> .COLOR_RED                            |
| <del>White</del> .COLOR_WHITE                        |
| <del>Yellow</del> .COLOR_YELLOW                      |

## **curses.textpad** — Text input widget for curses programs

The **curses.textpad** module provides a **Textbox** class that handles elementary text editing in a curses window, supporting a set of keybindings resembling those of Emacs (thus, also of Netscape Navigator, BEdit 6.x, FrameMaker, and many other programs). The module also provides a rectangle-drawing function useful for framing text boxes or for other purposes.

The module **curses.textpad** defines the following function:

`curses.textpad.rectangle(win, uly, ulx, lry, lrx)`

Draw a rectangle. The first argument must be a window object; the remaining arguments are coordinates relative to that window. The second and third arguments are the y and x coordinates of the upper left hand corner of the rectangle to be drawn; the fourth and fifth arguments are the y and x coordinates of the lower right hand corner. The rectangle will be drawn using VT100/IBM PC forms characters on terminals that make this possible (including xterm and most other software terminal emulators). Otherwise it will be drawn with ASCII dashes, vertical bars, and plus signs.

## Textbox objects

You can instantiate a **Textbox** object as follows:

```
class curses.textpad.Textbox(win)
```

Return a textbox widget object. The *win* argument should be a curses **window** object in which the textbox is to be contained. The edit cursor of the textbox is initially located at the upper left hand corner of the containing window, with coordinates (0, 0). The instance's **stripspaces** flag is initially on.

**Textbox** objects have the following methods:

```
edit([validator])
```

This is the entry point you will normally use. It accepts editing keystrokes until one of the termination keystrokes is entered. If *validator* is supplied, it must be a function. It will be called for each keystroke entered with the keystroke as a parameter; command dispatch is done on the result. This method returns the window contents as a string; whether blanks in the window are included is affected by the **stripspaces** attribute.

```
do_command(ch)
```

Process a single command keystroke. Here are the supported special keystrokes:

### Keystroke

---

Go to left edge of window.

---

Cursor left, wrapping to previous line if appropriate.

---

Delete character under cursor.

---

Go to right edge (stripspaces off) or end of line (stripspaces on).

---

Cursor right, wrapping to next line when appropriate.

---

Terminate, returning the window contents.

---

Delete character backward.

---

Terminate if the window is 1 line, otherwise insert newline.

---

If line is blank, delete it, otherwise clear to end of line.

---

Refresh screen.

---

Cursor down; move down one line.

---

Insert a blank line at cursor location.

---

Cursor up; move up one line.

---

Move operations do nothing if the cursor is at an edge where the movement is not possible. The following synonyms are supported where possible:

### Keystroke

---

**KEY\_LEFTB**

---

**KEY\_RIGHT**

---

**KEY\_VB1-P**

---

**KEY\_DOWNN**

---

**KEY\_BACKSPACE**

---

All other keystrokes are treated as a command to insert the given character and move right (with line wrapping).

gather()

Return the window contents as a string; whether blanks in the window are included is affected by the **stripspaces** member.

stripspaces

This attribute is a flag which controls the interpretation of blanks in the window. When it is on, trailing blanks on each line are ignored; any cursor motion that would land the cursor on a trailing blank goes to the end of that line instead, and trailing blanks are stripped when the window contents are gathered.

# curses.ascii — Utilities for ASCII characters

Source code: [Lib/curses/ascii.py](https://github.com/python/cpython/tree/3.11/Lib/curses/ascii.py) [https://github.com/python/cpython/tree/3.11/Lib/curses/ascii.py]

The `curses.ascii` module supplies name constants for ASCII characters and functions to test membership in various ASCII character classes. The constants supplied are names for control characters as follows:

## Meaning

`curses.ascii.NUL`

Start of line `SOH`, console interrupt

Start of text `STX`

End of text `ETX`

End of a transmission

Empirical goes with `ACK` flow control

Acknowledged `ACK`

`curses.ascii.BEL`

`curses.ascii.BS`

`curses.ascii.TAB`

Alias for `ASCII` “Horizontal tab”

`curses.ascii.LF`

Alias for `ASCII` “New line”

`curses.ascii.VT`

`curses.ascii.FF`

`curses.ascii.CR`

Shift out `SO` on alternate character set

Shift in `SI` on default character set

`curses.ascii.DLE`

`curses.ascii.DC` control

`curses.ascii.DC2`, block-mode flow control

`curses.ascii.DC3` control

|                                                       |
|-------------------------------------------------------|
| <del>Device ascii.DC4</del>                           |
| <del>Negative ascii.NAK</del>                         |
| <del>Synchronous SYE</del>                            |
| <del>End of transmit EOT block</del>                  |
| <del>Cancel ascii.CAN</del>                           |
| <del>End of ascii.EOM</del>                           |
| <del>Substitute ii.SUB</del>                          |
| <del>Escape ascii.ESC</del>                           |
| <del>File separator FS</del>                          |
| <del>Group separator GS</del>                         |
| <del>Record separator RS, block-mode terminator</del> |
| <del>Unit separator US</del>                          |
| <del>Space ascii.SP</del>                             |
| <del>Delete ascii.DEL</del>                           |

Note that many of these have little practical significance in modern usage. The mnemonics derive from teleprinter conventions that predate digital computers.

The module supplies the following functions, patterned on those in the standard C library:

`curses.ascii.isalnum(c)`

Checks for an ASCII alphanumeric character; it is equivalent to `isalpha(c)` or `isdigit(c)`.

`curses.ascii.isalpha(c)`

Checks for an ASCII alphabetic character; it is equivalent to `isupper(c)` or `islower(c)`.

`curses.ascii.isascii(c)`

Checks for a character value that fits in the 7-bit ASCII set.

`curses.ascii.isblank(c)`

Checks for an ASCII whitespace character; space or horizontal tab.

`curses.ascii.iscntrl(c)`

Checks for an ASCII control character (in the range 0x00 to 0x1f or 0x7f).

`curses.ascii.isdigit(c)`

Checks for an ASCII decimal digit, '0' through '9'. This is equivalent to `c` in `string.digits`.

`curses.ascii.isgraph(c)`

Checks for ASCII any printable character except space.

`curses.ascii.islower(c)`

Checks for an ASCII lower-case character.

`curses.ascii.isprint(c)`

Checks for any ASCII printable character including space.

`curses.ascii.ispunct(c)`

Checks for any printable ASCII character which is not a space or an alphanumeric character.

`curses.ascii.isspace(c)`

Checks for ASCII white-space characters; space, line feed, carriage return, form feed, horizontal tab, vertical tab.

`curses.ascii.isupper(c)`

Checks for an ASCII uppercase letter.

`curses.ascii.isxdigit(c)`

Checks for an ASCII hexadecimal digit. This is equivalent to `c` in `string.hexdigits`.

`curses.ascii.isctrl(c)`

Checks for an ASCII control character (ordinal values 0 to 31).

`curses.ascii.ismeta(c)`

Checks for a non-ASCII character (ordinal values 0x80 and above).

These functions accept either integers or single-character strings; when the argument is a string, it is first converted using the built-in function `ord()`.

Note that all these functions check ordinal bit values derived from the character of the string you pass in; they do not actually know anything about the host machine's character encoding.

The following two functions take either a single-character string or integer byte value; they return a value of the same type.

`curses.ascii.ascii(c)`

Return the ASCII value corresponding to the low 7 bits of `c`.

`curses.ascii.ctrl(c)`

Return the control character corresponding to the given character (the character bit value is bitwise-anded with 0x1f).

`curses.ascii.alt(c)`

Return the 8-bit character corresponding to the given ASCII character (the character bit value is bitwise-ored with 0x80).

The following function takes either a single-character string or integer value; it returns a string.

`curses.ascii.unctrl(c)`

Return a string representation of the ASCII character `c`. If `c` is printable, this string is the character itself. If the character is a control character (0x00–0x1f) the string consists of a caret ('^') followed by the corresponding uppercase letter. If the character is an ASCII delete (0x7f) the string is '^?'. If the character has its meta bit (0x80) set, the meta bit is stripped, the preceding rules applied, and '!' prepended to the result.

`curses.ascii.controlnames`

A 33-element string array that contains the ASCII mnemonics for the thirty-two ASCII control characters from 0 (NUL) to 0x1f (US), in order, plus the mnemonic `SP` for the space character.

# `curses.panel` — A panel stack extension for `curses`

---

Panels are windows with the added feature of depth, so they can be stacked on top of each other, and only the visible portions of each window will be displayed. Panels can be added, moved up or down in the stack, and removed.

## Functions

The module `curses.panel` defines the following functions:

`curses.panel.bottom_panel()`

Returns the bottom panel in the panel stack.

`curses.panel.new_panel(win)`

Returns a panel object, associating it with the given window *win*. Be aware that you need to keep the returned panel object referenced explicitly. If you don't, the panel object is garbage collected and removed from the panel stack.

`curses.panel.top_panel()`

Returns the top panel in the panel stack.

`curses.panel.update_panels()`

Updates the virtual screen after changes in the panel stack. This does not call `curses.doupdate()`, so you'll have to do this yourself.

## Panel Objects

Panel objects, as returned by `new_panel()` above, are windows with a stacking order. There's always a window associated with a panel which determines the content, while the panel methods are responsible for the window's depth in the panel stack.

Panel objects have the following methods:

`Panel.above()`

Returns the panel above the current panel.

`Panel.below()`

Returns the panel below the current panel.

`Panel.bottom()`

Push the panel to the bottom of the stack.

`Panel.hidden()`

Returns `True` if the panel is hidden (not visible), `False` otherwise.

`Panel.hide()`

Hide the panel. This does not delete the object, it just makes the window on screen invisible.

`Panel.move(y, x)`

Move the panel to the screen coordinates `(y, x)`.

`Panel.replace(win)`

Change the window associated with the panel to the window `win`.

`Panel.set_userptr(obj)`

Set the panel's user pointer to `obj`. This is used to associate an arbitrary piece of data with the panel, and can be any Python object.

`Panel.show()`

Display the panel (which might have been hidden).

`Panel.top()`

Push panel to the top of the stack.

`Panel.userptr()`

Returns the user pointer for the panel. This might be any Python object.

`Panel.window()`

Returns the window object associated with the panel.

# platform — Access to underlying platform's identifying data

**Source code:** [Lib/platform.py](https://github.com/python/cpython/tree/3.11/Lib/platform.py) [https://github.com/python/cpython/tree/3.11/Lib/platform.py]

---

## Note

Specific platforms listed alphabetically, with Linux included in the Unix section.

## Cross Platform

`platform.architecture(executable=sys.executable, bits="", linkage="")`

Queries the given executable (defaults to the Python interpreter binary) for various architecture information.

Returns a tuple (`bits`, `linkage`) which contain information about the bit architecture and the linkage format used for the executable. Both values are returned as strings.

Values that cannot be determined are returned as given by the parameter presets. If `bits` is given as `' '`, the `sizeof(pointer)` (or `sizeof(long)` on Python version < 1.5.2) is used as indicator for the supported pointer size.

The function relies on the system's `file` command to do the actual work. This is available on most if not all Unix platforms and some non-Unix platforms and then only if the executable points to the Python interpreter. Reasonable defaults are used when the above needs are not met.

## Note

On macOS (and perhaps other platforms), executable files may be universal files containing multiple architectures.

To get at the “64-bitness” of the current interpreter, it is more reliable to query the `sys.maxsize` attribute:

```
is_64bits = sys.maxsize > 2**32
```

## `platform.machine()`

Returns the machine type, e.g. `'AMD64'`. An empty string is returned if the value cannot be determined.

## `platform.node()`

Returns the computer’s network name (may not be fully qualified!). An empty string is returned if the value cannot be determined.

## `platform.platform(aliased=0, terse=0)`

Returns a single string identifying the underlying platform with as much useful information as possible.

The output is intended to be *human readable* rather than machine parseable. It may look different on different platforms and this is intended.

If *aliased* is true, the function will use aliases for various platforms that report system names which differ from their common names, for example SunOS will be reported as Solaris. The `system_alias()` function is used to implement this.

Setting *terse* to true causes the function to return only the absolute minimum information needed to identify the platform.

*Changed in version 3.8:* On macOS, the function now uses

`mac_ver()`, if it returns a non-empty release string, to get the macOS version rather than the darwin version.

`platform.processor()`

Returns the (real) processor name, e.g. `'amd64'`.

An empty string is returned if the value cannot be determined. Note that many platforms do not provide this information or simply return the same value as for `machine()`. NetBSD does this.

`platform.python_build()`

Returns a tuple `(buildno, builddate)` stating the Python build number and date as strings.

`platform.python_compiler()`

Returns a string identifying the compiler used for compiling Python.

`platform.python_branch()`

Returns a string identifying the Python implementation SCM branch.

`platform.python_implementation()`

Returns a string identifying the Python implementation. Possible return values are: `'CPython'`, `'IronPython'`, `'Jython'`, `'PyPy'`.

`platform.python_revision()`

Returns a string identifying the Python implementation SCM revision.

`platform.python_version()`

Returns the Python version as string `'major.minor.patchlevel'`.

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to 0).

### `platform.python_version_tuple()`

Returns the Python version as tuple (major, minor, patchlevel) of strings.

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to '0').

### `platform.release()`

Returns the system's release, e.g. '2.2.0' or 'NT'. An empty string is returned if the value cannot be determined.

### `platform.system()`

Returns the system/OS name, such as 'Linux', 'Darwin', 'Java', 'Windows'. An empty string is returned if the value cannot be determined.

### `platform.system_alias(system, release, version)`

Returns (system, release, version) aliased to common marketing names used for some systems. It also does some reordering of the information in some cases where it would otherwise cause confusion.

### `platform.version()`

Returns the system's release version, e.g. '#3 on degas'. An empty string is returned if the value cannot be determined.

### `platform.uname()`

Fairly portable uname interface. Returns a `namedtuple()` containing six attributes: `system`, `node`, `release`, `version`, `machine`, and `processor`.

Note that this adds a sixth attribute (`processor`) not present in the `os.uname()` result. Also, the attribute names are

different for the first two attributes; `os.uname()` names them **sysname** and **nodename**.

Entries which cannot be determined are set to `' '`.

*Changed in version 3.3:* Result changed from a tuple to a `namedtuple()`.

## Java Platform

```
platform.java_ver(release="", vendor="", vminfo=("", "", ""), osinfo=("", ""))
```

Version interface for Jython.

Returns a tuple (release, vendor, vminfo, osinfo) with *vminfo* being a tuple (vm\_name, vm\_release, vm\_vendor) and *osinfo* being a tuple (os\_name, os\_version, os\_arch). Values which cannot be determined are set to the defaults given as parameters (which all default to `' '`).

## Windows Platform

```
platform.win32_ver(release="", version="", csd="", ptype="")
```

Get additional version information from the Windows Registry and return a tuple (release, version, csd, ptype) referring to OS release, version number, CSD level (service pack) and OS type (multi/single processor). Values which cannot be determined are set to the defaults given as parameters (which all default to an empty string).

As a hint: *ptype* is 'Uniprocessor Free' on single processor NT machines and 'Multiprocessor Free' on multi processor machines. The 'Free' refers to the OS version being free of debugging code. It could also state 'Checked' which means the OS version uses debugging code, i.e. code that checks arguments, ranges, etc.

`platform.win32_edition()`

Returns a string representing the current Windows edition, or `None` if the value cannot be determined. Possible values include but are not limited to `'Enterprise'`, `'IoTAP'`, `'ServerStandard'`, and `'nanoserver'`.

*New in version 3.8.*

`platform.win32_is_iot()`

Return `True` if the Windows edition returned by `win32_edition()` is recognized as an IoT edition.

*New in version 3.8.*

## macOS Platform

`platform.mac_ver(release="", versioninfo=("", "", ""), machine="")`

Get macOS version information and return it as tuple `(release, versioninfo, machine)` with `versioninfo` being a tuple `(version, dev_stage, non_release_version)`.

Entries which cannot be determined are set to `' '`. All tuple entries are strings.

## Unix Platforms

`platform.libc_ver(executable=sys.executable, lib="", version="", chunksize=16384)`

Tries to determine the libc version against which the file `executable` (defaults to the Python interpreter) is linked. Returns a tuple of strings `(lib, version)` which default to the given parameters in case the lookup fails.

Note that this function has intimate knowledge of how different libc versions add symbols to the executable is probably only usable for executables compiled using **gcc**.

The file is read and scanned in chunks of *chunksize* bytes.

## Linux Platforms

### `platform.freedesktop_os_release()`

Get operating system identification from `os-release` file and return it as a dict. The `os-release` file is a [freedesktop.org standard](https://www.freedesktop.org/software/systemd/man/os-release.html) [https://www.freedesktop.org/software/systemd/man/os-release.html] and is available in most Linux distributions. A noticeable exception is Android and Android-based distributions.

Raises **OSError** or subclass when neither `/etc/os-release` nor `/usr/lib/os-release` can be read.

On success, the function returns a dictionary where keys and values are strings. Values have their special characters like `"` and `$` unquoted. The fields `NAME`, `ID`, and `PRETTY_NAME` are always defined according to the standard. All other fields are optional. Vendors may include additional fields.

Note that fields like `NAME`, `VERSION`, and `VARIANT` are strings suitable for presentation to users. Programs should use fields like `ID`, `ID_LIKE`, `VERSION_ID`, or `VARIANT_ID` to identify Linux distributions.

Example:

```
def get_like_distro():
    info = platform.freedesktop_os_release()
    ids = [info["ID"]]
    if "ID_LIKE" in info:
        # ids are space separated and ordered by pr
        ids.extend(info["ID_LIKE"].split())
    return ids
```

*New in version 3.10.*

# errno — Standard errno system symbols

---

This module makes available standard `errno` system symbols. The value of each symbol is the corresponding integer value. The names and descriptions are borrowed from `linux/include/errno.h`, which should be all-inclusive.

`errno.errorcode`

Dictionary providing a mapping from the `errno` value to the string name in the underlying system. For instance, `errno.errorcode[errno.EPERM]` maps to `'EPERM'`.

To translate a numeric error code to an error message, use `os.strerror()`.

Of the following list, symbols that are not used on the current platform are not defined by the module. The specific list of defined symbols is available as `errno.errorcode.keys()`. Symbols available can include:

`errno.EPERM`

Operation not permitted. This error is mapped to the exception `PermissionError`.

`errno.ENOENT`

No such file or directory. This error is mapped to the exception `FileNotFoundError`.

`errno.ESRCH`

No such process. This error is mapped to the exception `ProcessLookupError`.

errno.EINTR

Interrupted system call. This error is mapped to the exception [\*\*InterruptedError\*\*](#).

errno.EIO

I/O error

errno.ENXIO

No such device or address

errno.E2BIG

Arg list too long

errno.ENOEXEC

Exec format error

errno.EBADF

Bad file number

errno.ECHILD

No child processes. This error is mapped to the exception [\*\*ChildProcessError\*\*](#).

errno.EAGAIN

Try again. This error is mapped to the exception [\*\*BlockingIOError\*\*](#).

errno.ENOMEM

Out of memory

errno.EACCES

Permission denied. This error is mapped to the exception [\*\*PermissionError\*\*](#).

errno.EFAULT

Bad address

errno.ENOTBLK

Block device required

errno.EBUSY

Device or resource busy

errno.EEXIST

File exists. This error is mapped to the exception

**FileExistsError.**

errno.EXDEV

Cross-device link

errno.ENODEV

No such device

errno.ENOTDIR

Not a directory. This error is mapped to the exception

**NotADirectoryError.**

errno.EISDIR

Is a directory. This error is mapped to the exception

**IsADirectoryError.**

errno.EINVAL

Invalid argument

errno.ENFILE

File table overflow

errno.EMFILE

Too many open files

errno.ENOTTY

Not a typewriter

errno.ETXTBSY

Text file busy

errno.EFBIG

File too large

errno.ENOSPC

No space left on device

errno.ESPIPE

Illegal seek

errno.EROFS

Read-only file system

errno.EMLINK

Too many links

errno.EPIPE

Broken pipe. This error is mapped to the exception **BrokenPipeError**.

errno.EDOM

Math argument out of domain of func

errno.ERANGE

Math result not representable

errno.EDEADLK

Resource deadlock would occur

errno.ENAMETOOLONG

File name too long

errno.ENOLCK

No record locks available

errno.ENOSYS

Function not implemented

errno.ENOTEMPTY

Directory not empty

errno.ELOOP

Too many symbolic links encountered

errno.EWOULDBLOCK

Operation would block. This error is mapped to the exception [BlockingIOError](#).

errno.ENOMSG

No message of desired type

errno.EIDRM

Identifier removed

errno.ECHRNG

Channel number out of range

errno.EL2NSYNC

Level 2 not synchronized

errno.EL3HLT

Level 3 halted

errno.EL3RST

Level 3 reset

errno.ELNRNG

Link number out of range

errno.EUNATCH

Protocol driver not attached

errno.ENOCSI

No CSI structure available

errno.EL2HLT

Level 2 halted

errno.EBADE

Invalid exchange

errno.EBADR

Invalid request descriptor

errno.EXFULL

Exchange full

errno.ENOANO

No anode

errno.EBADRQC

Invalid request code

errno.EBADSLT

Invalid slot

errno.EDEADLOCK

File locking deadlock error

errno.EBFONT

Bad font file format

errno.ENOSTR

Device not a stream

errno.ENODATA

No data available

errno.ETIME

Timer expired

errno.ENOSR

Out of streams resources

errno.ENONET

Machine is not on the network

errno.ENOPKG

Package not installed

errno.EREMOTE

Object is remote

errno.ENOLINK

Link has been severed

errno.EADV

Advertise error

errno.ESRMNT

Srmount error

errno.ECOMM

Communication error on send

errno.EPROTO

Protocol error

errno.EMULTIHOP

Multihop attempted

errno.EDOTDOT

RFS specific error

errno.EBADMSG

Not a data message

errno.EOVERFLOW

Value too large for defined data type

errno.ENOTUNIQ

Name not unique on network

errno.EBADFD

File descriptor in bad state

errno.EREMCHG

Remote address changed

errno.ELIBACC

Can not access a needed shared library

errno.ELIBBAD

Accessing a corrupted shared library

errno.ELIBSCN

.lib section in a.out corrupted

errno.ELIBMAX

Attempting to link in too many shared libraries

errno.ELIBEXEC

Cannot exec a shared library directly

errno.EILSEQ

Illegal byte sequence

errno.ERESTART

Interrupted system call should be restarted

errno.ESTRPIPE

Streams pipe error

errno.EUSERS

Too many users

errno.ENOTSOCK

Socket operation on non-socket

errno.EDESTADDRREQ

Destination address required

errno.EMSGSIZE

Message too long

errno.EPROTOTYPE

Protocol wrong type for socket

errno.ENOPROTOOPT

Protocol not available

errno.EPROTONOSUPPORT

Protocol not supported

errno.ESOCKTNOSUPPORT

Socket type not supported

errno.EOPNOTSUPP

Operation not supported on transport endpoint

errno.EPFNOSUPPORT

Protocol family not supported

errno.EAFNOSUPPORT

Address family not supported by protocol

errno.EADDRINUSE

Address already in use

errno.EADDRNOTAVAIL

Cannot assign requested address

errno.ENETDOWN

Network is down

errno.ENETUNREACH

Network is unreachable

errno.ENETRESET

Network dropped connection because of reset

errno.ECONNABORTED

Software caused connection abort. This error is mapped to the exception `ConnectionAbortedError`.

errno.ECONNRESET

Connection reset by peer. This error is mapped to the exception `ConnectionResetError`.

errno.ENOBUFS

No buffer space available

errno.EISCONN

Transport endpoint is already connected

errno.ENOTCONN

Transport endpoint is not connected

errno.ESHUTDOWN

Cannot send after transport endpoint shutdown. This error is mapped to the exception `BrokenPipeError`.

errno.ETOOMANYREFS

Too many references: cannot splice

errno.ETIMEDOUT

Connection timed out. This error is mapped to the exception **TimeoutError**.

errno.ECONNREFUSED

Connection refused. This error is mapped to the exception **ConnectionRefusedError**.

errno.EHOSTDOWN

Host is down

errno.EHOSTUNREACH

No route to host

errno.EALREADY

Operation already in progress. This error is mapped to the exception **BlockingIOError**.

errno.EINPROGRESS

Operation now in progress. This error is mapped to the exception **BlockingIOError**.

errno.ESTALE

Stale NFS file handle

errno.EUCLEAN

Structure needs cleaning

errno.ENOTNAM

Not a XENIX named type file

errno.ENAVAIL

No XENIX semaphores available

errno.EISNAM

Is a named type file

errno.EREMOTEIO

Remote I/O error

errno.EDQUOT

Quota exceeded

errno.EQFULL

Interface output queue is full

*New in version 3.11.*

errno.ENOTCAPABLE

Capabilities insufficient. This error is mapped to the exception [PermissionError](#).

[Availability](#): WASI, FreeBSD

*New in version 3.11.1.*

# ctypes — A foreign function library for Python

Source code: [Lib/ctypes](https://github.com/python/cpython/tree/3.11/Lib/ctypes) [https://github.com/python/cpython/tree/3.11/Lib/ctypes]

---

**ctypes** is a foreign function library for Python. It provides C compatible data types, and allows calling functions in DLLs or shared libraries. It can be used to wrap these libraries in pure Python.

## ctypes tutorial

Note: The code samples in this tutorial use **doctest** to make sure that they actually work. Since some code samples behave differently under Linux, Windows, or macOS, they contain doctest directives in comments.

Note: Some code samples reference the ctypes **c\_int** type. On platforms where `sizeof(long) == sizeof(int)` it is an alias to **c\_long**. So, you should not be confused if **c\_long** is printed if you would expect **c\_int** — they are actually the same type.

## Loading dynamic link libraries

**ctypes** exports the *cdll*, and on Windows *windll* and *oledll* objects, for loading dynamic link libraries.

You load libraries by accessing them as attributes of these objects. *cdll* loads libraries which export functions using the standard `cdecl` calling convention, while *windll* libraries call functions using the `stdcall` calling convention. *oledll* also uses the `stdcall` calling convention, and assumes the functions return a Windows **HRESULT** error code. The error code is used to automatically raise

an `OSError` exception when the function call fails.

*Changed in version 3.3:* Windows errors used to raise `WindowsError`, which is now an alias of `OSError`.

Here are some examples for Windows. Note that `msvcrt` is the MS standard C library containing most standard C functions, and uses the `cdecl` calling convention:

```
>>> from ctypes import *
>>> print(windll.kernel32)
<WinDLL 'kernel32', handle ... at ...>
>>> print(cdll.msvcrt)
<CDLL 'msvcrt', handle ... at ...>
>>> libc = cdll.msvcrt
>>>
```

Windows appends the usual `.dll` file suffix automatically.

### Note

Accessing the standard C library through `cdll.msvcrt` will use an outdated version of the library that may be incompatible with the one being used by Python. Where possible, use native Python functionality, or else import and use the `msvcrt` module.

On Linux, it is required to specify the filename *including* the extension to load a library, so attribute access can not be used to load libraries. Either the `LoadLibrary()` method of the `dll` loaders should be used, or you should load the library by creating an instance of `CDLL` by calling the constructor:

```
>>> cdll.LoadLibrary("libc.so.6")
<CDLL 'libc.so.6', handle ... at ...>
>>> libc = CDLL("libc.so.6")
>>> libc
<CDLL 'libc.so.6', handle ... at ...>
>>>
```

## Accessing functions from loaded dlls

Functions are accessed as attributes of dll objects:

```
>>> from ctypes import *
>>> libc.printf
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.GetModuleHandleA)
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.MyOwnFunction)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 239, in __getattr__
    func = _StdcallFuncPtr(name, self)
AttributeError: function 'MyOwnFunction' not found
>>>
```

Note that win32 system dlls like `kernel32` and `user32` often export ANSI as well as UNICODE versions of a function. The UNICODE version is exported with an `_w` appended to the name, while the ANSI version is exported with an `_A` appended to the name. The win32 `GetModuleHandle` function, which returns a *module handle* for a given module name, has the following C prototype, and a macro is used to expose one of them as `GetModuleHandle` depending on whether UNICODE is defined or not:

```
/* ANSI version */
HMODULE GetModuleHandleA(LPCSTR lpModuleName);
/* UNICODE version */
HMODULE GetModuleHandleW(LPCWSTR lpModuleName);
```

*windll* does not try to select one of them by magic, you must access the version you need by specifying `GetModuleHandleA` or `GetModuleHandleW` explicitly, and then call it with bytes or string objects respectively.

Sometimes, dlls export functions with names which aren't valid Python identifiers, like `"??2@YAPAXI@Z"`. In this case you have to use `getattr()` to retrieve the function:

```
>>> getattr(cdll.msvcrt, "??2@YAPAXI@Z")
```

```
<_FuncPtr object at 0x...>
>>>
```

On Windows, some dlls export functions not by name but by ordinal. These functions can be accessed by indexing the dll object with the ordinal number:

```
>>> cdll.kernel32[1]
<_FuncPtr object at 0x...>
>>> cdll.kernel32[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 310, in __getitem__
    func = _StdcallFuncPtr(name, self)
AttributeError: function ordinal 0 not found
>>>
```

## Calling functions

You can call these functions like any other Python callable. This example uses the `time()` function, which returns system time in seconds since the Unix epoch, and the `GetModuleHandleA()` function, which returns a win32 module handle.

This example calls both functions with a `NULL` pointer (`None` should be used as the `NULL` pointer):

```
>>> print(libc.time(None))
1150640792
>>> print(hex(windll.kernel32.GetModuleHandleA(None)))
0x1d000000
>>>
```

**ValueError** is raised when you call an `stdcall` function with the `cdecl` calling convention, or vice versa:

```
>>> cdll.kernel32.GetModuleHandleA(None)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with not enough arguments
```

```
>>>
```

```
>>> windll.msvcrt.printf(b"spam")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with too many arguments
>>>
```

To find out the correct calling convention you have to look into the C header file or the documentation for the function you want to call.

On Windows, **ctypes** uses win32 structured exception handling to prevent crashes from general protection faults when functions are called with invalid argument values:

```
>>> windll.kernel32.GetModuleHandleA(32)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
OSError: exception: access violation reading 0x00000020
>>>
```

There are, however, enough ways to crash Python with **ctypes**, so you should be careful anyway. The **faulthandler** module can be helpful in debugging crashes (e.g. from segmentation faults produced by erroneous C library calls).

None, integers, bytes objects and (unicode) strings are the only native Python objects that can directly be used as parameters in these function calls. None is passed as a C NULL pointer, bytes objects and strings are passed as pointer to the memory block that contains their data (char\* or wchar\_t\*). Python integers are passed as the platforms default C int type, their value is masked to fit into the C type.

Before we move on calling functions with other parameter types, we have to learn more about **ctypes** data types.

## Fundamental data types

**ctypes** defines a number of primitive C compatible data types:

| Python type                           | C type                                |
|---------------------------------------|---------------------------------------|
| <code>bool(1)</code>                  | <code>_Bool</code>                    |
| <code>character bytes object</code>   | <code>char</code>                     |
| <code>wcharacter string</code>        | <code>wchar_t</code>                  |
| <code>char</code>                     | <code>char</code>                     |

| <code>None</code>                     | <code>None</code>                     |

1. The constructor accepts any object with a truth value.

All these types can be created by calling them with an optional initializer of the correct type and value:

```
>>> c_int()
c_long(0)
>>> c_wchar_p("Hello, World")
c_wchar_p(140018365411392)
>>> c_ushort(-3)
c_ushort(65533)
>>>
```

Since these types are mutable, their value can also be changed afterwards:

```

>>> i = c_int(42)
>>> print(i)
c_long(42)
>>> print(i.value)
42
>>> i.value = -99
>>> print(i.value)
-99
>>>

```

Assigning a new value to instances of the pointer types `c_char_p`, `c_wchar_p`, and `c_void_p` changes the *memory location* they point to, *not the contents* of the memory block (of course not, because Python bytes objects are immutable):

```

>>> s = "Hello, World"
>>> c_s = c_wchar_p(s)
>>> print(c_s)
c_wchar_p(139966785747344)
>>> print(c_s.value)
Hello World
>>> c_s.value = "Hi, there"
>>> print(c_s) # the memory location has changed
c_wchar_p(139966783348904)
>>> print(c_s.value)
Hi, there
>>> print(s) # first object is unchanged
Hello, World
>>>

```

You should be careful, however, not to pass them to functions expecting pointers to mutable memory. If you need mutable memory blocks, ctypes has a `create_string_buffer()` function which creates these in various ways. The current memory block contents can be accessed (or changed) with the `raw` property; if you want to access it as NUL terminated string, use the `value` property:

```

>>> from ctypes import *
>>> p = create_string_buffer(3) # create a 3

```

```

>>> print(sizeof(p), repr(p.raw))
3 b'\x00\x00\x00'
>>> p = create_string_buffer(b"Hello")          # create a buffer
>>> print(sizeof(p), repr(p.raw))
6 b'Hello\x00'
>>> print(repr(p.value))
b'Hello'
>>> p = create_string_buffer(b"Hello", 10) # create a 10-byte buffer
>>> print(sizeof(p), repr(p.raw))
10 b'Hello\x00\x00\x00\x00\x00'
>>> p.value = b"Hi"
>>> print(sizeof(p), repr(p.raw))
10 b'Hi\x00lo\x00\x00\x00\x00'
>>>

```

The `create_string_buffer()` function replaces the old `c_buffer()` function (which is still available as an alias). To create a mutable memory block containing unicode characters of the C type `wchar_t`, use the `create_unicode_buffer()` function.

## Calling functions, continued

Note that `printf` prints to the real standard output channel, *not* to `sys.stdout`, so these examples will only work at the console prompt, not from within *IDLE* or *PythonWin*:

```

>>> printf = libc.printf
>>> printf(b"Hello, %s\n", b"World!")
Hello, World!
14
>>> printf(b"Hello, %S\n", "World!")
Hello, World!
14
>>> printf(b"%d bottles of beer\n", 42)
42 bottles of beer
19
>>> printf(b"%f bottles of beer\n", 42.5)
Traceback (most recent call last):

```

```
File "<stdin>", line 1, in <module>
ArgumentError: argument 2: TypeError: Don't know how to
>>>
```

As has been mentioned before, all Python types except integers, strings, and bytes objects have to be wrapped in their corresponding **ctypes** type, so that they can be converted to the required C data type:

```
>>> printf(b"An int %d, a double %f\n", 1234, c_double(3.14))
An int 1234, a double 3.140000
31
>>>
```

## Calling variadic functions

On a lot of platforms calling variadic functions through ctypes is exactly the same as calling functions with a fixed number of parameters. On some platforms, and in particular ARM64 for Apple Platforms, the calling convention for variadic functions is different than that for regular functions.

On those platforms it is required to specify the *argtypes* attribute for the regular, non-variadic, function arguments:

```
libc.printf.argtypes = [ctypes.c_char_p]
```

Because specifying the attribute does not inhibit portability it is advised to always specify *argtypes* for all variadic functions.

## Calling functions with your own custom data types

You can also customize **ctypes** argument conversion to allow instances of your own classes be used as function arguments. **ctypes** looks for an **`__as_parameter__`** attribute and uses this as the function argument. Of course, it must be one of integer, string, or bytes:

```
>>> class Bottles:
...     def __init__(self, number):
```

```

...         self._as_parameter_ = number
...
>>> bottles = Bottles(42)
>>> printf(b"%d bottles of beer\n", bottles)
42 bottles of beer
19
>>>

```

If you don't want to store the instance's data in the `_as_parameter_` instance variable, you could define a [property](#) which makes the attribute available on request.

## Specifying the required argument types (function prototypes)

It is possible to specify the required argument types of functions exported from DLLs by setting the **argtypes** attribute.

**argtypes** must be a sequence of C data types (the `printf` function is probably not a good example here, because it takes a variable number and different types of parameters depending on the format string, on the other hand this is quite handy to experiment with this feature):

```

>>> printf.argtypes = [c_char_p, c_char_p, c_int, c_double]
>>> printf(b"String '%s', Int %d, Double %f\n", b"Hi", 10, 2.2)
String 'Hi', Int 10, Double 2.200000
37
>>>

```

Specifying a format protects against incompatible argument types (just as a prototype for a C function), and tries to convert the arguments to valid types:

```

>>> printf(b"%d %d %d", 1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: TypeError: wrong type
>>> printf(b"%s %d %f\n", b"X", 2, 3)
X 2 3.000000

```

13

>>>

If you have defined your own classes which you pass to function calls, you have to implement a **from\_param()** class method for them to be able to use them in the **argtypes** sequence. The **from\_param()** class method receives the Python object passed to the function call, it should do a typecheck or whatever is needed to make sure this object is acceptable, and then return the object itself, its **\_as\_parameter\_** attribute, or whatever you want to pass as the C function argument in this case. Again, the result should be an integer, string, bytes, a **ctypes** instance, or an object with an **\_as\_parameter\_** attribute.

## Return types

By default functions are assumed to return the C int type. Other return types can be specified by setting the **restype** attribute of the function object.

Here is a more advanced example, it uses the `strchr` function, which expects a string pointer and a char, and returns a pointer to a string:

```
>>> strchr = libc.strchr
>>> strchr(b"abcdef", ord("d"))
8059983
>>> strchr.restype = c_char_p      # c_char_p is a pointer
>>> strchr(b"abcdef", ord("d"))
b'def'
>>> print(strchr(b"abcdef", ord("x")))
None
>>>
```

If you want to avoid the `ord("x")` calls above, you can set the **argtypes** attribute, and the second argument will be converted from a single character Python bytes object into a C char:

```
>>> strchr.restype = c_char_p
>>> strchr.argtypes = [c_char_p, c_char]
```

```

>>> strchr(b"abcdef", b"d")
'def'
>>> strchr(b"abcdef", b"def")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: TypeError: one character string
>>> print(strchr(b"abcdef", b"x"))
None
>>> strchr(b"abcdef", b"d")
'def'
>>>

```

You can also use a callable Python object (a function or a class for example) as the **restype** attribute, if the foreign function returns an integer. The callable will be called with the *integer* the C function returns, and the result of this call will be used as the result of your function call. This is useful to check for error return values and automatically raise an exception:

```

>>> GetModuleHandle = windll.kernel32.GetModuleHandleA
>>> def ValidHandle(value):
...     if value == 0:
...         raise WinError()
...     return value
...
>>>
>>> GetModuleHandle.restype = ValidHandle
>>> GetModuleHandle(None)
486539264
>>> GetModuleHandle("something silly")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 3, in ValidHandle
OSError: [Errno 126] The specified module could not be found
>>>

```

`WinError` is a function which will call `Windows` `FormatMessage()` api to get the string representation of an error code, and *returns* an exception. `WinError` takes an optional error

code parameter, if no one is used, it calls `GetLastError()` to retrieve it.

Please note that a much more powerful error checking mechanism is available through the `errcheck` attribute; see the reference manual for details.

## Passing pointers (or: passing parameters by reference)

Sometimes a C api function expects a *pointer* to a data type as parameter, probably to write into the corresponding location, or if the data is too large to be passed by value. This is also known as *passing parameters by reference*.

`ctypes` exports the `byref()` function which is used to pass parameters by reference. The same effect can be achieved with the `pointer()` function, although `pointer()` does a lot more work since it constructs a real pointer object, so it is faster to use `byref()` if you don't need the pointer object in Python itself:

```
>>> i = c_int()
>>> f = c_float()
>>> s = create_string_buffer(b'\000' * 32)
>>> print(i.value, f.value, repr(s.value))
0 0.0 b''
>>> libc.sscanf(b"1 3.14 Hello", b"%d %f %s",
...             byref(i), byref(f), s)
3
>>> print(i.value, f.value, repr(s.value))
1 3.1400001049 b'Hello'
>>>
```

## Structures and unions

Structures and unions must derive from the `Structure` and `Union` base classes which are defined in the `ctypes` module. Each subclass must define a `_fields_` attribute. `_fields_` must be a list of 2-tuples, containing a *field name* and a *field type*.

The field type must be a `ctypes` type like `c_int`, or any other

derived **ctypes** type: structure, union, array, pointer.

Here is a simple example of a POINT structure, which contains two integers named *x* and *y*, and also shows how to initialize a structure in the constructor:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = [("x", c_int),
...                  ("y", c_int)]
...
>>> point = POINT(10, 20)
>>> print(point.x, point.y)
10 20
>>> point = POINT(y=5)
>>> print(point.x, point.y)
0 5
>>> POINT(1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: too many initializers
>>>
```

You can, however, build much more complicated structures. A structure can itself contain other structures by using a structure as a field type.

Here is a RECT structure which contains two POINTs named *upperleft* and *lowerright*:

```
>>> class RECT(Structure):
...     _fields_ = [("upperleft", POINT),
...                  ("lowerright", POINT)]
...
>>> rc = RECT(point)
>>> print(rc.upperleft.x, rc.upperleft.y)
0 5
>>> print(rc.lowerright.x, rc.lowerright.y)
0 0
>>>
```

Nested structures can also be initialized in the constructor in several ways:

```
>>> r = RECT(POINT(1, 2), POINT(3, 4))
>>> r = RECT((1, 2), (3, 4))
```

Field [descriptors](#) can be retrieved from the *class*, they are useful for debugging because they can provide useful information:

```
>>> print(POINT.x)
<Field type=c_long, ofs=0, size=4>
>>> print(POINT.y)
<Field type=c_long, ofs=4, size=4>
>>>
```

## Warning

[ctypes](#) does not support passing unions or structures with bit-fields to functions by value. While this may work on 32-bit x86, it's not guaranteed by the library to work in the general case. Unions and structures with bit-fields should always be passed to functions by pointer.

## Structure/union alignment and byte order

By default, Structure and Union fields are aligned in the same way the C compiler does it. It is possible to override this behavior by specifying a `\_pack\_` class attribute in the subclass definition. This must be set to a positive integer and specifies the maximum alignment for the fields. This is what `#pragma pack(n)` also does in MSVC.

[ctypes](#) uses the native byte order for Structures and Unions. To build structures with non-native byte order, you can use one of the [BigEndianStructure](#), [LittleEndianStructure](#), [BigEndianUnion](#), and [LittleEndianUnion](#) base classes. These classes cannot contain pointer fields.

## Bit fields in structures and unions

It is possible to create structures and unions containing bit fields. Bit fields are only possible for integer fields, the bit width is specified as the third item in the `_fields_` tuples:

```
>>> class Int(Structure):
...     _fields_ = [("first_16", c_int, 16),
...                 ("second_16", c_int, 16)]
...
>>> print(Int.first_16)
<Field type=c_long, ofs=0:0, bits=16>
>>> print(Int.second_16)
<Field type=c_long, ofs=0:16, bits=16>
>>>
```

## Arrays

Arrays are sequences, containing a fixed number of instances of the same type.

The recommended way to create array types is by multiplying a data type with a positive integer:

```
TenPointsArrayType = POINT * 10
```

Here is an example of a somewhat artificial data type, a structure containing 4 POINTs among other stuff:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class MyStruct(Structure):
...     _fields_ = [("a", c_int),
...                 ("b", c_float),
...                 ("point_array", POINT * 4)]
>>>
>>> print(len(MyStruct().point_array))
4
>>>
```

Instances are created in the usual way, by calling the class:

```
arr = TenPointsArrayType()
for pt in arr:
    print(pt.x, pt.y)
```

The above code print a series of 0 0 lines, because the array contents is initialized to zeros.

Initializers of the correct type can also be specified:

```
>>> from ctypes import *
>>> TenIntegers = c_int * 10
>>> ii = TenIntegers(1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
>>> print(ii)
<c_long_Array_10 object at 0x...>
>>> for i in ii: print(i, end=" ")
...
1 2 3 4 5 6 7 8 9 10
>>>
```

## Pointers

Pointer instances are created by calling the `pointer()` function on a `ctypes` type:

```
>>> from ctypes import *
>>> i = c_int(42)
>>> pi = pointer(i)
>>>
```

Pointer instances have a `contents` attribute which returns the object to which the pointer points, the `i` object above:

```
>>> pi.contents
c_long(42)
>>>
```

Note that `ctypes` does not have OOR (original object return), it constructs a new, equivalent object each time you retrieve an

attribute:

```
>>> pi.contents is i
False
>>> pi.contents is pi.contents
False
>>>
```

Assigning another `c_int` instance to the pointer's contents attribute would cause the pointer to point to the memory location where this is stored:

```
>>> i = c_int(99)
>>> pi.contents = i
>>> pi.contents
c_long(99)
>>>
```

Pointer instances can also be indexed with integers:

```
>>> pi[0]
99
>>>
```

Assigning to an integer index changes the pointed to value:

```
>>> print(i)
c_long(99)
>>> pi[0] = 22
>>> print(i)
c_long(22)
>>>
```

It is also possible to use indexes different from 0, but you must know what you're doing, just as in C: You can access or change arbitrary memory locations. Generally you only use this feature if you receive a pointer from a C function, and you *know* that the pointer actually points to an array instead of a single item.

Behind the scenes, the `pointer()` function does more than simply create pointer instances, it has to create pointer *types* first. This is

done with the `POINTER()` function, which accepts any `ctypes` type, and returns a new type:

```
>>> PI = POINTER(c_int)
>>> PI
<class 'ctypes.LP_c_long'>
>>> PI(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: expected c_long instead of int
>>> PI(c_int(42))
<ctypes.LP_c_long object at 0x...>
>>>
```

Calling the pointer type without an argument creates a `NULL` pointer. `NULL` pointers have a `False` boolean value:

```
>>> null_ptr = POINTER(c_int)()
>>> print(bool(null_ptr))
False
>>>
```

`ctypes` checks for `NULL` when dereferencing pointers (but dereferencing invalid non-`NULL` pointers would crash Python):

```
>>> null_ptr[0]
Traceback (most recent call last):
....
ValueError: NULL pointer access
>>>
```

```
>>> null_ptr[0] = 1234
Traceback (most recent call last):
....
ValueError: NULL pointer access
>>>
```

## Type conversions

Usually, `ctypes` does strict type checking. This means, if you have

`POINTER(c_int)` in the **argtypes** list of a function or as the type of a member field in a structure definition, only instances of exactly the same type are accepted. There are some exceptions to this rule, where `ctypes` accepts other objects. For example, you can pass compatible array instances instead of pointer types. So, for `POINTER(c_int)`, `ctypes` accepts an array of `c_int`:

```
>>> class Bar(Structure):
...     _fields_ = [("count", c_int), ("values", POINTER(c_int))]
...
>>> bar = Bar()
>>> bar.values = (c_int * 3)(1, 2, 3)
>>> bar.count = 3
>>> for i in range(bar.count):
...     print(bar.values[i])
...
1
2
3
>>>
```

In addition, if a function argument is explicitly declared to be a pointer type (such as `POINTER(c_int)`) in **argtypes**, an object of the pointed type (`c_int` in this case) can be passed to the function. `ctypes` will apply the required **byref()** conversion in this case automatically.

To set a `POINTER` type field to `NULL`, you can assign `None`:

```
>>> bar.values = None
>>>
```

Sometimes you have instances of incompatible types. In C, you can cast one type into another type. **ctypes** provides a **cast()** function which can be used in the same way. The `Bar` structure defined above accepts `POINTER(c_int)` pointers or **`c_int`** arrays for its `values` field, but not instances of other types:

```
>>> bar.values = (c_byte * 4)()
Traceback (most recent call last):
```

```
File "<stdin>", line 1, in <module>
TypeError: incompatible types, c_byte_Array_4 instance i
>>>
```

For these cases, the `cast()` function is handy.

The `cast()` function can be used to cast a ctypes instance into a pointer to a different ctypes data type. `cast()` takes two parameters, a ctypes object that is or can be converted to a pointer of some kind, and a ctypes pointer type. It returns an instance of the second argument, which references the same memory block as the first argument:

```
>>> a = (c_byte * 4)()
>>> cast(a, POINTER(c_int))
<ctypes.LP_c_long object at ...>
>>>
```

So, `cast()` can be used to assign to the `values` field of `Bar` the structure:

```
>>> bar = Bar()
>>> bar.values = cast((c_byte * 4)(), POINTER(c_int))
>>> print(bar.values[0])
0
>>>
```

## Incomplete Types

*Incomplete Types* are structures, unions or arrays whose members are not yet specified. In C, they are specified by forward declarations, which are defined later:

```
struct cell; /* forward declaration */

struct cell {
    char *name;
    struct cell *next;
};
```

The straightforward translation into ctypes code would be this, but it does not work:

```
>>> class cell(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("next", POINTER(cell))]
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in cell
NameError: name 'cell' is not defined
>>>
```

because the new class `cell` is not available in the class statement itself. In [ctypes](#), we can define the `cell` class and set the `_fields_` attribute later, after the class statement:

```
>>> from ctypes import *
>>> class cell(Structure):
...     pass
...
>>> cell._fields_ = [("name", c_char_p),
...                  ("next", POINTER(cell))]
>>>
```

Let's try it. We create two instances of `cell`, and let them point to each other, and finally follow the pointer chain a few times:

```
>>> c1 = cell()
>>> c1.name = b"foo"
>>> c2 = cell()
>>> c2.name = b"bar"
>>> c1.next = pointer(c2)
>>> c2.next = pointer(c1)
>>> p = c1
>>> for i in range(8):
...     print(p.name, end=" ")
...     p = p.next[0]
...
foo bar foo bar foo bar foo bar
```

```
>>>
```

## Callback functions

**ctypes** allows creating C callable function pointers from Python callables. These are sometimes called *callback functions*.

First, you must create a class for the callback function. The class knows the calling convention, the return type, and the number and types of arguments this function will receive.

The **CFUNCTYPE()** factory function creates types for callback functions using the `cdecl` calling convention. On Windows, the **WINFUNCTYPE()** factory function creates types for callback functions using the `stdcall` calling convention.

Both of these factory functions are called with the result type as first argument, and the callback functions expected argument types as the remaining arguments.

I will present an example here which uses the standard C library's **qsort()** function, that is used to sort items with the help of a callback function. **qsort()** will be used to sort an array of integers:

```
>>> IntArray5 = c_int * 5
>>> ia = IntArray5(5, 1, 7, 33, 99)
>>> qsort = libc.qsort
>>> qsort.restype = None
>>>
```

**qsort()** must be called with a pointer to the data to sort, the number of items in the data array, the size of one item, and a pointer to the comparison function, the callback. The callback will then be called with two pointers to items, and it must return a negative integer if the first item is smaller than the second, a zero if they are equal, and a positive integer otherwise.

So our callback function receives pointers to integers, and must return an integer. First we create the `type` for the callback function:

```
>>> CMPFUNC = CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
>>>
```

To get started, here is a simple callback that shows the values it gets passed:

```
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return 0
...
>>> cmp_func = CMPFUNC(py_cmp_func)
>>>
```

The result:

```
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 5 7
py_cmp_func 1 7
>>>
```

Now we can actually compare the two items and return a useful result:

```
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>>
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_func))
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>
```

As we can easily check, our array is sorted now:

```
>>> for i in ia: print(i, end=" ")
...
1 5 7 33 99
>>>
```

The function factories can be used as decorator factories, so we may as well write:

```
>>> @CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
... def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>> qsort(ia, len(ia), sizeof(c_int), py_cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>
```

## Note

Make sure you keep references to `CFUNCTYPE()` objects as long as they are used from C code. `ctypes` doesn't, and if you don't, they may be garbage collected, crashing your program when a callback is made.

Also, note that if the callback function is called in a thread created outside of Python's control (e.g. by the foreign code that calls the callback), `ctypes` creates a new dummy Python thread on every invocation. This behavior is correct for most purposes, but it means that values stored with `threading.local` will *not* survive across different callbacks, even when those calls are made from the same C thread.

## Accessing values exported from dlls

Some shared libraries not only export functions, they also export

variables. An example in the Python library itself is the `Py_OptimizeFlag`, an integer set to 0, 1, or 2, depending on the `-O` or `-OO` flag given on startup.

`ctypes` can access values like this with the `in_dll()` class methods of the type. `pythonapi` is a predefined symbol giving access to the Python C api:

```
>>> opt_flag = c_int.in_dll(pythonapi, "Py_OptimizeFlag")
>>> print(opt_flag)
c_long(0)
>>>
```

If the interpreter would have been started with `-O`, the sample would have printed `c_long(1)`, or `c_long(2)` if `-OO` would have been specified.

An extended example which also demonstrates the use of pointers accesses the `PyImport_FrozenModules` pointer exported by Python.

Quoting the docs for that value:

This pointer is initialized to point to an array of `_frozen` records, terminated by one whose members are all `NULL` or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

So manipulating this pointer could even prove useful. To restrict the example size, we show only how this table can be read with `ctypes`:

```
>>> from ctypes import *
>>>
>>> class struct_frozen(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("code", POINTER(c_ubyte)),
...                 ("size", c_int),
```

```

...             ("get_code", POINTER(c_ubyte)), # F
...         ]
...
>>>

```

We have defined the `_frozen` data type, so we can get the pointer to the table:

```

>>> FrozenTable = POINTER(struct_frozen)
>>> table = FrozenTable.in_dll(pythonapi, "_PyImport_Fro
>>>

```

Since `table` is a pointer to the array of `struct_frozen` records, we can iterate over it, but we just have to make sure that our loop terminates, because pointers have no size. Sooner or later it would probably crash with an access violation or whatever, so it's better to break out of the loop when we hit the `NULL` entry:

```

>>> for item in table:
...     if item.name is None:
...         break
...     print(item.name.decode("ascii"), item.size)
...
_frozen_importlib 31764
_frozen_importlib_external 41499
zipimport 12345
>>>

```

The fact that standard Python has a frozen module and a frozen package (indicated by the negative `size` member) is not well known, it is only used for testing. Try it out with `import __hello__` for example.

## Surprises

There are some edges in `ctypes` where you might expect something other than what actually happens.

Consider the following example:

```

>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class RECT(Structure):
...     _fields_ = ("a", POINT), ("b", POINT)
...
>>> p1 = POINT(1, 2)
>>> p2 = POINT(3, 4)
>>> rc = RECT(p1, p2)
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
1 2 3 4
>>> # now swap the two points
>>> rc.a, rc.b = rc.b, rc.a
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
3 4 3 4
>>>

```

Hm. We certainly expected the last statement to print 3 4 1 2. What happened? Here are the steps of the `rc.a, rc.b = rc.b, rc.a` line above:

```

>>> temp0, temp1 = rc.b, rc.a
>>> rc.a = temp0
>>> rc.b = temp1
>>>

```

Note that `temp0` and `temp1` are objects still using the internal buffer of the `rc` object above. So executing `rc.a = temp0` copies the buffer contents of `temp0` into `rc`'s buffer. This, in turn, changes the contents of `temp1`. So, the last assignment `rc.b = temp1`, doesn't have the expected effect.

Keep in mind that retrieving sub-objects from Structure, Unions, and Arrays doesn't *copy* the sub-object, instead it retrieves a wrapper object accessing the root-object's underlying buffer.

Another example that may behave differently from what one would expect is this:

```
>>> s = c_char_p()
>>> s.value = b"abc def ghi"
>>> s.value
b'abc def ghi'
>>> s.value is s.value
False
>>>
```

## Note

Objects instantiated from `c_char_p` can only have their value set to bytes or integers.

Why is it printing `False`? `ctypes` instances are objects containing a memory block plus some `descriptors` accessing the contents of the memory. Storing a Python object in the memory block does not store the object itself, instead the `contents` of the object is stored. Accessing the contents again constructs a new Python object each time!

## Variable-sized data types

`ctypes` provides some support for variable-sized arrays and structures.

The `resize()` function can be used to resize the memory buffer of an existing `ctypes` object. The function takes the object as first argument, and the requested size in bytes as the second argument. The memory block cannot be made smaller than the natural memory block specified by the objects type, a `ValueError` is raised if this is tried:

```
>>> short_array = (c_short * 4)()
>>> print(sizeof(short_array))
8
>>> resize(short_array, 4)
Traceback (most recent call last):
...
ValueError: minimum size is 8
```

```
>>> resize(short_array, 32)
>>> sizeof(short_array)
32
>>> sizeof(type(short_array))
8
>>>
```

This is nice and fine, but how would one access the additional elements contained in this array? Since the type still only knows about 4 elements, we get errors accessing other elements:

```
>>> short_array[:]
[0, 0, 0, 0]
>>> short_array[7]
Traceback (most recent call last):
...
IndexError: invalid index
>>>
```

Another way to use variable-sized data types with **ctypes** is to use the dynamic nature of Python, and (re-)define the data type after the required size is already known, on a case by case basis.

## ctypes reference

### Finding shared libraries

When programming in a compiled language, shared libraries are accessed when compiling/linking a program, and when the program is run.

The purpose of the **find\_library()** function is to locate a library in a way similar to what the compiler or runtime loader does (on platforms with several versions of a shared library the most recent should be loaded), while the ctypes library loaders act like when a program is run, and call the runtime loader directly.

The **ctypes.util** module provides a function which can help to determine the library to load.

`ctypes.util.find_library(name)`

Try to find a library and return a pathname. *name* is the library name without any prefix like *lib*, suffix like *.so*, *.dylib* or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

On Linux, **`find_library()`** tries to run external programs (`/sbin/ldconfig`, `gcc`, `objdump` and `ld`) to find the library file. It returns the filename of the library file.

*Changed in version 3.6:* On Linux, the value of the environment variable `LD_LIBRARY_PATH` is used when searching for libraries, if a library cannot be found by any other means.

Here are some examples:

```
>>> from ctypes.util import find_library
>>> find_library("m")
'libm.so.6'
>>> find_library("c")
'libc.so.6'
>>> find_library("bz2")
'libbz2.so.1.0'
>>>
```

On macOS, **`find_library()`** tries several predefined naming schemes and paths to locate the library, and returns a full pathname if successful:

```
>>> from ctypes.util import find_library
>>> find_library("c")
'/usr/lib/libc.dylib'
>>> find_library("m")
'/usr/lib/libm.dylib'
>>> find_library("bz2")
'/usr/lib/libbz2.dylib'
>>> find_library("AGL")
'/System/Library/Frameworks/AGL.framework/AGL'
```

>>>

On Windows, `find_library()` searches along the system search path, and returns the full pathname, but since there is no predefined naming scheme a call like `find_library("c")` will fail and return `None`.

If wrapping a shared library with `ctypes`, it *may* be better to determine the shared library name at development time, and hardcode that into the wrapper module instead of using `find_library()` to locate the library at runtime.

## Loading shared libraries

There are several ways to load shared libraries into the Python process. One way is to instantiate one of the following classes:

```
class ctypes.CDLL(name, mode=DEFAULT_MODE, handle=None,
use_errno=False, use_last_error=False, winmode=None)
```

Instances of this class represent loaded shared libraries. Functions in these libraries use the standard C calling convention, and are assumed to return int.

On Windows creating a `CDLL` instance may fail even if the DLL name exists. When a dependent DLL of the loaded DLL is not found, a `OSError` error is raised with the message “[WinError 126] The specified module could not be found”. This error message does not contain the name of the missing DLL because the Windows API does not return this information making this error hard to diagnose. To resolve this error and determine which DLL is not found, you need to find the list of dependent DLLs and determine which one is not found using Windows debugging and tracing tools.

### See also

**Microsoft DUMPBIN tool** [<https://docs.microsoft.com/cpp/build/reference/dependents>] – A tool to find DLL dependents.

*class ctypes.OleDLL(name, mode = DEFAULT\_MODE, handle = None, use\_errno = False, use\_last\_error = False, winmode = None)*

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return the windows specific **HRESULT** code. **HRESULT** values contain information specifying whether the function call failed or succeeded, together with additional error code. If the return value signals a failure, an **OSError** is automatically raised.

*Changed in version 3.3:* **WindowsError** used to be raised.

*class ctypes.WinDLL(name, mode = DEFAULT\_MODE, handle = None, use\_errno = False, use\_last\_error = False, winmode = None)*

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return int by default.

The Python **global interpreter lock** is released before calling any function exported by these libraries, and reacquired afterwards.

*class ctypes.PyDLL(name, mode = DEFAULT\_MODE, handle = None)*

Instances of this class behave like **CDLL** instances, except that the Python GIL is *not* released during the function call, and after the function execution the Python error flag is checked. If the error flag is set, a Python exception is raised.

Thus, this is only useful to call Python C api functions directly.

All these classes can be instantiated by calling them with at least one argument, the pathname of the shared library. If you have an existing handle to an already loaded shared library, it can be passed as the `handle` named parameter, otherwise the underlying platforms `dlopen` or `LoadLibrary` function is used to load the library into the process, and to get a handle to it.

The *mode* parameter can be used to specify how the library is loaded. For details, consult the **dlopen(3)** manpage. On Windows,

*mode* is ignored. On posix systems, `RTLD_NOW` is always added, and is not configurable.

The `use_errno` parameter, when set to true, enables a ctypes mechanism that allows accessing the system `errno` error number in a safe way. `ctypes` maintains a thread-local copy of the systems `errno` variable; if you call foreign functions created with `use_errno=True` then the `errno` value before the function call is swapped with the ctypes private copy, the same happens immediately after the function call.

The function `ctypes.get_errno()` returns the value of the ctypes private copy, and the function `ctypes.set_errno()` changes the ctypes private copy to a new value and returns the former value.

The `use_last_error` parameter, when set to true, enables the same mechanism for the Windows error code which is managed by the `GetLastError()` and `SetLastError()` Windows API functions; `ctypes.get_last_error()` and `ctypes.set_last_error()` are used to request and change the ctypes private copy of the windows error code.

The *winmode* parameter is used on Windows to specify how the library is loaded (since *mode* is ignored). It takes any value that is valid for the Win32 API `LoadLibraryEx` flags parameter. When omitted, the default is to use the flags that result in the most secure DLL load to avoiding issues such as DLL hijacking. Passing the full path to the DLL is the safest way to ensure the correct library and dependencies are loaded.

*Changed in version 3.8:* Added *winmode* parameter.

`ctypes.RTLD_GLOBAL`

Flag to use as *mode* parameter. On platforms where this flag is not available, it is defined as the integer zero.

`ctypes.RTLD_LOCAL`

Flag to use as *mode* parameter. On platforms where this is not available, it is the same as `RTLD_GLOBAL`.

## ctypes.DEFAULT\_MODE

The default mode which is used to load shared libraries. On OSX 10.3, this is *RTLD\_GLOBAL*, otherwise it is the same as *RTLD\_LOCAL*.

Instances of these classes have no public methods. Functions exported by the shared library can be accessed as attributes or by index. Please note that accessing the function through an attribute caches the result and therefore accessing it repeatedly returns the same object each time. On the other hand, accessing it through an index returns a new object each time:

```
>>> from ctypes import CDLL
>>> libc = CDLL("libc.so.6")    # On Linux
>>> libc.time == libc.time
True
>>> libc['time'] == libc['time']
False
```

The following public attributes are available, their name starts with an underscore to not clash with exported function names:

### PyDLL.\_handle

The system handle used to access the library.

### PyDLL.\_name

The name of the library passed in the constructor.

Shared libraries can also be loaded by using one of the prefabricated objects, which are instances of the [LibraryLoader](#) class, either by calling the **LoadLibrary()** method, or by retrieving the library as attribute of the loader instance.

### class ctypes.LibraryLoader(*dlltype*)

Class which loads shared libraries. *dlltype* should be one of the [CDLL](#), [PyDLL](#), [WinDLL](#), or [OleDLL](#) types.

**\_\_getattr\_\_()** has special behavior: It allows loading a shared library by accessing it as attribute of a library loader

instance. The result is cached, so repeated attribute accesses return the same library each time.

`LoadLibrary(name)`

Load a shared library into the process and return it. This method always returns a new instance of the library.

These prefabricated library loaders are available:

`ctypes.cdll`

Creates **CDLL** instances.

`ctypes.windll`

Windows only: Creates **WinDLL** instances.

`ctypes.oledll`

Windows only: Creates **OleDLL** instances.

`ctypes.pydll`

Creates **PyDLL** instances.

For accessing the C Python api directly, a ready-to-use Python shared library object is available:

`ctypes.pythonapi`

An instance of **PyDLL** that exposes Python C API functions as attributes. Note that all these functions are assumed to return C int, which is of course not always the truth, so you have to assign the correct **restype** attribute to use these functions.

Loading a library through any of these objects raises an **auditing event** `ctypes.dlopen` with string argument `name`, the name used to load the library.

Accessing a function on a loaded library raises an auditing event `ctypes.dlsym` with arguments `library` (the library object) and `name` (the symbol's name as a string or integer).

In cases when only the library handle is available rather than the object, accessing a function raises an auditing event `ctypes.dlsym/handle` with arguments `handle` (the raw library handle) and `name`.

## Foreign functions

As explained in the previous section, foreign functions can be accessed as attributes of loaded shared libraries. The function objects created in this way by default accept any number of arguments, accept any ctypes data instances as arguments, and return the default result type specified by the library loader. They are instances of a private class:

*class* `ctypes._FuncPtr`

Base class for C callable foreign functions.

Instances of foreign functions are also C compatible data types; they represent C function pointers.

This behavior can be customized by assigning to special attributes of the foreign function object.

*restype*

Assign a ctypes type to specify the result type of the foreign function. Use `None` for void, a function not returning anything.

It is possible to assign a callable Python object that is not a ctypes type, in this case the function is assumed to return a C int, and the callable will be called with this integer, allowing further processing or error checking. Using this is deprecated, for more flexible post processing or error checking use a ctypes data type as **`restype`** and assign a callable to the **`errcheck`** attribute.

*argtypes*

Assign a tuple of ctypes types to specify the argument types that the function accepts. Functions using the

`stdcall` calling convention can only be called with the same number of arguments as the length of this tuple; functions using the C calling convention accept additional, unspecified arguments as well.

When a foreign function is called, each actual argument is passed to the `from_param()` class method of the items in the `argtypes` tuple, this method allows adapting the actual argument to an object that the foreign function accepts. For example, a `c_char_p` item in the `argtypes` tuple will convert a string passed as argument into a bytes object using ctypes conversion rules.

New: It is now possible to put items in `argtypes` which are not ctypes types, but each item must have a `from_param()` method which returns a value usable as argument (integer, string, ctypes instance). This allows defining adapters that can adapt custom objects as function parameters.

## errcheck

Assign a Python function or another callable to this attribute. The callable will be called with three or more arguments:

`callable(result, func, arguments)`

*result* is what the foreign function returns, as specified by the `restype` attribute.

*func* is the foreign function object itself, this allows reusing the same callable object to check or post process the results of several functions.

*arguments* is a tuple containing the parameters originally passed to the function call, this allows specializing the behavior on the arguments used.

The object that this function returns will be returned from the foreign function call, but it can also check the

result value and raise an exception if the foreign function call failed.

*exception* `ctypes.ArgumentError`

This exception is raised when a foreign function call cannot convert one of the passed arguments.

On Windows, when a foreign function call raises a system exception (for example, due to an access violation), it will be captured and replaced with a suitable Python exception. Further, an auditing event `ctypes.seh_exception` with argument `code` will be raised, allowing an audit hook to replace the exception with its own.

Some ways to invoke foreign function calls may raise an auditing event `ctypes.call_function` with arguments `function pointer` and `arguments`.

## Function prototypes

Foreign functions can also be created by instantiating function prototypes. Function prototypes are similar to function prototypes in C; they describe a function (return type, argument types, calling convention) without defining an implementation. The factory functions must be called with the desired result type and the argument types of the function, and can be used as decorator factories, and as such, be applied to functions through the `@wrapper` syntax. See [Callback functions](#) for examples.

`ctypes.CFUNCTYPE(restype, *argtypes, use_errno=False, use_last_error=False)`

The returned function prototype creates functions that use the standard C calling convention. The function will release the GIL during the call. If `use_errno` is set to true, the `ctypes` private copy of the system `errno` variable is exchanged with the real `errno` value before and after the call; `use_last_error` does the same for the Windows error code.

`ctypes.WINFUNCTYPE(restype, *argtypes, use_errno=False,`

*use\_last\_error = False*)

Windows only: The returned function prototype creates functions that use the `stdcall` calling convention. The function will release the GIL during the call. *use\_errno* and *use\_last\_error* have the same meaning as above.

`ctypes.PYFUNCTYPE(restype, *argtypes)`

The returned function prototype creates functions that use the Python calling convention. The function will *not* release the GIL during the call.

Function prototypes created by these factory functions can be instantiated in different ways, depending on the type and number of the parameters in the call:

`prototype(address)`

Returns a foreign function at the specified address which must be an integer.

`prototype(callable)`

Create a C callable function (a callback function) from a Python *callable*.

`prototype(func_spec[, paramflags])`

Returns a foreign function exported by a shared library. *func\_spec* must be a 2-tuple (*name\_or\_ordinal*, *library*). The first item is the name of the exported function as string, or the ordinal of the exported function as small integer. The second item is the shared library instance.

`prototype(vtbl_index, name[, paramflags[, iid]])`

Returns a foreign function that will call a COM method. *vtbl\_index* is the index into the virtual function table, a small non-negative integer. *name* is name of the COM method. *iid*

is an optional pointer to the interface identifier which is used in extended error reporting.

COM methods use a special calling convention: They require a pointer to the COM interface as first argument, in addition to those parameters that are specified in the **argtypes** tuple.

The optional *paramflags* parameter creates foreign function wrappers with much more functionality than the features described above.

*paramflags* must be a tuple of the same length as **argtypes**.

Each item in this tuple contains further information about a parameter, it must be a tuple containing one, two, or three items.

The first item is an integer containing a combination of direction flags for the parameter:

- 1                      Specifies an input parameter to the function.
- 2                      Output parameter. The foreign function fills in a value.
- 4                      Input parameter which defaults to the integer zero.

The optional second item is the parameter name as string. If this is specified, the foreign function can be called with named parameters.

The optional third item is the default value for this parameter.

This example demonstrates how to wrap the Windows `MessageBoxW` function so that it supports default parameters and named arguments. The C declaration from the windows header file is this:

```
WINUSERAPI int WINAPI
MessageBoxW(
    HWND hWnd,
    LPCWSTR lpText,
    LPCWSTR lpCaption,
    UINT uType);
```

Here is the wrapping with `ctypes`:

```
>>> from ctypes import c_int, WINFUNCTYPE, windll
>>> from ctypes.wintypes import HWND, LPCWSTR, UINT
>>> prototype = WINFUNCTYPE(c_int, HWND, LPCWSTR, LPCWSTR)
>>> paramflags = (1, "hwnd", 0), (1, "text", "Hi"), (1,
>>> MessageBox = prototype(("MessageBoxW", windll.user32
```

The `MessageBox` foreign function can now be called in these ways:

```
>>> MessageBox()
>>> MessageBox(text="Spam, spam, spam")
>>> MessageBox(flags=2, text="foo bar")
```

A second example demonstrates output parameters. The win32 `GetWindowRect` function retrieves the dimensions of a specified window by copying them into `RECT` structure that the caller has to supply. Here is the C declaration:

```
WINUSERAPI BOOL WINAPI
GetWindowRect(
    HWND hWnd,
    LPRECT lpRect);
```

Here is the wrapping with `ctypes`:

```
>>> from ctypes import POINTER, WINFUNCTYPE, windll, Win
>>> from ctypes.wintypes import BOOL, HWND, RECT
>>> prototype = WINFUNCTYPE(BOOL, HWND, POINTER(RECT))
>>> paramflags = (1, "hwnd"), (2, "lprect")
>>> GetWindowRect = prototype(("GetWindowRect", windll.u
>>>
```

Functions with output parameters will automatically return the output parameter value if there is a single one, or a tuple containing the output parameter values when there are more than one, so the `GetWindowRect` function now returns a `RECT` instance, when called.

Output parameters can be combined with the **errcheck** protocol to do further output processing and error checking. The `win32` `GetWindowRect` api function returns a `BOOL` to signal success or failure, so this function could do the error checking, and raises an exception when the api call failed:

```
>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     return args
...
>>> GetWindowRect.errcheck = errcheck
>>>
```

If the **errcheck** function returns the argument tuple it receives unchanged, **ctypes** continues the normal processing it does on the output parameters. If you want to return a tuple of window coordinates instead of a `RECT` instance, you can retrieve the fields in the function and return them instead, the normal processing will no longer take place:

```
>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     rc = args[1]
...     return rc.left, rc.top, rc.bottom, rc.right
...
>>>
```

```
>>> GetWindowRect.errcheck = errcheck
>>>
```

## Utility functions

`ctypes.addressof(obj)`

Returns the address of the memory buffer as integer. *obj* must be an instance of a ctypes type.

Raises an [auditing event](#) `ctypes.addressof` with argument *obj*.

`ctypes.alignment(obj_or_type)`

Returns the alignment requirements of a ctypes type. *obj\_or\_type* must be a ctypes type or instance.

`ctypes.byref(obj[, offset])`

Returns a light-weight pointer to *obj*, which must be an instance of a ctypes type. *offset* defaults to zero, and must be an integer that will be added to the internal pointer value.

`byref(obj, offset)` corresponds to this C code:

```
((char *)&obj) + offset)
```

The returned object can only be used as a foreign function call parameter. It behaves similar to `pointer(obj)`, but the construction is a lot faster.

`ctypes.cast(obj, type)`

This function is similar to the cast operator in C. It returns a new instance of *type* which points to the same memory block as *obj*. *type* must be a pointer type, and *obj* must be an object that can be interpreted as a pointer.

`ctypes.create_string_buffer(init_or_size, size = None)`

This function creates a mutable character buffer. The returned object is a ctypes array of [c\\_char](#).

*init\_or\_size* must be an integer which specifies the size of the array, or a bytes object which will be used to initialize the array items.

If a bytes object is specified as first argument, the buffer is made one item larger than its length so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the bytes should not be used.

Raises an [auditing event](#) `ctypes.create_string_buffer` with arguments `init`, `size`.

`ctypes.create_unicode_buffer(init_or_size, size = None)`

This function creates a mutable unicode character buffer. The returned object is a ctypes array of [c\\_wchar](#).

*init\_or\_size* must be an integer which specifies the size of the array, or a string which will be used to initialize the array items.

If a string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the string should not be used.

Raises an [auditing event](#)

`ctypes.create_unicode_buffer` with arguments `init`, `size`.

`ctypes.DllCanUnloadNow()`

Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the `DllCanUnloadNow` function that the `_ctypes` extension dll exports.

`ctypes.DllGetClassObject()`

Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the `DllGetClassObject` function that the `_ctypes` extension dll exports.

`ctypes.util.find_library(name)`

Try to find a library and return a pathname. *name* is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

`ctypes.util.find_msvcr()`

Windows only: return the filename of the VC runtime library used by Python, and by the extension modules. If the name of the library cannot be determined, `None` is returned.

If you need to free memory, for example, allocated by an extension module with a call to the `free(void *)`, it is important that you use the function in the same library that allocated the memory.

`ctypes.FormatError([code])`

Windows only: Returns a textual description of the error code *code*. If no error code is specified, the last error code is used by calling the Windows api function `GetLastError`.

`ctypes.GetLastError()`

Windows only: Returns the last error code set by Windows in the calling thread. This function calls the Windows `GetLastError()` function directly, it does not return the ctypes-private copy of the error code.

`ctypes.get_errno()`

Returns the current value of the ctypes-private copy of the system `errno` variable in the calling thread.

Raises an [auditing event](#) `ctypes.get_errno` with no arguments.

`ctypes.get_last_error()`

Windows only: returns the current value of the ctypes-private copy of the system **LastError** variable in the calling thread.

Raises an [auditing event](#) `ctypes.get_last_error` with no arguments.

`ctypes.memmove(dst, src, count)`

Same as the standard C memmove library function: copies *count* bytes from *src* to *dst*. *dst* and *src* must be integers or ctypes instances that can be converted to pointers.

`ctypes.memset(dst, c, count)`

Same as the standard C memset library function: fills the memory block at address *dst* with *count* bytes of value *c*. *dst* must be an integer specifying an address, or a ctypes instance.

`ctypes.POINTER(type)`

This factory function creates and returns a new ctypes pointer type. Pointer types are cached and reused internally, so calling this function repeatedly is cheap. *type* must be a ctypes type.

`ctypes.pointer(obj)`

This function creates a new pointer instance, pointing to *obj*. The returned object is of the type `POINTER(type(obj))`.

Note: If you just want to pass a pointer to an object to a foreign function call, you should use `byref(obj)` which is much faster.

`ctypes.resize(obj, size)`

This function resizes the internal memory buffer of *obj*, which

must be an instance of a ctypes type. It is not possible to make the buffer smaller than the native size of the objects type, as given by `sizeof(type(obj))`, but it is possible to enlarge the buffer.

### `ctypes.set_errno(value)`

Set the current value of the ctypes-private copy of the system **errno** variable in the calling thread to *value* and return the previous value.

Raises an **auditing event** `ctypes.set_errno` with argument `errno`.

### `ctypes.set_last_error(value)`

Windows only: set the current value of the ctypes-private copy of the system **LastError** variable in the calling thread to *value* and return the previous value.

Raises an **auditing event** `ctypes.set_last_error` with argument `error`.

### `ctypes.sizeof(obj_or_type)`

Returns the size in bytes of a ctypes type or instance memory buffer. Does the same as the C `sizeof` operator.

### `ctypes.string_at(address, size=-1)`

This function returns the C string starting at memory address *address* as a bytes object. If *size* is specified, it is used as size, otherwise the string is assumed to be zero-terminated.

Raises an **auditing event** `ctypes.string_at` with arguments `address`, `size`.

### `ctypes.WinError(code=None, descr=None)`

Windows only: this function is probably the worst-named thing in ctypes. It creates an instance of `OSError`. If *code* is not specified, `GetLastError` is called to determine the error code. If *descr* is not specified, `FormatError()` is

called to get a textual description of the error.

*Changed in version 3.3:* An instance of `WindowsError` used to be created.

`ctypes.wstring_at(address, size = - 1)`

This function returns the wide character string starting at memory address *address* as a string. If *size* is specified, it is used as the number of characters of the string, otherwise the string is assumed to be zero-terminated.

Raises an `auditing event` `ctypes.wstring_at` with arguments *address*, *size*.

## Data types

`class ctypes._CData`

This non-public class is the common base class of all ctypes data types. Among other things, all ctypes type instances contain a memory block that hold C compatible data; the address of the memory block is returned by the `addressof()` helper function. Another instance variable is exposed as `_objects`; this contains other Python objects that need to be kept alive in case the memory block contains pointers.

Common methods of ctypes data types, these are all class methods (to be exact, they are methods of the `metaclass`):

`from_buffer(source[, offset])`

This method returns a ctypes instance that shares the buffer of the *source* object. The *source* object must support the writeable buffer interface. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a `ValueError` is raised.

Raises an `auditing event` `ctypes.cdata/buffer` with arguments *pointer*, *size*, *offset*.

`from_buffer_copy(source[, offset])`

This method creates a ctypes instance, copying the buffer from the *source* object buffer which must be readable. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a **ValueError** is raised.

Raises an **auditing event** `ctypes.cdata/buffer` with arguments `pointer`, `size`, `offset`.

`from_address(address)`

This method returns a ctypes type instance using the memory specified by *address* which must be an integer.

This method, and others that indirectly call this method, raises an **auditing event** `ctypes.cdata` with argument `address`.

`from_param(obj)`

This method adapts *obj* to a ctypes type. It is called with the actual object used in a foreign function call when the type is present in the foreign function's **argtypes** tuple; it must return an object that can be used as a function call parameter.

All ctypes data types have a default implementation of this classmethod that normally returns *obj* if that is an instance of the type. Some types accept other objects as well.

`in_dll(library, name)`

This method returns a ctypes type instance exported by a shared library. *name* is the name of the symbol that exports the data, *library* is the loaded shared library.

Common instance variables of ctypes data types:

## `_b_base_`

Sometimes ctypes data instances do not own the memory block they contain, instead they share part of the memory block of a base object. The `_b_base_` read-only member is the root ctypes object that owns the memory block.

## `_b_needsfree_`

This read-only variable is true when the ctypes data instance has allocated the memory block itself, false otherwise.

## `_objects`

This member is either `None` or a dictionary containing Python objects that need to be kept alive so that the memory block contents is kept valid. This object is only exposed for debugging; never modify the contents of this dictionary.

# Fundamental data types

## *class* `ctypes._SimpleCData`

This non-public class is the base class of all fundamental ctypes data types. It is mentioned here because it contains the common attributes of the fundamental ctypes data types.

`_SimpleCData` is a subclass of `_CData`, so it inherits their methods and attributes. ctypes data types that are not and do not contain pointers can now be pickled.

Instances have a single attribute:

## `value`

This attribute contains the actual value of the instance. For integer and pointer types, it is an integer, for character types, it is a single character bytes object or string, for character pointer types it is a Python bytes object or string.

When the `value` attribute is retrieved from a ctypes

instance, usually a new object is returned each time. `ctypes` does *not* implement original object return, always a new object is constructed. The same is true for all other ctypes object instances.

Fundamental data types, when returned as foreign function call results, or, for example, by retrieving structure field members or array items, are transparently converted to native Python types. In other words, if a foreign function has a **restype** of `c_char_p`, you will always receive a Python bytes object, *not* a `c_char_p` instance.

Subclasses of fundamental data types do *not* inherit this behavior. So, if a foreign functions **restype** is a subclass of `c_void_p`, you will receive an instance of this subclass from the function call. Of course, you can get the value of the pointer by accessing the `value` attribute.

These are the fundamental ctypes data types:

`class ctypes.c_byte`

Represents the C signed char datatype, and interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

`class ctypes.c_char`

Represents the C char datatype, and interprets the value as a single character. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

`class ctypes.c_char_p`

Represents the C char\* datatype when it points to a zero-terminated string. For a general character pointer that may also point to binary data, `POINTER(c_char)` must be used. The constructor accepts an integer address, or a bytes object.

`class ctypes.c_double`

Represents the C double datatype. The constructor accepts an

optional float initializer.

*class* ctypes.c\_longdouble

Represents the C long double datatype. The constructor accepts an optional float initializer. On platforms where `sizeof(long double) == sizeof(double)` it is an alias to `c_double`.

*class* ctypes.c\_float

Represents the C float datatype. The constructor accepts an optional float initializer.

*class* ctypes.c\_int

Represents the C signed int datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias to `c_long`.

*class* ctypes.c\_int8

Represents the C 8-bit signed int datatype. Usually an alias for `c_byte`.

*class* ctypes.c\_int16

Represents the C 16-bit signed int datatype. Usually an alias for `c_short`.

*class* ctypes.c\_int32

Represents the C 32-bit signed int datatype. Usually an alias for `c_int`.

*class* ctypes.c\_int64

Represents the C 64-bit signed int datatype. Usually an alias for `c_longlong`.

*class* ctypes.c\_long

Represents the C signed long datatype. The constructor accepts an optional integer initializer; no overflow checking is

done.

*class* ctypes.c\_longlong

Represents the C signed long long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

*class* ctypes.c\_short

Represents the C signed short datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

*class* ctypes.c\_size\_t

Represents the C **size\_t** datatype.

*class* ctypes.c\_ssize\_t

Represents the C **ssize\_t** datatype.

*New in version 3.2.*

*class* ctypes.c\_ubyte

Represents the C unsigned char datatype, it interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

*class* ctypes.c\_uint

Represents the C unsigned int datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias for **c\_ulong**.

*class* ctypes.c\_uint8

Represents the C 8-bit unsigned int datatype. Usually an alias for **c\_ubyte**.

*class* ctypes.c\_uint16

Represents the C 16-bit unsigned int datatype. Usually an

alias for `c_ushort`.

*class* `ctypes.c_uint32`

Represents the C 32-bit unsigned int datatype. Usually an alias for `c_uint`.

*class* `ctypes.c_uint64`

Represents the C 64-bit unsigned int datatype. Usually an alias for `c_ulonglong`.

*class* `ctypes.c_ulong`

Represents the C unsigned long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

*class* `ctypes.c_ulonglong`

Represents the C unsigned long long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

*class* `ctypes.c_ushort`

Represents the C unsigned short datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

*class* `ctypes.c_void_p`

Represents the C void\* type. The value is represented as integer. The constructor accepts an optional integer initializer.

*class* `ctypes.c_wchar`

Represents the C wchar\_t datatype, and interprets the value as a single character unicode string. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

*class* `ctypes.c_wchar_p`

Represents the C `wchar_t*` datatype, which must be a pointer to a zero-terminated wide character string. The constructor accepts an integer address, or a string.

*class* `ctypes.c_bool`

Represent the C `bool` datatype (more accurately, `_Bool` from C99). Its value can be `True` or `False`, and the constructor accepts any object that has a truth value.

*class* `ctypes.HRESULT`

Windows only: Represents a **HRESULT** value, which contains success or error information for a function or method call.

*class* `ctypes.py_object`

Represents the C `PyObject*` datatype. Calling this without an argument creates a `NULL PyObject*` pointer.

The `ctypes.wintypes` module provides quite some other Windows specific data types, for example **HWND**, **WPARAM**, or **DWORD**. Some useful structures like **MSG** or **RECT** are also defined.

## Structured data types

*class* `ctypes.Union(*args, **kw)`

Abstract base class for unions in native byte order.

*class* `ctypes.BigEndianUnion(*args, **kw)`

Abstract base class for unions in *big endian* byte order.

*New in version 3.11.*

*class* `ctypes.LittleEndianUnion(*args, **kw)`

Abstract base class for unions in *little endian* byte order.

*New in version 3.11.*

*class* `ctypes.BigEndianStructure(*args, **kw)`

Abstract base class for structures in *big endian* byte order.

```
class ctypes.LittleEndianStructure(*args, **kw)
```

Abstract base class for structures in *little endian* byte order.

Structures and unions with non-native byte order cannot contain pointer type fields, or any other data types containing pointer type fields.

```
class ctypes.Structure(*args, **kw)
```

Abstract base class for structures in *native* byte order.

Concrete structure and union types must be created by subclassing one of these types, and at least define a `fields` class variable. `ctypes` will create `descriptors` which allow reading and writing the fields by direct attribute accesses. These are the

`fields`

A sequence defining the structure fields. The items must be 2-tuples or 3-tuples. The first item is the name of the field, the second item specifies the type of the field; it can be any ctypes data type.

For integer type fields like `c_int`, a third optional item can be given. It must be a small positive integer defining the bit width of the field.

Field names must be unique within one structure or union. This is not checked, only one field can be accessed when names are repeated.

It is possible to define the `fields` class variable *after* the class statement that defines the Structure subclass, this allows creating data types that directly or indirectly reference themselves:

```
class List(Structure):
    pass
List._fields_ = [("pNext", POINTER(List)),
```

```
...  
]
```

The `__fields__` class variable must, however, be defined before the type is first used (an instance is created, `sizeof()` is called on it, and so on). Later assignments to the `__fields__` class variable will raise an `AttributeError`.

It is possible to define sub-subclasses of structure types, they inherit the fields of the base class plus the `__fields__` defined in the sub-subclass, if any.

#### `__pack__`

An optional small integer that allows overriding the alignment of structure fields in the instance. `__pack__` must already be defined when `__fields__` is assigned, otherwise it will have no effect.

#### `__anonymous__`

An optional sequence that lists the names of unnamed (anonymous) fields. `__anonymous__` must be already defined when `__fields__` is assigned, otherwise it will have no effect.

The fields listed in this variable must be structure or union type fields. `ctypes` will create descriptors in the structure type that allows accessing the nested fields directly, without the need to create the structure or union field.

Here is an example type (Windows):

```
class _U(Union):  
    __fields__ = [("lptdesc", POINTER(TYPEDESC)),  
                  ("lpadesc", POINTER(ARRAYDESC)),  
                  ("hreftype", HREFTYPE)]  
  
class TYPEDESC(Structure):  
    __anonymous__ = ("u",)
```

```
_fields_ = [("u", _U),
            ("vt", VARTYPE)]
```

The `TYPEDESC` structure describes a COM data type, the `vt` field specifies which one of the union fields is valid. Since the `u` field is defined as anonymous field, it is now possible to access the members directly off the `TYPEDESC` instance. `td.lptdesc` and `td.u.lptdesc` are equivalent, but the former is faster since it does not need to create a temporary union instance:

```
td = TYPEDESC()
td.vt = VT_PTR
td.lptdesc = POINTER(some_type)
td.u.lptdesc = POINTER(some_type)
```

It is possible to define sub-subclasses of structures, they inherit the fields of the base class. If the subclass definition has a separate `_fields_` variable, the fields specified in this are appended to the fields of the base class.

Structure and union constructors accept both positional and keyword arguments. Positional arguments are used to initialize member fields in the same order as they appear in `_fields_`. Keyword arguments in the constructor are interpreted as attribute assignments, so they will initialize `_fields_` with the same name, or create new attributes for names not present in `_fields_`.

## Arrays and pointers

```
class ctypes.Array(*args)
```

Abstract base class for arrays.

The recommended way to create concrete array types is by multiplying any `ctypes` data type with a non-negative integer. Alternatively, you can subclass this type and define `_length_` and `_type_` class variables. Array elements can be read and written using standard subscript and slice

accesses; for slice reads, the resulting object is *not* itself an **Array**.

**\_length\_**

A positive integer specifying the number of elements in the array. Out-of-range subscripts result in an **IndexError**. Will be returned by **len()**.

**\_type\_**

Specifies the type of each element in the array.

Array subclass constructors accept positional arguments, used to initialize the elements in order.

*class* ctypes.\_Pointer

Private, abstract base class for pointers.

Concrete pointer types are created by calling **POINTER()** with the type that will be pointed to; this is done automatically by **pointer()**.

If a pointer points to an array, its elements can be read and written using standard subscript and slice accesses. Pointer objects have no size, so **len()** will raise **TypeError**. Negative subscripts will read from the memory *before* the pointer (as in C), and out-of-range subscripts will probably crash with an access violation (if you're lucky).

**\_type\_**

Specifies the type pointed to.

**contents**

Returns the object to which the pointer points. Assigning to this attribute changes the pointer to point to the assigned object.

# Concurrent Execution

The modules described in this chapter provide support for concurrent execution of code. The appropriate choice of tool will depend on the task to be executed (CPU bound vs IO bound) and preferred style of development (event driven cooperative multitasking vs preemptive multitasking). Here's an overview:

- **threading** — Thread-based parallelism

- Thread-Local Data
- Thread Objects
- Lock Objects
- RLock Objects
- Condition Objects
- Semaphore Objects

- **Semaphore** Example

- Event Objects
- Timer Objects
- Barrier Objects
- Using locks, conditions, and semaphores in the **with** statement

- **multiprocessing** — Process-based parallelism

- Introduction
  - The **Process** class
  - Contexts and start methods
  - Exchanging objects between processes
  - Synchronization between processes
  - Sharing state between processes
  - Using a pool of workers
- Reference

- **Process** and exceptions
- Pipes and Queues
- Miscellaneous
- Connection Objects
- Synchronization primitives
- Shared **ctypes** Objects

- The **multiprocessing.sharedctypes** module

- Managers

- Customized managers
- Using a remote manager

- Proxy Objects

- Cleanup

- Process Pools
- Listeners and Clients

- Address Formats

- Authentication keys
- Logging
- The **multiprocessing.dummy** module

- Programming guidelines

- All start methods
- The *spawn* and *forkserver* start methods

- Examples

- **multiprocessing.shared\_memory** — Shared memory for direct access across processes
- The **concurrent** package
- **concurrent.futures** — Launching parallel tasks

- Executor Objects
- ThreadPoolExecutor

- ThreadPoolExecutor Example

- ProcessPoolExecutor

- ProcessPoolExecutor Example

- Future Objects
- Module Functions
- Exception classes

- **subprocess** — Subprocess management

- Using the **subprocess** Module

- Frequently Used Arguments
- Popen Constructor
- Exceptions

- Security Considerations
- Popen Objects
- Windows Popen Helpers

- Windows Constants

- Older high-level API
- Replacing Older Functions with the **subprocess** Module

- Replacing **/bin/sh** shell command substitution
- Replacing shell pipeline
- Replacing **os.system()**
- Replacing the **os.spawn** family
- Replacing **os.popen()**, **os.popen2()**, **os.popen3()**
- Replacing functions from the **popen2** module

- Legacy Shell Invocation Functions
- Notes

- Converting an argument sequence to a string on Windows
- Disabling use of **vfork()** or **posix\_spawn()**

- **sched** — Event scheduler
  - Scheduler Objects
- **queue** — A synchronized queue class
  - Queue Objects
  - SimpleQueue Objects
- **contextvars** — Context Variables
  - Context Variables
  - Manual Context Management
  - asyncio support

The following are support modules for some of the above services:

- **\_thread** — Low-level threading API

# threading — Thread-based parallelism

**Source code:** [Lib/threading.py](https://github.com/python/cpython/tree/3.11/Lib/threading.py) [https://github.com/python/cpython/tree/3.11/Lib/threading.py]

---

This module constructs higher-level threading interfaces on top of the lower level `_thread` module.

*Changed in version 3.7:* This module used to be optional, it is now always available.

## See also

`concurrent.futures.ThreadPoolExecutor` offers a higher level interface to push tasks to a background thread without blocking execution of the calling thread, while still being able to retrieve their results when needed.

`queue` provides a thread-safe interface for exchanging data between running threads.

`asyncio` offers an alternative approach to achieving task level concurrency without requiring the use of multiple operating system threads.

## Note

In the Python 2.x series, this module contained `camelCase` names for some methods and functions. These are deprecated as of Python 3.10, but they are still supported for compatibility with Python 2.5 and lower.

**CPython implementation detail:** In CPython, due to the [Global Interpreter Lock](#), only one thread can execute Python code at once (even though certain performance-oriented libraries might overcome this limitation). If you want your application to make better use of the computational resources of multi-core machines, you are advised to use [multiprocessing](#) or [concurrent.futures.ProcessPoolExecutor](#). However, threading is still an appropriate model if you want to run multiple I/O-bound tasks simultaneously.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

This module defines the following functions:

`threading.active_count()`

Return the number of [Thread](#) objects currently alive. The returned count is equal to the length of the list returned by [enumerate\(\)](#).

The function `activeCount` is a deprecated alias for this function.

`threading.current_thread()`

Return the current [Thread](#) object, corresponding to the caller's thread of control. If the caller's thread of control was not created through the [threading](#) module, a dummy thread object with limited functionality is returned.

The function `currentThread` is a deprecated alias for this function.

`threading.excepthook(args, /)`

Handle uncaught exception raised by [Thread.run\(\)](#).

The `args` argument has the following attributes:

- *exc\_type*: Exception type.
- *exc\_value*: Exception value, can be `None`.
- *exc\_traceback*: Exception traceback, can be `None`.
- *thread*: Thread which raised the exception, can be `None`.

If *exc\_type* is `SystemExit`, the exception is silently ignored. Otherwise, the exception is printed out on `sys.stderr`.

If this function raises an exception, `sys.excepthook()` is called to handle it.

`threading.excepthook()` can be overridden to control how uncaught exceptions raised by `Thread.run()` are handled.

Storing *exc\_value* using a custom hook can create a reference cycle. It should be cleared explicitly to break the reference cycle when the exception is no longer needed.

Storing *thread* using a custom hook can resurrect it if it is set to an object which is being finalized. Avoid storing *thread* after the custom hook completes to avoid resurrecting objects.

### See also

`sys.excepthook()` handles uncaught exceptions.

*New in version 3.8.*

### `threading._excepthook_`

Holds the original value of `threading.excepthook()`. It is saved so that the original value can be restored in case they happen to get replaced with broken or alternative objects.

*New in version 3.10.*

### `threading.get_ident()`

Return the ‘thread identifier’ of the current thread. This is a nonzero integer. Its value has no direct meaning; it is

intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

*New in version 3.3.*

`threading.get_native_id()`

Return the native integral Thread ID of the current thread assigned by the kernel. This is a non-negative integer. Its value may be used to uniquely identify this particular thread system-wide (until the thread terminates, after which the value may be recycled by the OS).

**Availability:** Windows, FreeBSD, Linux, macOS, OpenBSD, NetBSD, AIX.

*New in version 3.8.*

`threading.enumerate()`

Return a list of all **Thread** objects currently active. The list includes daemon threads and dummy thread objects created by `current_thread()`. It excludes terminated threads and threads that have not yet been started. However, the main thread is always part of the result, even when terminated.

`threading.main_thread()`

Return the main **Thread** object. In normal conditions, the main thread is the thread from which the Python interpreter was started.

*New in version 3.4.*

`threading.settrace(func)`

Set a trace function for all threads started from the **threading** module. The *func* will be passed to `sys.settrace()` for each thread, before its `run()` method is called.

`threading.gettrace()`

Get the trace function as set by `settrace()`.

*New in version 3.10.*

`threading.setprofile(func)`

Set a profile function for all threads started from the `threading` module. The *func* will be passed to `sys.setprofile()` for each thread, before its `run()` method is called.

`threading.getprofile()`

Get the profiler function as set by `setprofile()`.

*New in version 3.10.*

`threading.stack_size([size])`

Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, a `RuntimeError` is raised. If the specified stack size is invalid, a `ValueError` is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information).

**Availability:** Windows, pthreads.

Unix platforms with POSIX threads support.

This module also defines the following constant:

`threading.TIMEOUT_MAX`

The maximum value allowed for the *timeout* parameter of blocking functions (`Lock.acquire()`, `RLock.acquire()`, `Condition.wait()`, etc.). Specifying a timeout greater than this value will raise an `OverflowError`.

*New in version 3.2.*

This module defines a number of classes, which are detailed in the sections below.

The design of this module is loosely based on Java's threading model. However, where Java makes locks and condition variables basic behavior of every object, they are separate objects in Python. Python's `Thread` class supports a subset of the behavior of Java's `Thread` class; currently, there are no priorities, no thread groups, and threads cannot be destroyed, stopped, suspended, resumed, or interrupted. The static methods of Java's `Thread` class, when implemented, are mapped to module-level functions.

All of the methods described below are executed atomically.

## Thread-Local Data

Thread-local data is data whose values are thread specific. To manage thread-local data, just create an instance of `local` (or a subclass) and store attributes on it:

```
mydata = threading.local()
mydata.x = 1
```

The instance's values will be different for separate threads.

`class threading.local`

A class that represents thread-local data.

For more details and extensive examples, see the documentation string of the `_threading_local` module:

## Thread Objects

The **Thread** class represents an activity that is run in a separate thread of control. There are two ways to specify the activity: by passing a callable object to the constructor, or by overriding the **run()** method in a subclass. No other methods (except for the constructor) should be overridden in a subclass. In other words, only override the **\_\_init\_\_()** and **run()** methods of this class.

Once a thread object is created, its activity must be started by calling the thread's **start()** method. This invokes the **run()** method in a separate thread of control.

Once the thread's activity is started, the thread is considered 'alive'. It stops being alive when its **run()** method terminates – either normally, or by raising an unhandled exception. The **is\_alive()** method tests whether the thread is alive.

Other threads can call a thread's **join()** method. This blocks the calling thread until the thread whose **join()** method is called is terminated.

A thread has a name. The name can be passed to the constructor, and read or changed through the **name** attribute.

If the **run()** method raises an exception, **threading.excepthook()** is called to handle it. By default, **threading.excepthook()** ignores silently **SystemExit**.

A thread can be flagged as a “daemon thread”. The significance of this flag is that the entire Python program exits when only daemon threads are left. The initial value is inherited from the creating thread. The flag can be set through the **daemon** property or the *daemon* constructor argument.

### Note

Daemon threads are abruptly stopped at shutdown. Their resources (such as open files, database transactions, etc.) may not be released properly. If you want your threads to stop gracefully, make them non-daemonic and use a suitable signalling mechanism such as an [Event](#).

There is a “main thread” object; this corresponds to the initial thread of control in the Python program. It is not a daemon thread.

There is the possibility that “dummy thread objects” are created. These are thread objects corresponding to “alien threads”, which are threads of control started outside the threading module, such as directly from C code. Dummy thread objects have limited functionality; they are always considered alive and daemonic, and cannot be [joined](#). They are never deleted, since it is impossible to detect the termination of alien threads.

```
class threading.Thread(group = None, target = None, name = None,  
args = (), kwargs = {}, *, daemon = None)
```

This constructor should always be called with keyword arguments. Arguments are:

*group* should be *None*; reserved for future extension when a **ThreadGroup** class is implemented.

*target* is the callable object to be invoked by the [run\(\)](#) method. Defaults to *None*, meaning nothing is called.

*name* is the thread name. By default, a unique name is constructed of the form “Thread-*N*” where *N* is a small decimal number, or “Thread-*N* (*target*)” where “*target*” is `target.__name__` if the *target* argument is specified.

*args* is a list or tuple of arguments for the target invocation. Defaults to `()`.

*kwargs* is a dictionary of keyword arguments for the target invocation. Defaults to `{}`.

If not *None*, *daemon* explicitly sets whether the thread is

daemon. If `None` (the default), the daemon property is inherited from the current thread.

If the subclass overrides the constructor, it must make sure to invoke the base class constructor (`Thread.__init__()`) before doing anything else to the thread.

*Changed in version 3.10:* Use the *target* name if *name* argument is omitted.

*Changed in version 3.3:* Added the *daemon* argument.

`start()`

Start the thread's activity.

It must be called at most once per thread object. It arranges for the object's `run()` method to be invoked in a separate thread of control.

This method will raise a `RuntimeError` if called more than once on the same thread object.

`run()`

Method representing the thread's activity.

You may override this method in a subclass. The standard `run()` method invokes the callable object passed to the object's constructor as the *target* argument, if any, with positional and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

Using list or tuple as the *args* argument which passed to the `Thread` could achieve the same effect.

Example:

```
>>> from threading import Thread
>>> t = Thread(target=print, args=[1])
>>> t.run()
```

```
1
>>> t = Thread(target=print, args=(1,))
>>> t.run()
1
```

### `join(timeout=None)`

Wait until the thread terminates. This blocks the calling thread until the thread whose `join()` method is called terminates – either normally or through an unhandled exception – or until the optional timeout occurs.

When the *timeout* argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof). As `join()` always returns `None`, you must call `is_alive()` after `join()` to decide whether a timeout happened – if the thread is still alive, the `join()` call timed out.

When the *timeout* argument is not present or `None`, the operation will block until the thread terminates.

A thread can be joined many times.

`join()` raises a `RuntimeError` if an attempt is made to join the current thread as that would cause a deadlock. It is also an error to `join()` a thread before it has been started and attempts to do so raise the same exception.

### `name`

A string used for identification purposes only. It has no semantics. Multiple threads may be given the same name. The initial name is set by the constructor.

### `getName()`

setName()

Deprecated getter/setter API for `name`; use it directly as a property instead.

*Deprecated since version 3.10.*

ident

The ‘thread identifier’ of this thread or `None` if the thread has not been started. This is a nonzero integer. See the `get_ident()` function. Thread identifiers may be recycled when a thread exits and another thread is created. The identifier is available even after the thread has exited.

native\_id

The Thread ID (TID) of this thread, as assigned by the OS (kernel). This is a non-negative integer, or `None` if the thread has not been started. See the `get_native_id()` function. This value may be used to uniquely identify this particular thread system-wide (until the thread terminates, after which the value may be recycled by the OS).

### Note

Similar to Process IDs, Thread IDs are only valid (guaranteed unique system-wide) from the time the thread is created until the thread has been terminated.

**Availability:** Windows, FreeBSD, Linux, macOS, OpenBSD, NetBSD, AIX, DragonFlyBSD.

*New in version 3.8.*

is\_alive()

Return whether the thread is alive.

This method returns `True` just before the `run()`

method starts until just after the `run()` method terminates. The module function `enumerate()` returns a list of all alive threads.

### daemon

A boolean value indicating whether this thread is a daemon thread (`True`) or not (`False`). This must be set before `start()` is called, otherwise `RuntimeError` is raised. Its initial value is inherited from the creating thread; the main thread is not a daemon thread and therefore all threads created in the main thread default to `daemon = False`.

The entire Python program exits when no alive non-daemon threads are left.

`isDaemon()`

`setDaemon()`

Deprecated getter/setter API for `daemon`; use it directly as a property instead.

*Deprecated since version 3.10.*

## Lock Objects

A primitive lock is a synchronization primitive that is not owned by a particular thread when locked. In Python, it is currently the lowest level synchronization primitive available, implemented directly by the `_thread` extension module.

A primitive lock is in one of two states, “locked” or “unlocked”. It is created in the unlocked state. It has two basic methods, `acquire()` and `release()`. When the state is unlocked, `acquire()` changes the state to locked and returns immediately. When the state is locked, `acquire()` blocks until a call to `release()` in another thread changes it to unlocked, then the `acquire()` call resets it to locked and returns. The `release()` method should only be called in the locked state; it changes the state to unlocked and returns immediately. If an attempt is made to

release an unlocked lock, a `RuntimeError` will be raised.

Locks also support the [context management protocol](#).

When more than one thread is blocked in `acquire()` waiting for the state to turn to unlocked, only one thread proceeds when a `release()` call resets the state to unlocked; which one of the waiting threads proceeds is not defined, and may vary across implementations.

All methods are executed atomically.

*class* threading.Lock

The class implementing primitive lock objects. Once a thread has acquired a lock, subsequent attempts to acquire it block, until it is released; any thread may release it.

Note that `Lock` is actually a factory function which returns an instance of the most efficient version of the concrete `Lock` class that is supported by the platform.

`acquire(blocking=True, timeout=-1)`

Acquire a lock, blocking or non-blocking.

When invoked with the *blocking* argument set to `True` (the default), block until the lock is unlocked, then set it to locked and return `True`.

When invoked with the *blocking* argument set to `False`, do not block. If a call with *blocking* set to `True` would block, return `False` immediately; otherwise, set the lock to locked and return `True`.

When invoked with the floating-point *timeout* argument set to a positive value, block for at most the number of seconds specified by *timeout* and as long as the lock cannot be acquired. A *timeout* argument of `-1` specifies an unbounded wait. It is forbidden to specify a *timeout* when *blocking* is `False`.

The return value is `True` if the lock is acquired

successfully, `False` if not (for example if the *timeout* expired).

*Changed in version 3.2:* The *timeout* parameter is new.

*Changed in version 3.2:* Lock acquisition can now be interrupted by signals on POSIX if the underlying threading implementation supports it.

`release()`

Release a lock. This can be called from any thread, not only the thread which has acquired the lock.

When the lock is locked, reset it to unlocked, and return. If any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a `RuntimeError` is raised.

There is no return value.

`locked()`

Return `True` if the lock is acquired.

## RLock Objects

A reentrant lock is a synchronization primitive that may be acquired multiple times by the same thread. Internally, it uses the concepts of “owning thread” and “recursion level” in addition to the locked/unlocked state used by primitive locks. In the locked state, some thread owns the lock; in the unlocked state, no thread owns it.

To lock the lock, a thread calls its `acquire()` method; this returns once the thread owns the lock. To unlock the lock, a thread calls its `release()` method. `acquire()/release()` call pairs may be nested; only the final `release()` (the `release()` of the outermost pair) resets the lock to unlocked and allows another

thread blocked in `acquire()` to proceed.

Reentrant locks also support the `context management protocol`.

*class* `threading.RLock`

This class implements reentrant lock objects. A reentrant lock must be released by the thread that acquired it. Once a thread has acquired a reentrant lock, the same thread may acquire it again without blocking; the thread must release it once for each time it has acquired it.

Note that `RLock` is actually a factory function which returns an instance of the most efficient version of the concrete `RLock` class that is supported by the platform.

`acquire(blocking=True, timeout=-1)`

Acquire a lock, blocking or non-blocking.

When invoked without arguments: if this thread already owns the lock, increment the recursion level by one, and return immediately. Otherwise, if another thread owns the lock, block until the lock is unlocked. Once the lock is unlocked (not owned by any thread), then grab ownership, set the recursion level to one, and return. If more than one thread is blocked waiting until the lock is unlocked, only one at a time will be able to grab ownership of the lock. There is no return value in this case.

When invoked with the *blocking* argument set to `True`, do the same thing as when called without arguments, and return `True`.

When invoked with the *blocking* argument set to `False`, do not block. If a call without an argument would block, return `False` immediately; otherwise, do the same thing as when called without arguments, and return `True`.

When invoked with the floating-point *timeout* argument set to a positive value, block for at most the number of

seconds specified by *timeout* and as long as the lock cannot be acquired. Return `True` if the lock has been acquired, `False` if the timeout has elapsed.

*Changed in version 3.2:* The *timeout* parameter is new.

`release()`

Release a lock, decrementing the recursion level. If after the decrement it is zero, reset the lock to unlocked (not owned by any thread), and if any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling thread.

Only call this method when the calling thread owns the lock. A `RuntimeError` is raised if this method is called when the lock is unlocked.

There is no return value.

## Condition Objects

A condition variable is always associated with some kind of lock; this can be passed in or one will be created by default. Passing one in is useful when several condition variables must share the same lock. The lock is part of the condition object: you don't have to track it separately.

A condition variable obeys the [context management protocol](#): using the `with` statement acquires the associated lock for the duration of the enclosed block. The `acquire()` and `release()` methods also call the corresponding methods of the associated lock.

Other methods must be called with the associated lock held. The `wait()` method releases the lock, and then blocks until another thread awakens it by calling `notify()` or `notify_all()`. Once awakened, `wait()` re-acquires the lock and returns. It is also possible to specify a timeout.

The `notify()` method wakes up one of the threads waiting for the condition variable, if any are waiting. The `notify_all()` method wakes up all threads waiting for the condition variable.

Note: the `notify()` and `notify_all()` methods don't release the lock; this means that the thread or threads awakened will not return from their `wait()` call immediately, but only when the thread that called `notify()` or `notify_all()` finally relinquishes ownership of the lock.

The typical programming style using condition variables uses the lock to synchronize access to some shared state; threads that are interested in a particular change of state call `wait()` repeatedly until they see the desired state, while threads that modify the state call `notify()` or `notify_all()` when they change the state in such a way that it could possibly be a desired state for one of the waiters. For example, the following code is a generic producer-consumer situation with unlimited buffer capacity:

```
# Consume one item
with cv:
    while not an_item_is_available():
        cv.wait()
    get_an_available_item()

# Produce one item
with cv:
    make_an_item_available()
    cv.notify()
```

The `while` loop checking for the application's condition is necessary because `wait()` can return after an arbitrary long time, and the condition which prompted the `notify()` call may no longer hold true. This is inherent to multi-threaded programming. The `wait_for()` method can be used to automate the condition checking, and eases the computation of timeouts:

```
# Consume an item
with cv:
    cv.wait_for(an_item_is_available)
```

```
get_an_available_item()
```

To choose between `notify()` and `notify_all()`, consider whether one state change can be interesting for only one or several waiting threads. E.g. in a typical producer-consumer situation, adding one item to the buffer only needs to wake up one consumer thread.

```
class threading.Condition(lock=None)
```

This class implements condition variable objects. A condition variable allows one or more threads to wait until they are notified by another thread.

If the *lock* argument is given and not `None`, it must be a `Lock` or `RLock` object, and it is used as the underlying lock. Otherwise, a new `RLock` object is created and used as the underlying lock.

*Changed in version 3.3:* changed from a factory function to a class.

```
acquire(*args)
```

Acquire the underlying lock. This method calls the corresponding method on the underlying lock; the return value is whatever that method returns.

```
release()
```

Release the underlying lock. This method calls the corresponding method on the underlying lock; there is no return value.

```
wait(timeout=None)
```

Wait until notified or until a timeout occurs. If the calling thread has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method releases the underlying lock, and then blocks until it is awakened by a `notify()` or `notify_all()` call for the same condition variable in

another thread, or until the optional timeout occurs. Once awakened or timed out, it re-acquires the lock and returns.

When the *timeout* argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

When the underlying lock is an `RLock`, it is not released using its `release()` method, since this may not actually unlock the lock when it was acquired multiple times recursively. Instead, an internal interface of the `RLock` class is used, which really unlocks it even when it has been recursively acquired several times. Another internal interface is then used to restore the recursion level when the lock is reacquired.

The return value is `True` unless a given *timeout* expired, in which case it is `False`.

*Changed in version 3.2:* Previously, the method always returned `None`.

`wait_for(predicate, timeout=None)`

Wait until a condition evaluates to true. *predicate* should be a callable which result will be interpreted as a boolean value. A *timeout* may be provided giving the maximum time to wait.

This utility method may call `wait()` repeatedly until the predicate is satisfied, or until a timeout occurs. The return value is the last return value of the predicate and will evaluate to `False` if the method timed out.

Ignoring the timeout feature, calling this method is roughly equivalent to writing:

```
while not predicate():
    cv.wait()
```

Therefore, the same rules apply as with `wait()`: The

lock must be held when called and is re-acquired on return. The predicate is evaluated with the lock held.

*New in version 3.2.*

`notify( $n=1$ )`

By default, wake up one thread waiting on this condition, if any. If the calling thread has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method wakes up at most  $n$  of the threads waiting for the condition variable; it is a no-op if no threads are waiting.

The current implementation wakes up exactly  $n$  threads, if at least  $n$  threads are waiting. However, it's not safe to rely on this behavior. A future, optimized implementation may occasionally wake up more than  $n$  threads.

Note: an awakened thread does not actually return from its `wait()` call until it can reacquire the lock. Since `notify()` does not release the lock, its caller should.

`notify_all()`

Wake up all threads waiting on this condition. This method acts like `notify()`, but wakes up all waiting threads instead of one. If the calling thread has not acquired the lock when this method is called, a `RuntimeError` is raised.

The method `notifyAll` is a deprecated alias for this method.

## Semaphore Objects

This is one of the oldest synchronization primitives in the history of

computer science, invented by the early Dutch computer scientist Edsger W. Dijkstra (he used the names `P()` and `V()` instead of `acquire()` and `release()`).

A semaphore manages an internal counter which is decremented by each `acquire()` call and incremented by each `release()` call. The counter can never go below zero; when `acquire()` finds that it is zero, it blocks, waiting until some other thread calls `release()`.

Semaphores also support the [context management protocol](#).

`class threading.Semaphore(value = 1)`

This class implements semaphore objects. A semaphore manages an atomic counter representing the number of `release()` calls minus the number of `acquire()` calls, plus an initial value. The `acquire()` method blocks if necessary until it can return without making the counter negative. If not given, `value` defaults to 1.

The optional argument gives the initial `value` for the internal counter; it defaults to 1. If the `value` given is less than 0, `ValueError` is raised.

*Changed in version 3.3:* changed from a factory function to a class.

`acquire(blocking = True, timeout = None)`

Acquire a semaphore.

When invoked without arguments:

- If the internal counter is larger than zero on entry, decrement it by one and return `True` immediately.
- If the internal counter is zero on entry, block until awoken by a call to `release()`. Once awoken (and the counter is greater than 0), decrement the counter by 1 and return `True`. Exactly one thread will be awoken by each call to

`release()`. The order in which threads are awoken should not be relied on.

When invoked with *blocking* set to `False`, do not block. If a call without an argument would block, return `False` immediately; otherwise, do the same thing as when called without arguments, and return `True`.

When invoked with a *timeout* other than `None`, it will block for at most *timeout* seconds. If acquire does not complete successfully in that interval, return `False`. Return `True` otherwise.

*Changed in version 3.2:* The *timeout* parameter is new.

`release(n=1)`

Release a semaphore, incrementing the internal counter by *n*. When it was zero on entry and other threads are waiting for it to become larger than zero again, wake up *n* of those threads.

*Changed in version 3.9:* Added the *n* parameter to release multiple waiting threads at once.

`class threading.BoundedSemaphore(value=1)`

Class implementing bounded semaphore objects. A bounded semaphore checks to make sure its current value doesn't exceed its initial value. If it does, `ValueError` is raised. In most situations semaphores are used to guard resources with limited capacity. If the semaphore is released too many times it's a sign of a bug. If not given, *value* defaults to 1.

*Changed in version 3.3:* changed from a factory function to a class.

## Semaphore Example

Semaphores are often used to guard resources with limited capacity,

for example, a database server. In any situation where the size of the resource is fixed, you should use a bounded semaphore. Before spawning any worker threads, your main thread would initialize the semaphore:

```
maxconnections = 5
# ...
pool_sema = BoundedSemaphore(value=maxconnections)
```

Once spawned, worker threads call the semaphore's `acquire` and `release` methods when they need to connect to the server:

```
with pool_sema:
    conn = connectdb()
    try:
        # ... use connection ...
    finally:
        conn.close()
```

The use of a bounded semaphore reduces the chance that a programming error which causes the semaphore to be released more than it's acquired will go undetected.

## Event Objects

This is one of the simplest mechanisms for communication between threads: one thread signals an event and other threads wait for it.

An event object manages an internal flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true.

*class* `threading.Event`

Class implementing event objects. An event manages a flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true. The flag is initially false.

*Changed in version 3.3:* changed from a factory function to a class.

`is_set()`

Return `True` if and only if the internal flag is true.

The method `isSet` is a deprecated alias for this method.

`set()`

Set the internal flag to true. All threads waiting for it to become true are awakened. Threads that call `wait()` once the flag is true will not block at all.

`clear()`

Reset the internal flag to false. Subsequently, threads calling `wait()` will block until `set()` is called to set the internal flag to true again.

`wait(timeout=None)`

Block until the internal flag is true. If the internal flag is true on entry, return immediately. Otherwise, block until another thread calls `set()` to set the flag to true, or until the optional timeout occurs.

When the timeout argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

This method returns `True` if and only if the internal flag has been set to true, either before the wait call or after the wait starts, so it will always return `True` except if a timeout is given and the operation times out.

*Changed in version 3.1:* Previously, the method always returned `None`.

## Timer Objects

This class represents an action that should be run only after a

certain amount of time has passed — a timer. **Timer** is a subclass of **Thread** and as such also functions as an example of creating custom threads.

Timers are started, as with threads, by calling their **start()** method. The timer can be stopped (before its action has begun) by calling the **cancel()** method. The interval the timer will wait before executing its action may not be exactly the same as the interval specified by the user.

For example:

```
def hello():
    print("hello, world")

t = Timer(30.0, hello)
t.start() # after 30 seconds, "hello, world" will be pr
```

**class** `threading.Timer(interval, function, args=None, kwargs=None)`

Create a timer that will run *function* with arguments *args* and keyword arguments *kwargs*, after *interval* seconds have passed. If *args* is `None` (the default) then an empty list will be used. If *kwargs* is `None` (the default) then an empty dict will be used.

*Changed in version 3.3:* changed from a factory function to a class.

**cancel()**

Stop the timer, and cancel the execution of the timer's action. This will only work if the timer is still in its waiting stage.

## Barrier Objects

*New in version 3.2.*

This class provides a simple synchronization primitive for use by a fixed number of threads that need to wait for each other. Each of

the threads tries to pass the barrier by calling the `wait()` method and will block until all of the threads have made their `wait()` calls. At this point, the threads are released simultaneously.

The barrier can be reused any number of times for the same number of threads.

As an example, here is a simple way to synchronize a client and server thread:

```
b = Barrier(2, timeout=5)

def server():
    start_server()
    b.wait()
    while True:
        connection = accept_connection()
        process_server_connection(connection)

def client():
    b.wait()
    while True:
        connection = make_connection()
        process_client_connection(connection)
```

*class threading.Barrier(parties, action=None, timeout=None)*

Create a barrier object for *parties* number of threads. An *action*, when provided, is a callable to be called by one of the threads when they are released. *timeout* is the default timeout value if none is specified for the `wait()` method.

*wait(timeout=None)*

Pass the barrier. When all the threads party to the barrier have called this function, they are all released simultaneously. If a *timeout* is provided, it is used in preference to any that was supplied to the class constructor.

The return value is an integer in the range 0 to *parties* – 1, different for each thread. This can be used to select a

thread to do some special housekeeping, e.g.:

```
i = barrier.wait()
if i == 0:
    # Only one thread needs to print this
    print("passed the barrier")
```

If an *action* was provided to the constructor, one of the threads will have called it prior to being released. Should this call raise an error, the barrier is put into the broken state.

If the call times out, the barrier is put into the broken state.

This method may raise a **BrokenBarrierError** exception if the barrier is broken or reset while a thread is waiting.

### reset()

Return the barrier to the default, empty state. Any threads waiting on it will receive the **BrokenBarrierError** exception.

Note that using this function may require some external synchronization if there are other threads whose state is unknown. If a barrier is broken it may be better to just leave it and create a new one.

### abort()

Put the barrier into a broken state. This causes any active or future calls to **wait()** to fail with the **BrokenBarrierError**. Use this for example if one of the threads needs to abort, to avoid deadlocking the application.

It may be preferable to simply create the barrier with a sensible *timeout* value to automatically guard against one of the threads going awry.

`parties`

The number of threads required to pass the barrier.

`n_waiting`

The number of threads currently waiting in the barrier.

`broken`

A boolean that is `True` if the barrier is in the broken state.

*exception* `threading.BrokenBarrierError`

This exception, a subclass of `RuntimeError`, is raised when the `Barrier` object is reset or broken.

## Using locks, conditions, and semaphores in the `with` statement

All of the objects provided by this module that have `acquire()` and `release()` methods can be used as context managers for a `with` statement. The `acquire()` method will be called when the block is entered, and `release()` will be called when the block is exited. Hence, the following snippet:

```
with some_lock:
    # do something...
```

is equivalent to:

```
some_lock.acquire()
try:
    # do something...
finally:
    some_lock.release()
```

Currently, `Lock`, `RLock`, `Condition`, `Semaphore`, and `BoundedSemaphore` objects may be used as `with` statement context managers.

# **multiprocessing** — Process-based parallelism

**Source code:** [Lib/multiprocessing/](https://github.com/python/cpython/tree/3.11/Lib/multiprocessing/) [https://github.com/python/cpython/tree/3.11/Lib/multiprocessing/]

---

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

## Introduction

**multiprocessing** is a package that supports spawning processes using an API similar to the **threading** module. The **multiprocessing** package offers both local and remote concurrency, effectively side-stepping the [Global Interpreter Lock](#) by using subprocesses instead of threads. Due to this, the **multiprocessing** module allows the programmer to fully leverage multiple processors on a given machine. It runs on both Unix and Windows.

The **multiprocessing** module also introduces APIs which do not have analogs in the **threading** module. A prime example of this is the **Pool** object which offers a convenient means of parallelizing the execution of a function across multiple input values, distributing the input data across processes (data parallelism). The following example demonstrates the common practice of defining such functions in a module so that child processes can successfully import that module. This basic example of data parallelism using **Pool**,

```
from multiprocessing import Pool
```

```
def f(x):
    return x*x

if __name__ == '__main__':
    with Pool(5) as p:
        print(p.map(f, [1, 2, 3]))
```

will print to standard output

```
[1, 4, 9]
```

### See also

[`concurrent.futures.ProcessPoolExecutor`](#) offers a higher level interface to push tasks to a background process without blocking execution of the calling process. Compared to using the [`Pool`](#) interface directly, the [`concurrent.futures`](#) API more readily allows the submission of work to the underlying process pool to be separated from waiting for the results.

## The [`Process`](#) class

In [`multiprocessing`](#), processes are spawned by creating a [`Process`](#) object and then calling its [`start\(\)`](#) method. [`Process`](#) follows the API of [`threading.Thread`](#). A trivial example of a multiprocess program is

```
from multiprocessing import Process

def f(name):
    print('hello', name)

if __name__ == '__main__':
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

To show the individual process IDs involved, here is an expanded example:

```
from multiprocessing import Process
import os

def info(title):
    print(title)
    print('module name:', __name__)
    print('parent process:', os.getppid())
    print('process id:', os.getpid())

def f(name):
    info('function f')
    print('hello', name)

if __name__ == '__main__':
    info('main line')
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

For an explanation of why the `if __name__ == '__main__':` part is necessary, see [Programming guidelines](#).

## Contexts and start methods

Depending on the platform, **multiprocessing** supports three ways to start a process. These *start methods* are

### *spawn*

The parent process starts a fresh Python interpreter process. The child process will only inherit those resources necessary to run the process object's **run()** method. In particular, unnecessary file descriptors and handles from the parent process will not be inherited. Starting a process using this method is rather slow compared to using *fork*

or *forkserver*.

Available on Unix and Windows. The default on Windows and macOS.

### *fork*

The parent process uses `os.fork()` to fork the Python interpreter. The child process, when it begins, is effectively identical to the parent process. All resources of the parent are inherited by the child process. Note that safely forking a multithreaded process is problematic.

Available on Unix only. The default on Unix.

### *forkserver*

When the program starts and selects the *forkserver* start method, a server process is started. From then on, whenever a new process is needed, the parent process connects to the server and requests that it fork a new process. The fork server process is single threaded so it is safe for it to use `os.fork()`. No unnecessary resources are inherited.

Available on Unix platforms which support passing file descriptors over Unix pipes.

*Changed in version 3.8:* On macOS, the *spawn* start method is now the default. The *fork* start method should be considered unsafe as it can lead to crashes of the subprocess. See [bpo-33725](https://bugs.python.org/issue?@action=redirect&bpo=33725) [https://bugs.python.org/issue?@action=redirect&bpo=33725].

*Changed in version 3.4:* *spawn* added on all Unix platforms, and *forkserver* added for some Unix platforms. Child processes no longer inherit all of the parents inheritable handles on Windows.

On Unix using the *spawn* or *forkserver* start methods will also start a *resource tracker* process which tracks the unlinked named system

resources (such as named semaphores or `SharedMemory` objects) created by processes of the program. When all processes have exited the resource tracker unlinks any remaining tracked object. Usually there should be none, but if a process was killed by a signal there may be some “leaked” resources. (Neither leaked semaphores nor shared memory segments will be automatically unlinked until the next reboot. This is problematic for both objects because the system allows only a limited number of named semaphores, and shared memory segments occupy some space in the main memory.)

To select a start method you use the `set_start_method()` in the `if __name__ == '__main__':` clause of the main module. For example:

```
import multiprocessing as mp

def foo(q):
    q.put('hello')

if __name__ == '__main__':
    mp.set_start_method('spawn')
    q = mp.Queue()
    p = mp.Process(target=foo, args=(q,))
    p.start()
    print(q.get())
    p.join()
```

`set_start_method()` should not be used more than once in the program.

Alternatively, you can use `get_context()` to obtain a context object. Context objects have the same API as the multiprocessing module, and allow one to use multiple start methods in the same program.

```
import multiprocessing as mp

def foo(q):
    q.put('hello')
```

```

if __name__ == '__main__':
    ctx = mp.get_context('spawn')
    q = ctx.Queue()
    p = ctx.Process(target=foo, args=(q,))
    p.start()
    print(q.get())
    p.join()

```

Note that objects related to one context may not be compatible with processes for a different context. In particular, locks created using the *fork* context cannot be passed to processes started using the *spawn* or *forkserver* start methods.

A library which wants to use a particular start method should probably use `get_context()` to avoid interfering with the choice of the library user.

## Warning

The 'spawn' and 'forkserver' start methods cannot currently be used with “frozen” executables (i.e., binaries produced by packages like **PyInstaller** and **cx\_Freeze**) on Unix. The 'fork' start method does work.

## Exchanging objects between processes

**multiprocessing** supports two types of communication channel between processes:

### Queues

The `Queue` class is a near clone of `queue.Queue`. For example:

```

from multiprocessing import Process, Queue

def f(q):
    q.put([42, None, 'hello'])

```

```

if __name__ == '__main__':
    q = Queue()
    p = Process(target=f, args=(q,))
    p.start()
    print(q.get())      # prints "[42, None, 'hello']"
    p.join()

```

Queues are thread and process safe.

## Pipes

The `Pipe()` function returns a pair of connection objects connected by a pipe which by default is duplex (two-way). For example:

```

from multiprocessing import Process, Pipe

def f(conn):
    conn.send([42, None, 'hello'])
    conn.close()

if __name__ == '__main__':
    parent_conn, child_conn = Pipe()
    p = Process(target=f, args=(child_conn,))
    p.start()
    print(parent_conn.recv())  # prints "[42, None, 'hello']"
    p.join()

```

The two connection objects returned by `Pipe()` represent the two ends of the pipe. Each connection object has `send()` and `recv()` methods (among others). Note that data in a pipe may become corrupted if two processes (or threads) try to read from or write to the *same* end of the pipe at the same time. Of course there is no risk of corruption from processes using different ends of the pipe at the same time.

## Synchronization between processes

**multiprocessing** contains equivalents of all the synchronization primitives from **threading**. For instance one can use a lock to ensure that only one process prints to standard output at a time:

```
from multiprocessing import Process, Lock

def f(l, i):
    l.acquire()
    try:
        print('hello world', i)
    finally:
        l.release()

if __name__ == '__main__':
    lock = Lock()

    for num in range(10):
        Process(target=f, args=(lock, num)).start()
```

Without using the lock output from the different processes is liable to get all mixed up.

## Sharing state between processes

As mentioned above, when doing concurrent programming it is usually best to avoid using shared state as far as possible. This is particularly true when using multiple processes.

However, if you really do need to use some shared data then **multiprocessing** provides a couple of ways of doing so.

### Shared memory

Data can be stored in a shared memory map using **Value** or **Array**. For example, the following code

```
from multiprocessing import Process, Value, Array

def f(n, a):
    n.value = 3.1415927
```

```

    for i in range(len(a)):
        a[i] = -a[i]

if __name__ == '__main__':
    num = Value('d', 0.0)
    arr = Array('i', range(10))

    p = Process(target=f, args=(num, arr))
    p.start()
    p.join()

    print(num.value)
    print(arr[:])

```

will print

```

3.1415927
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]

```

The 'd' and 'i' arguments used when creating num and arr are typecodes of the kind used by the [array](#) module: 'd' indicates a double precision float and 'i' indicates a signed integer. These shared objects will be process and thread-safe.

For more flexibility in using shared memory one can use the [multiprocessing.sharedctypes](#) module which supports the creation of arbitrary ctypes objects allocated from shared memory.

## Server process

A manager object returned by [Manager\(\)](#) controls a server process which holds Python objects and allows other processes to manipulate them using proxies.

A manager returned by [Manager\(\)](#) will support types [list](#), [dict](#), [Namespace](#), [Lock](#), [RLock](#), [Semaphore](#), [BoundedSemaphore](#), [Condition](#),

**Event**, **Barrier**, **Queue**, **Value** and **Array**.

For example,

```
from multiprocessing import Process, Manager

def f(d, l):
    d[1] = '1'
    d['2'] = 2
    d[0.25] = None
    l.reverse()

if __name__ == '__main__':
    with Manager() as manager:
        d = manager.dict()
        l = manager.list(range(10))

        p = Process(target=f, args=(d, l))
        p.start()
        p.join()

        print(d)
        print(l)
```

will print

```
{0.25: None, 1: '1', '2': 2}
[9, 8, 7, 6, 5, 4, 3, 2, 1, 0]
```

Server process managers are more flexible than using shared memory objects because they can be made to support arbitrary object types. Also, a single manager can be shared by processes on different computers over a network. They are, however, slower than using shared memory.

## Using a pool of workers

The **Pool** class represents a pool of worker processes. It has methods which allows tasks to be offloaded to the worker processes in a few different ways.

For example:

```
from multiprocessing import Pool, TimeoutError
import time
import os

def f(x):
    return x*x

if __name__ == '__main__':
    # start 4 worker processes
    with Pool(processes=4) as pool:

        # print "[0, 1, 4, ..., 81]"
        print(pool.map(f, range(10)))

        # print same numbers in arbitrary order
        for i in pool.imap_unordered(f, range(10)):
            print(i)

        # evaluate "f(20)" asynchronously
        res = pool.apply_async(f, (20,))      # runs in
        print(res.get(timeout=1))             # prints "400"

        # evaluate "os.getpid()" asynchronously
        res = pool.apply_async(os.getpid, ()) # runs in
        print(res.get(timeout=1))             # prints "1"

        # launching multiple evaluations asynchronously
        multiple_results = [pool.apply_async(os.getpid,
        print([res.get(timeout=1) for res in multiple_results])

        # make a single worker sleep for 10 seconds
        res = pool.apply_async(time.sleep, (10,))
        try:
            print(res.get(timeout=1))
        except TimeoutError:
            print("We lacked patience and got a multiproc")
```

```
print("For the moment, the pool remains available")

# exiting the 'with'-block has stopped the pool
print("Now the pool is closed and no longer available")
```

Note that the methods of a pool should only ever be used by the process which created it.

## Note

Functionality within this package requires that the `__main__` module be importable by the children. This is covered in [Programming guidelines](#) however it is worth pointing out here. This means that some examples, such as the [multiprocessing.pool.Pool](#) examples will not work in the interactive interpreter. For example:

```
>>> from multiprocessing import Pool
>>> p = Pool(5)
>>> def f(x):
...     return x*x
...
>>> with p:
...     p.map(f, [1,2,3])
Process PoolWorker-1:
Process PoolWorker-2:
Process PoolWorker-3:
Traceback (most recent call last):
AttributeError: Can't get attribute 'f' on <module '__main__' from ...
AttributeError: Can't get attribute 'f' on <module '__main__' from ...
AttributeError: Can't get attribute 'f' on <module '__main__' from ...
```

(If you try this it will actually output three full tracebacks interleaved in a semi-random fashion, and then you may have to stop the parent process somehow.)

## Reference

The `multiprocessing` package mostly replicates the API of the `threading` module.

## Process and exceptions

```
class multiprocessing.Process(group=None, target=None,  
name=None, args=(), kwargs={}, *, daemon=None)
```

Process objects represent activity that is run in a separate process. The `Process` class has equivalents of all the methods of `threading.Thread`.

The constructor should always be called with keyword arguments. `group` should always be `None`; it exists solely for compatibility with `threading.Thread`. `target` is the callable object to be invoked by the `run()` method. It defaults to `None`, meaning nothing is called. `name` is the process name (see `name` for more details). `args` is the argument tuple for the target invocation. `kwargs` is a dictionary of keyword arguments for the target invocation. If provided, the keyword-only `daemon` argument sets the process `daemon` flag to `True` or `False`. If `None` (the default), this flag will be inherited from the creating process.

By default, no arguments are passed to `target`. The `args` argument, which defaults to `()`, can be used to specify a list or tuple of the arguments to pass to `target`.

If a subclass overrides the constructor, it must make sure it invokes the base class constructor (`Process.__init__()`) before doing anything else to the process.

*Changed in version 3.3:* Added the `daemon` argument.

`run()`

Method representing the process's activity.

You may override this method in a subclass. The standard `run()` method invokes the callable object passed to the object's constructor as the target argument, if any, with sequential and keyword

arguments taken from the *args* and *kwargs* arguments, respectively.

Using a list or tuple as the *args* argument passed to **Process** achieves the same effect.

Example:

```
>>> from multiprocessing import Process
>>> p = Process(target=print, args=[1])
>>> p.run()
1
>>> p = Process(target=print, args=(1,))
>>> p.run()
1
```

**start()**

Start the process's activity.

This must be called at most once per process object. It arranges for the object's **run()** method to be invoked in a separate process.

**join([*timeout*])**

If the optional argument *timeout* is `None` (the default), the method blocks until the process whose **join()** method is called terminates. If *timeout* is a positive number, it blocks at most *timeout* seconds. Note that the method returns `None` if its process terminates or if the method times out. Check the process's **exitcode** to determine if it terminated.

A process can be joined many times.

A process cannot join itself because this would cause a deadlock. It is an error to attempt to join a process before it has been started.

**name**

The process's name. The name is a string used for identification purposes only. It has no semantics. Multiple processes may be given the same name.

The initial name is set by the constructor. If no explicit name is provided to the constructor, a name of the form 'Process-N<sub>1</sub>:N<sub>2</sub>:...:N<sub>k</sub>' is constructed, where each N<sub>k</sub> is the N-th child of its parent.

`is_alive()`

Return whether the process is alive.

Roughly, a process object is alive from the moment the `start()` method returns until the child process terminates.

`daemon`

The process's daemon flag, a Boolean value. This must be set before `start()` is called.

The initial value is inherited from the creating process.

When a process exits, it attempts to terminate all of its daemon child processes.

Note that a daemon process is not allowed to create child processes. Otherwise a daemon process would leave its children orphaned if it gets terminated when its parent process exits. Additionally, these are **not** Unix daemons or services, they are normal processes that will be terminated (and not joined) if non-daemon processes have exited.

In addition to the `threading.Thread` API, `Process` objects also support the following attributes and methods:

`pid`

Return the process ID. Before the process is spawned, this will be `None`.

## exitcode

The child's exit code. This will be `None` if the process has not yet terminated.

If the child's `run()` method returned normally, the exit code will be 0. If it terminated via `sys.exit()` with an integer argument *N*, the exit code will be *N*.

If the child terminated due to an exception not caught within `run()`, the exit code will be 1. If it was terminated by signal *N*, the exit code will be the negative value *-N*.

## authkey

The process's authentication key (a byte string).

When `multiprocessing` is initialized the main process is assigned a random string using `os.urandom()`.

When a `Process` object is created, it will inherit the authentication key of its parent process, although this may be changed by setting `authkey` to another byte string.

See [Authentication keys](#).

## sentinel

A numeric handle of a system object which will become "ready" when the process ends.

You can use this value if you want to wait on several events at once using `multiprocessing.connection.wait()`. Otherwise calling `join()` is simpler.

On Windows, this is an OS handle usable with the `WaitForSingleObject` and `WaitForMultipleObjects` family of API calls. On Unix, this is a file descriptor usable with primitives

from the `select` module.

*New in version 3.3.*

## `terminate()`

Terminate the process. On Unix this is done using the `SIGTERM` signal; on Windows `TerminateProcess()` is used. Note that exit handlers and finally clauses, etc., will not be executed.

Note that descendant processes of the process will *not* be terminated – they will simply become orphaned.

### Warning

If this method is used when the associated process is using a pipe or queue then the pipe or queue is liable to become corrupted and may become unusable by other process. Similarly, if the process has acquired a lock or semaphore etc. then terminating it is liable to cause other processes to deadlock.

## `kill()`

Same as `terminate()` but using the `SIGKILL` signal on Unix.

*New in version 3.7.*

## `close()`

Close the `Process` object, releasing all resources associated with it. `ValueError` is raised if the underlying process is still running. Once `close()` returns successfully, most other methods and attributes of the `Process` object will raise `ValueError`.

*New in version 3.7.*

Note that the `start()`, `join()`, `is_alive()`, `terminate()` and `exitcode` methods should only be called by the process that created the process object.

Example usage of some of the methods of `Process`:

```
>>> import multiprocessing, time, signal
>>> p = multiprocessing.Process(target=time.sleep,
>>> print(p, p.is_alive())
<Process ... initial> False
>>> p.start()
>>> print(p, p.is_alive())
<Process ... started> True
>>> p.terminate()
>>> time.sleep(0.1)
>>> print(p, p.is_alive())
<Process ... stopped exitcode=-SIGTERM> False
>>> p.exitcode == -signal.SIGTERM
True
```

*exception* `multiprocessing.ProcessError`

The base class of all `multiprocessing` exceptions.

*exception* `multiprocessing.BufferTooShort`

Exception raised by `Connection.recv_bytes_into()` when the supplied buffer object is too small for the message read.

If `e` is an instance of `BufferTooShort` then `e.args[0]` will give the message as a byte string.

*exception* `multiprocessing.AuthenticationError`

Raised when there is an authentication error.

*exception* `multiprocessing.TimeoutError`

Raised by methods with a timeout when the timeout expires.

## Pipes and Queues

When using multiple processes, one generally uses message passing for communication between processes and avoids having to use any synchronization primitives like locks.

For passing messages one can use `Pipe()` (for a connection between two processes) or a queue (which allows multiple producers and consumers).

The `Queue`, `SimpleQueue` and `JoinableQueue` types are multi-producer, multi-consumer FIFO queues modelled on the `queue.Queue` class in the standard library. They differ in that `Queue` lacks the `task_done()` and `join()` methods introduced into Python 2.5's `queue.Queue` class.

If you use `JoinableQueue` then you **must** call `JoinableQueue.task_done()` for each task removed from the queue or else the semaphore used to count the number of unfinished tasks may eventually overflow, raising an exception.

Note that one can also create a shared queue by using a manager object – see [Managers](#).

### Note

`multiprocessing` uses the usual `queue.Empty` and `queue.Full` exceptions to signal a timeout. They are not available in the `multiprocessing` namespace so you need to import them from `queue`.

### Note

When an object is put on a queue, the object is pickled and a background thread later flushes the pickled data to an underlying pipe. This has some consequences which are a little surprising, but should not cause any practical difficulties – if they really bother you then you can instead use a queue created with a [manager](#).

1. After putting an object on an empty queue there may be an infinitesimal delay before the queue's `empty()` method

- returns `False` and `get_nowait()` can return without raising `queue.Empty`.
2. If multiple processes are enqueueing objects, it is possible for the objects to be received at the other end out-of-order. However, objects enqueued by the same process will always be in the expected order with respect to each other.

## Warning

If a process is killed using `Process.terminate()` or `os.kill()` while it is trying to use a `Queue`, then the data in the queue is likely to become corrupted. This may cause any other process to get an exception when it tries to use the queue later on.

## Warning

As mentioned above, if a child process has put items on a queue (and it has not used `JoinableQueue.cancel_join_thread`), then that process will not terminate until all buffered items have been flushed to the pipe.

This means that if you try joining that process you may get a deadlock unless you are sure that all items which have been put on the queue have been consumed. Similarly, if the child process is non-daemonic then the parent process may hang on exit when it tries to join all its non-daemonic children.

Note that a queue created using a manager does not have this issue. See [Programming guidelines](#).

For an example of the usage of queues for interprocess communication see [Examples](#).

`multiprocessing.Pipe([duplex])`

Returns a pair (`conn1`, `conn2`) of `Connection` objects representing the ends of a pipe.

If *duplex* is `True` (the default) then the pipe is bidirectional. If *duplex* is `False` then the pipe is unidirectional: `conn1` can only be used for receiving messages and `conn2` can only be used for sending messages.

*class multiprocessing.Queue([maxsize])*

Returns a process shared queue implemented using a pipe and a few locks/semaphores. When a process first puts an item on the queue a feeder thread is started which transfers objects from a buffer into the pipe.

The usual `queue.Empty` and `queue.Full` exceptions from the standard library's `queue` module are raised to signal timeouts.

`Queue` implements all the methods of `queue.Queue` except for `task_done()` and `join()`.

*qsize()*

Return the approximate size of the queue. Because of multithreading/multiprocessing semantics, this number is not reliable.

Note that this may raise `NotImplementedError` on Unix platforms like macOS where `sem_getvalue()` is not implemented.

*empty()*

Return `True` if the queue is empty, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

*full()*

Return `True` if the queue is full, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

*put(obj[, block[, timeout]])*

Put `obj` into the queue. If the optional argument `block` is `True` (the default) and `timeout` is `None` (the default), block if necessary until a free slot is available. If `timeout` is a positive number, it blocks at most `timeout` seconds and raises the `queue.Full` exception if no free slot was available within that time. Otherwise (`block` is `False`), put an item on the queue if a free slot is immediately available, else raise the `queue.Full` exception (`timeout` is ignored in that case).

*Changed in version 3.8:* If the queue is closed, `ValueError` is raised instead of `AssertionError`.

`put_nowait(obj)`

Equivalent to `put(obj, False)`.

`get([block[, timeout]])`

Remove and return an item from the queue. If optional args `block` is `True` (the default) and `timeout` is `None` (the default), block if necessary until an item is available. If `timeout` is a positive number, it blocks at most `timeout` seconds and raises the `queue.Empty` exception if no item was available within that time. Otherwise (`block` is `False`), return an item if one is immediately available, else raise the `queue.Empty` exception (`timeout` is ignored in that case).

*Changed in version 3.8:* If the queue is closed, `ValueError` is raised instead of `OSError`.

`get_nowait()`

Equivalent to `get(False)`.

`multiprocessing.Queue` has a few additional methods not found in `queue.Queue`. These methods are usually unnecessary for most code:

`close()`

Indicate that no more data will be put on this queue by the current process. The background thread will quit once it has flushed all buffered data to the pipe. This is called automatically when the queue is garbage collected.

### `join_thread()`

Join the background thread. This can only be used after `close()` has been called. It blocks until the background thread exits, ensuring that all data in the buffer has been flushed to the pipe.

By default if a process is not the creator of the queue then on exit it will attempt to join the queue's background thread. The process can call `cancel_join_thread()` to make `join_thread()` do nothing.

### `cancel_join_thread()`

Prevent `join_thread()` from blocking. In particular, this prevents the background thread from being joined automatically when the process exits – see `join_thread()`.

A better name for this method might be `allow_exit_without_flush()`. It is likely to cause enqueued data to be lost, and you almost certainly will not need to use it. It is really only there if you need the current process to exit immediately without waiting to flush enqueued data to the underlying pipe, and you don't care about lost data.

## **Note**

This class's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the functionality in this class will be disabled, and attempts to instantiate a `Queue` will result in an `ImportError`. See [bpo-3770](https://bugs.python.org/bug?report=3770) [https://bugs.python.org/

issue?@action=redirect&bpo=3770] for additional information.  
The same holds true for any of the specialized queue types listed below.

*class multiprocessing.SimpleQueue*

It is a simplified **Queue** type, very close to a locked **Pipe**.

**close()**

Close the queue: release internal resources.

A queue must not be used anymore after it is closed.  
For example, **get()**, **put()** and **empty()** methods must no longer be called.

*New in version 3.9.*

**empty()**

Return **True** if the queue is empty, **False** otherwise.

**get()**

Remove and return an item from the queue.

**put(item)**

Put *item* into the queue.

*class multiprocessing.JoinableQueue([maxsize])*

**JoinableQueue**, a **Queue** subclass, is a queue which additionally has **task\_done()** and **join()** methods.

**task\_done()**

Indicate that a formerly enqueued task is complete.  
Used by queue consumers. For each **get()** used to fetch a task, a subsequent call to **task\_done()** tells the queue that the processing on the task is complete.

If a **join()** is currently blocking, it will resume when

all items have been processed (meaning that a `task_done()` call was received for every item that had been `put()` into the queue).

Raises a `ValueError` if called more times than there were items placed in the queue.

`join()`

Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer calls `task_done()` to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, `join()` unblocks.

## Miscellaneous

`multiprocessing.active_children()`

Return list of all live children of the current process.

Calling this has the side effect of “joining” any processes which have already finished.

`multiprocessing.cpu_count()`

Return the number of CPUs in the system.

This number is not equivalent to the number of CPUs the current process can use. The number of usable CPUs can be obtained with `len(os.sched_getaffinity(0))`

When the number of CPUs cannot be determined a `NotImplementedError` is raised.

**See also**

`os.cpu_count()`

`multiprocessing.current_process()`

Return the **Process** object corresponding to the current process.

An analogue of `threading.current_thread()`.

`multiprocessing.parent_process()`

Return the **Process** object corresponding to the parent process of the `current_process()`. For the main process, `parent_process` will be `None`.

*New in version 3.8.*

`multiprocessing.freeze_support()`

Add support for when a program which uses **multiprocessing** has been frozen to produce a Windows executable. (Has been tested with **py2exe**, **PyInstaller** and **cx\_Freeze**.)

One needs to call this function straight after the `if __name__ == '__main__':` line of the main module. For example:

```
from multiprocessing import Process, freeze_support

def f():
    print('hello world!')

if __name__ == '__main__':
    freeze_support()
    Process(target=f).start()
```

If the `freeze_support()` line is omitted then trying to run the frozen executable will raise **RuntimeError**.

Calling `freeze_support()` has no effect when invoked on any operating system other than Windows. In addition, if the module is being run normally by the Python interpreter on

Windows (the program has not been frozen), then `freeze_support()` has no effect.

### `multiprocessing.get_all_start_methods()`

Returns a list of the supported start methods, the first of which is the default. The possible start methods are `'fork'`, `'spawn'` and `'forkserver'`. On Windows only `'spawn'` is available. On Unix `'fork'` and `'spawn'` are always supported, with `'fork'` being the default.

*New in version 3.4.*

### `multiprocessing.get_context(method=None)`

Return a context object which has the same attributes as the `multiprocessing` module.

If `method` is `None` then the default context is returned. Otherwise `method` should be `'fork'`, `'spawn'`, `'forkserver'`. `ValueError` is raised if the specified start method is not available.

*New in version 3.4.*

### `multiprocessing.get_start_method(allow_none=False)`

Return the name of start method used for starting processes.

If the start method has not been fixed and `allow_none` is false, then the start method is fixed to the default and the name is returned. If the start method has not been fixed and `allow_none` is true then `None` is returned.

The return value can be `'fork'`, `'spawn'`, `'forkserver'` or `None`. `'fork'` is the default on Unix, while `'spawn'` is the default on Windows and macOS.

*Changed in version 3.8:* On macOS, the `spawn` start method is now the default. The `fork` start method should be considered unsafe as it can lead to crashes of the subprocess. See [bpo-33725](https://bugs.python.org/issue?@action=redirect&bpo=33725) [https://bugs.python.org/issue?@action=redirect&bpo=33725].

*New in version 3.4.*

`multiprocessing.set_executable(executable)`

Set the path of the Python interpreter to use when starting a child process. (By default `sys.executable` is used). Embedders will probably need to do some thing like

```
set_executable(os.path.join(sys.exec_prefix, 'python'))
```

before they can create child processes.

*Changed in version 3.4:* Now supported on Unix when the 'spawn' start method is used.

*Changed in version 3.11:* Accepts a [path-like object](#).

`multiprocessing.set_start_method(method, force=False)`

Set the method which should be used to start child processes. The *method* argument can be 'fork', 'spawn' or 'forkserver'. Raises `RuntimeError` if the start method has already been set and *force* is not True. If *method* is None and *force* is True then the start method is set to None. If *method* is None and *force* is False then the context is set to the default context.

Note that this should be called at most once, and it should be protected inside the `if __name__ == '__main__':` clause of the main module.

*New in version 3.4.*

## Note

`multiprocessing` contains no analogues of `threading.active_count()`, `threading.enumerate()`, `threading.settrace()`, `threading.setprofile()`, `threading.Timer`, or `threading.local`.

## Connection Objects

Connection objects allow the sending and receiving of picklable objects or strings. They can be thought of as message oriented connected sockets.

Connection objects are usually created using [Pipe](#) – see also [Listeners and Clients](#).

*class multiprocessing.connection.Connection*

*send(obj)*

Send an object to the other end of the connection which should be read using [recv\(\)](#).

The object must be picklable. Very large pickles (approximately 32 MiB + , though it depends on the OS) may raise a [ValueError](#) exception.

*recv()*

Return an object sent from the other end of the connection using [send\(\)](#). Blocks until there is something to receive. Raises [EOFError](#) if there is nothing left to receive and the other end was closed.

*fileno()*

Return the file descriptor or handle used by the connection.

*close()*

Close the connection.

This is called automatically when the connection is garbage collected.

*poll([timeout])*

Return whether there is any data available to be read.

If *timeout* is not specified then it will return immediately. If *timeout* is a number then this specifies

the maximum time in seconds to block. If *timeout* is `None` then an infinite timeout is used.

Note that multiple connection objects may be polled at once by using `multiprocessing.connection.wait()`.

`send_bytes(buffer[, offset[, size]])`

Send byte data from a [bytes-like object](#) as a complete message.

If *offset* is given then data is read from that position in *buffer*. If *size* is given then that many bytes will be read from *buffer*. Very large buffers (approximately 32 MiB +, though it depends on the OS) may raise a [ValueError](#) exception

`recv_bytes([maxlength])`

Return a complete message of byte data sent from the other end of the connection as a string. Blocks until there is something to receive. Raises [EOFError](#) if there is nothing left to receive and the other end has closed.

If *maxlength* is specified and the message is longer than *maxlength* then [OSError](#) is raised and the connection will no longer be readable.

*Changed in version 3.3:* This function used to raise [IOError](#), which is now an alias of [OSError](#).

`recv_bytes_into(buffer[, offset])`

Read into *buffer* a complete message of byte data sent from the other end of the connection and return the number of bytes in the message. Blocks until there is something to receive. Raises [EOFError](#) if there is nothing left to receive and the other end was closed.

*buffer* must be a writable [bytes-like object](#). If *offset* is

given then the message will be written into the buffer from that position. Offset must be a non-negative integer less than the length of *buffer* (in bytes).

If the buffer is too short then a **BufferTooShort** exception is raised and the complete message is available as `e.args[0]` where `e` is the exception instance.

*Changed in version 3.3:* Connection objects themselves can now be transferred between processes using `Connection.send()` and `Connection.recv()`.

*New in version 3.3:* Connection objects now support the context management protocol – see [Context Manager Types](#). `__enter__()` returns the connection object, and `__exit__()` calls `close()`.

For example:

```
>>> from multiprocessing import Pipe
>>> a, b = Pipe()
>>> a.send([1, 'hello', None])
>>> b.recv()
[1, 'hello', None]
>>> b.send_bytes(b'thank you')
>>> a.recv_bytes()
b'thank you'
>>> import array
>>> arr1 = array.array('i', range(5))
>>> arr2 = array.array('i', [0] * 10)
>>> a.send_bytes(arr1)
>>> count = b.recv_bytes_into(arr2)
>>> assert count == len(arr1) * arr1.itemsize
>>> arr2
array('i', [0, 1, 2, 3, 4, 0, 0, 0, 0, 0])
```

## Warning

The `Connection.recv()` method automatically unpickles the data it receives, which can be a security risk unless you can trust the process which sent the message.

Therefore, unless the connection object was produced using `Pipe()` you should only use the `recv()` and `send()` methods after performing some sort of authentication. See [Authentication keys](#).

## Warning

If a process is killed while it is trying to read or write to a pipe then the data in the pipe is likely to become corrupted, because it may become impossible to be sure where the message boundaries lie.

## Synchronization primitives

Generally synchronization primitives are not as necessary in a multiprocess program as they are in a multithreaded program. See the documentation for [threading](#) module.

Note that one can also create synchronization primitives by using a manager object – see [Managers](#).

```
class multiprocessing.Barrier(parties[, action[, timeout]])
```

A barrier object: a clone of [threading.Barrier](#).

*New in version 3.3.*

```
class multiprocessing.BoundedSemaphore(value)
```

A bounded semaphore object: a close analog of [threading.BoundedSemaphore](#).

A solitary difference from its close analog exists: its `acquire` method's first argument is named *block*, as is consistent with [Lock.acquire\(\)](#).

## Note

On macOS, this is indistinguishable from `Semaphore` because `sem_getvalue()` is not implemented on that platform.

`class multiprocessing.Condition([lock])`

A condition variable: an alias for `threading.Condition`.

If `lock` is specified then it should be a `Lock` or `RLock` object from `multiprocessing`.

*Changed in version 3.3:* The `wait_for()` method was added.

`class multiprocessing.Event`

A clone of `threading.Event`.

`class multiprocessing.Lock`

A non-recursive lock object: a close analog of `threading.Lock`. Once a process or thread has acquired a lock, subsequent attempts to acquire it from any process or thread will block until it is released; any process or thread may release it. The concepts and behaviors of `threading.Lock` as it applies to threads are replicated here in `multiprocessing.Lock` as it applies to either processes or threads, except as noted.

Note that `Lock` is actually a factory function which returns an instance of `multiprocessing.synchronize.Lock` initialized with a default context.

`Lock` supports the `context manager` protocol and thus may be used in `with` statements.

`acquire(block=True, timeout=None)`

Acquire a lock, blocking or non-blocking.

With the `block` argument set to `True` (the default), the

method call will block until the lock is in an unlocked state, then set it to locked and return `True`. Note that the name of this first argument differs from that in `threading.Lock.acquire()`.

With the *block* argument set to `False`, the method call does not block. If the lock is currently in a locked state, return `False`; otherwise set the lock to a locked state and return `True`.

When invoked with a positive, floating-point value for *timeout*, block for at most the number of seconds specified by *timeout* as long as the lock can not be acquired. Invocations with a negative value for *timeout* are equivalent to a *timeout* of zero. Invocations with a *timeout* value of `None` (the default) set the timeout period to infinite. Note that the treatment of negative or `None` values for *timeout* differs from the implemented behavior in `threading.Lock.acquire()`. The *timeout* argument has no practical implications if the *block* argument is set to `False` and is thus ignored. Returns `True` if the lock has been acquired or `False` if the timeout period has elapsed.

## `release()`

Release a lock. This can be called from any process or thread, not only the process or thread which originally acquired the lock.

Behavior is the same as in `threading.Lock.release()` except that when invoked on an unlocked lock, a `ValueError` is raised.

## `class multiprocessing.RLock`

A recursive lock object: a close analog of `threading.RLock`. A recursive lock must be released by the process or thread that acquired it. Once a process or thread has acquired a recursive lock, the same process or thread may acquire it again without blocking; that process or thread must

release it once for each time it has been acquired.

Note that `RLock` is actually a factory function which returns an instance of `multiprocessing.synchronize.RLock` initialized with a default context.

`RLock` supports the `context manager` protocol and thus may be used in `with` statements.

`acquire(block=True, timeout=None)`

Acquire a lock, blocking or non-blocking.

When invoked with the *block* argument set to `True`, block until the lock is in an unlocked state (not owned by any process or thread) unless the lock is already owned by the current process or thread. The current process or thread then takes ownership of the lock (if it does not already have ownership) and the recursion level inside the lock increments by one, resulting in a return value of `True`. Note that there are several differences in this first argument's behavior compared to the implementation of `threading.RLock.acquire()`, starting with the name of the argument itself.

When invoked with the *block* argument set to `False`, do not block. If the lock has already been acquired (and thus is owned) by another process or thread, the current process or thread does not take ownership and the recursion level within the lock is not changed, resulting in a return value of `False`. If the lock is in an unlocked state, the current process or thread takes ownership and the recursion level is incremented, resulting in a return value of `True`.

Use and behaviors of the *timeout* argument are the same as in `Lock.acquire()`. Note that some of these behaviors of *timeout* differ from the implemented behaviors in `threading.RLock.acquire()`.

`release()`

Release a lock, decrementing the recursion level. If after the decrement the recursion level is zero, reset the lock to unlocked (not owned by any process or thread) and if any other processes or threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling process or thread.

Only call this method when the calling process or thread owns the lock. An `AssertionError` is raised if this method is called by a process or thread other than the owner or if the lock is in an unlocked (unowned) state. Note that the type of exception raised in this situation differs from the implemented behavior in `threading.RLock.release()`.

`class multiprocessing.Semaphore([value])`

A semaphore object: a close analog of `threading.Semaphore`.

A solitary difference from its close analog exists: its `acquire` method's first argument is named `block`, as is consistent with `Lock.acquire()`.

## Note

On macOS, `sem_timedwait` is unsupported, so calling `acquire()` with a timeout will emulate that function's behavior using a sleeping loop.

## Note

If the SIGINT signal generated by Ctrl-C arrives while the main thread is blocked by a call to `BoundedSemaphore.acquire()`, `Lock.acquire()`, `RLock.acquire()`, `Semaphore.acquire()`,

`Condition.acquire()` or `Condition.wait()` then the call will be immediately interrupted and `KeyboardInterrupt` will be raised.

This differs from the behaviour of `threading` where `SIGINT` will be ignored while the equivalent blocking calls are in progress.

## Note

Some of this package's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the `multiprocessing.synchronize` module will be disabled, and attempts to import it will result in an `ImportError`. See [bpo-3770](https://bugs.python.org/issue?@action=redirect&bpo=3770) [https://bugs.python.org/issue?@action=redirect&bpo=3770] for additional information.

## Shared `ctypes` Objects

It is possible to create shared objects using shared memory which can be inherited by child processes.

`multiprocessing.Value(typecode_or_type, *args, lock = True)`

Return a `ctypes` object allocated from shared memory. By default the return value is actually a synchronized wrapper for the object. The object itself can be accessed via the `value` attribute of a `Value`.

`typecode_or_type` determines the type of the returned object: it is either a `ctypes` type or a one character typecode of the kind used by the `array` module. `*args` is passed on to the constructor for the type.

If `lock` is `True` (the default) then a new recursive lock object is created to synchronize access to the value. If `lock` is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If `lock` is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Operations like `+=` which involve a read and write are not atomic. So if, for instance, you want to atomically increment a shared value it is insufficient to just do

```
counter.value += 1
```

Assuming the associated lock is recursive (which it is by default) you can instead do

```
with counter.get_lock():  
    counter.value += 1
```

Note that *lock* is a keyword-only argument.

`multiprocessing.Array(typecode_or_type, size_or_initializer, *,  
lock=True)`

Return a ctypes array allocated from shared memory. By default the return value is actually a synchronized wrapper for the array.

*typecode\_or\_type* determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the `array` module. If *size\_or\_initializer* is an integer, then it determines the length of the array, and the array will be initially zeroed. Otherwise, *size\_or\_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that *lock* is a keyword only argument.

Note that an array of `ctypes.c_char` has *value* and *raw* attributes which allow one to use it to store and retrieve strings.

## The `multiprocessing.sharedctypes` module

The `multiprocessing.sharedctypes` module provides functions for allocating `ctypes` objects from shared memory which can be inherited by child processes.

### Note

Although it is possible to store a pointer in shared memory remember that this will refer to a location in the address space of a specific process. However, the pointer is quite likely to be invalid in the context of a second process and trying to dereference the pointer from the second process may cause a crash.

`multiprocessing.sharedctypes.RawArray(typecode_or_type, size_or_initializer)`

Return a ctypes array allocated from shared memory.

*typecode\_or\_type* determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the `array` module. If *size\_or\_initializer* is an integer then it determines the length of the array, and the array will be initially zeroed. Otherwise *size\_or\_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

Note that setting and getting an element is potentially non-atomic – use `Array()` instead to make sure that access is automatically synchronized using a lock.

`multiprocessing.sharedctypes.RawValue(typecode_or_type, *args)`

Return a ctypes object allocated from shared memory.

*typecode\_or\_type* determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the `array` module. *\*args* is passed on to the constructor for the type.

Note that setting and getting the value is potentially non-atomic – use `Value()` instead to make sure that access is automatically synchronized using a lock.

Note that an array of `ctypes.c_char` has `value` and `raw` attributes which allow one to use it to store and retrieve strings – see documentation for `ctypes`.

```
multiprocessing.sharedctypes.Array(typecode_or_type,  
size_or_initializer, *, lock = True)
```

The same as `RawArray()` except that depending on the value of `lock` a process-safe synchronization wrapper may be returned instead of a raw ctypes array.

If `lock` is `True` (the default) then a new lock object is created to synchronize access to the value. If `lock` is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If `lock` is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that `lock` is a keyword-only argument.

```
multiprocessing.sharedctypes.Value(typecode_or_type, *args,  
lock = True)
```

The same as `RawValue()` except that depending on the value of `lock` a process-safe synchronization wrapper may be returned instead of a raw ctypes object.

If `lock` is `True` (the default) then a new lock object is created to synchronize access to the value. If `lock` is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If `lock` is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that `lock` is a keyword-only argument.

```
multiprocessing.sharedctypes.copy(obj)
```

Return a ctypes object allocated from shared memory which is a copy of the ctypes object *obj*.

`multiprocessing.sharedctypes.synchronized(obj[, lock])`

Return a process-safe wrapper object for a ctypes object which uses *lock* to synchronize access. If *lock* is `None` (the default) then a `multiprocessing.RLock` object is created automatically.

A synchronized wrapper will have two methods in addition to those of the object it wraps: `get_obj()` returns the wrapped object and `get_lock()` returns the lock object used for synchronization.

Note that accessing the ctypes object through the wrapper can be a lot slower than accessing the raw ctypes object.

*Changed in version 3.5:* Synchronized objects support the `context manager` protocol.

The table below compares the syntax for creating shared ctypes objects from shared memory with the normal ctypes syntax. (In the table `MyStruct` is some subclass of `ctypes.Structure`.)

#### sharedctypes using typecode

---

|                                    |
|------------------------------------|
| <code>RawValue(2, 'd', 0.1)</code> |
|------------------------------------|

---

|                                          |
|------------------------------------------|
| <code>MyStruct(4, MyStruct, 4, 6)</code> |
|------------------------------------------|

---

|                                  |
|----------------------------------|
| <code>RawArray(7, 'h', 7)</code> |
|----------------------------------|

---

|                                            |
|--------------------------------------------|
| <code>RawArray(8, 'i', 1989, 2, 8))</code> |
|--------------------------------------------|

---

Below is an example where a number of ctypes objects are modified by a child process:

```
from multiprocessing import Process, Lock
from multiprocessing.sharedctypes import Value, Array
from ctypes import Structure, c_double

class Point(Structure):
    _fields_ = [('x', c_double), ('y', c_double)]
```

```

def modify(n, x, s, A):
    n.value **= 2
    x.value **= 2
    s.value = s.value.upper()
    for a in A:
        a.x **= 2
        a.y **= 2

if __name__ == '__main__':
    lock = Lock()

    n = Value('i', 7)
    x = Value(c_double, 1.0/3.0, lock=False)
    s = Array('c', b'hello world', lock=lock)
    A = Array(Point, [(1.875,-6.25), (-5.75,2.0), (2.375,
    4.0)], lock=lock)

    p = Process(target=modify, args=(n, x, s, A))
    p.start()
    p.join()

    print(n.value)
    print(x.value)
    print(s.value)
    print([(a.x, a.y) for a in A])

```

The results printed are

```

49
0.11111111111111111
HELLO WORLD
[(3.515625, 39.0625), (33.0625, 4.0), (5.640625, 90.25)]

```

## Managers

Managers provide a way to create data which can be shared between different processes, including sharing over a network between processes running on different machines. A manager object controls a server process which manages *shared objects*. Other processes can access the shared objects by using proxies.

`multiprocessing.Manager()`

Returns a started `SyncManager` object which can be used for sharing objects between processes. The returned manager object corresponds to a spawned child process and has methods which will create shared objects and return corresponding proxies.

Manager processes will be shutdown as soon as they are garbage collected or their parent process exits. The manager classes are defined in the `multiprocessing.managers` module:

```
class multiprocessing.managers.BaseManager(address=None,
authkey=None, serializer='pickle', ctx=None, *,
shutdown_timeout=1.0)
```

Create a `BaseManager` object.

Once created one should call `start()` or `get_server().serve_forever()` to ensure that the manager object refers to a started manager process.

`address` is the address on which the manager process listens for new connections. If `address` is `None` then an arbitrary one is chosen.

`authkey` is the authentication key which will be used to check the validity of incoming connections to the server process. If `authkey` is `None` then `current_process().authkey` is used. Otherwise `authkey` is used and it must be a byte string.

`serializer` must be `'pickle'` (use `pickle` serialization) or `'xmlrpclib'` (use `xmlrpc.client` serialization).

`ctx` is a context object, or `None` (use the current context). See the `get_context()` function.

`shutdown_timeout` is a timeout in seconds used to wait until the process used by the manager completes in the `shutdown()` method. If the shutdown times out, the process is terminated. If terminating the process also times out, the process is killed.

*Changed in version 3.11:* Added the *shutdown\_timeout* parameter.

`start([initializer[, initargs]])`

Start a subprocess to start the manager. If *initializer* is not `None` then the subprocess will call `initializer(*initargs)` when it starts.

`get_server()`

Returns a **Server** object which represents the actual server under the control of the Manager. The **Server** object supports the **`serve_forever()`** method:

```
>>> from multiprocessing.managers import BaseManager
>>> manager = BaseManager(address=('', 50000),
>>> server = manager.get_server()
>>> server.serve_forever()
```

**Server** additionally has an **`address`** attribute.

`connect()`

Connect a local manager object to a remote manager process:

```
>>> from multiprocessing.managers import BaseManager
>>> m = BaseManager(address=('127.0.0.1', 50000))
>>> m.connect()
```

`shutdown()`

Stop the process used by the manager. This is only available if **`start()`** has been used to start the server process.

This can be called multiple times.

`register(typeid[, callable[, proxytype[, exposed[,  
method_to_typeid[, create_method]]]]])`

A classmethod which can be used for registering a type or callable with the manager class.

*typeid* is a “type identifier” which is used to identify a particular type of shared object. This must be a string.

*callable* is a callable used for creating objects for this type identifier. If a manager instance will be connected to the server using the `connect()` method, or if the *create\_method* argument is `False` then this can be left as `None`.

*proxytype* is a subclass of `BaseProxy` which is used to create proxies for shared objects with this *typeid*. If `None` then a proxy class is created automatically.

*exposed* is used to specify a sequence of method names which proxies for this typeid should be allowed to access using `BaseProxy._callmethod()`. (If *exposed* is `None` then `proxytype._exposed_` is used instead if it exists.) In the case where no exposed list is specified, all “public methods” of the shared object will be accessible. (Here a “public method” means any attribute which has a `__call__()` method and whose name does not begin with `'_'`.)

*method\_to\_typeid* is a mapping used to specify the return type of those exposed methods which should return a proxy. It maps method names to typeid strings. (If *method\_to\_typeid* is `None` then `proxytype._method_to_typeid_` is used instead if it exists.) If a method’s name is not a key of this mapping or if the mapping is `None` then the object returned by the method will be copied by value.

*create\_method* determines whether a method should be created with name *typeid* which can be used to tell the server process to create a new shared object and return a proxy for it. By default it is `True`.

`BaseManager` instances also have one read-only property:

address

The address used by the manager.

*Changed in version 3.3:* Manager objects support the context management protocol – see [Context Manager Types](#).

`__enter__()` starts the server process (if it has not already started) and then returns the manager object. `__exit__()` calls `shutdown()`.

In previous versions `__enter__()` did not start the manager's server process if it was not already started.

*class* multiprocessing.managers.SyncManager

A subclass of [BaseManager](#) which can be used for the synchronization of processes. Objects of this type are returned by `multiprocessing.Manager()`.

Its methods create and return [Proxy Objects](#) for a number of commonly used data types to be synchronized across processes. This notably includes shared lists and dictionaries.

`Barrier(parties[, action[, timeout]])`

Create a shared [threading.Barrier](#) object and return a proxy for it.

*New in version 3.3.*

`BoundedSemaphore([value])`

Create a shared [threading.BoundedSemaphore](#) object and return a proxy for it.

`Condition([lock])`

Create a shared [threading.Condition](#) object and return a proxy for it.

If *lock* is supplied then it should be a proxy for a [threading.Lock](#) or [threading.RLock](#) object.

*Changed in version 3.3:* The `wait_for()` method was added.

`Event()`

Create a shared `threading.Event` object and return a proxy for it.

`Lock()`

Create a shared `threading.Lock` object and return a proxy for it.

`Namespace()`

Create a shared `Namespace` object and return a proxy for it.

`Queue([maxsize])`

Create a shared `queue.Queue` object and return a proxy for it.

`RLock()`

Create a shared `threading.RLock` object and return a proxy for it.

`Semaphore([value])`

Create a shared `threading.Semaphore` object and return a proxy for it.

`Array(typecode, sequence)`

Create an array and return a proxy for it.

`Value(typecode, value)`

Create an object with a writable `value` attribute and return a proxy for it.

`dict()`

`dict(mapping)`

`dict(sequence)`

Create a shared **dict** object and return a proxy for it.

`list()`

`list(sequence)`

Create a shared **list** object and return a proxy for it.

*Changed in version 3.6:* Shared objects are capable of being nested. For example, a shared container object such as a shared list can contain other shared objects which will all be managed and synchronized by the **SyncManager**.

*class* multiprocessing.managers.Namespace

A type that can register with **SyncManager**.

A namespace object has no public methods, but does have writable attributes. Its representation shows the values of its attributes.

However, when using a proxy for a namespace object, an attribute beginning with `'_'` will be an attribute of the proxy and not an attribute of the referent:

```
>>> manager = multiprocessing.Manager()
>>> Global = manager.Namespace()
>>> Global.x = 10
>>> Global.y = 'hello'
>>> Global._z = 12.3      # this is an attribute of the proxy
>>> print(Global)
Namespace(x=10, y='hello')
```

## Customized managers

To create one's own manager, one creates a subclass of **BaseManager** and uses the **register()** classmethod to register new types or callables with the manager class. For example:

```

from multiprocessing.managers import BaseManager

class MathsClass:
    def add(self, x, y):
        return x + y
    def mul(self, x, y):
        return x * y

class MyManager(BaseManager):
    pass

MyManager.register('Maths', MathsClass)

if __name__ == '__main__':
    with MyManager() as manager:
        maths = manager.Maths()
        print(maths.add(4, 3))           # prints 7
        print(maths.mul(7, 8))          # prints 56

```

## Using a remote manager

It is possible to run a manager server on one machine and have clients use it from other machines (assuming that the firewalls involved allow it).

Running the following commands creates a server for a single shared queue which remote clients can access:

```

>>> from multiprocessing.managers import BaseManager
>>> from queue import Queue
>>> queue = Queue()
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=('', 50000), authkey=b'abra')
>>> s = m.get_server()
>>> s.serve_forever()

```

One client can access the server as follows:

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey=b'abc123')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.put('hello')
```

Another client can also use it:

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey=b'abc123')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.get()
'hello'
```

Local processes can also access that queue, using the code from above on the client to access it remotely:

```
>>> from multiprocessing import Process, Queue
>>> from multiprocessing.managers import BaseManager
>>> class Worker(Process):
...     def __init__(self, q):
...         self.q = q
...         super().__init__()
...     def run(self):
...         self.q.put('local hello')
...
>>> queue = Queue()
>>> w = Worker(queue)
>>> w.start()
>>> class QueueManager(BaseManager): pass
...
>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey=b'abc123')
>>> s = m.get_server()
```

```
>>> s.serve_forever()
```

## Proxy Objects

A proxy is an object which *refers* to a shared object which lives (presumably) in a different process. The shared object is said to be the *referent* of the proxy. Multiple proxy objects may have the same referent.

A proxy object has methods which invoke corresponding methods of its referent (although not every method of the referent will necessarily be available through the proxy). In this way, a proxy can be used just like its referent can:

```
>>> from multiprocessing import Manager
>>> manager = Manager()
>>> l = manager.list([i*i for i in range(10)])
>>> print(l)
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
>>> print(repr(l))
<ListProxy object, typeid 'list' at 0x...>
>>> l[4]
16
>>> l[2:5]
[4, 9, 16]
```

Notice that applying `str()` to a proxy will return the representation of the referent, whereas applying `repr()` will return the representation of the proxy.

An important feature of proxy objects is that they are picklable so they can be passed between processes. As such, a referent can contain [Proxy Objects](#). This permits nesting of these managed lists, dicts, and other [Proxy Objects](#):

```
>>> a = manager.list()
>>> b = manager.list()
>>> a.append(b)           # referent of a now contains ref
>>> print(a, b)
[<ListProxy object, typeid 'list' at ...>] []
```

```
>>> b.append('hello')
>>> print(a[0], b)
['hello'] ['hello']
```

Similarly, dict and list proxies may be nested inside one another:

```
>>> l_outer = manager.list([ manager.dict() for i in range(2)])
>>> d_first_inner = l_outer[0]
>>> d_first_inner['a'] = 1
>>> d_first_inner['b'] = 2
>>> l_outer[1]['c'] = 3
>>> l_outer[1]['z'] = 26
>>> print(l_outer[0])
{'a': 1, 'b': 2}
>>> print(l_outer[1])
{'c': 3, 'z': 26}
```

If standard (non-proxy) **list** or **dict** objects are contained in a referent, modifications to those mutable values will not be propagated through the manager because the proxy has no way of knowing when the values contained within are modified. However, storing a value in a container proxy (which triggers a `__setitem__` on the proxy object) does propagate through the manager and so to effectively modify such an item, one could re-assign the modified value to the container proxy:

```
# create a list proxy and append a mutable object (a dict)
lproxy = manager.list()
lproxy.append({})
# now mutate the dictionary
d = lproxy[0]
d['a'] = 1
d['b'] = 2
# at this point, the changes to d are not yet synced, but
# updating the dictionary, the proxy is notified of the change
lproxy[0] = d
```

This approach is perhaps less convenient than employing nested **Proxy Objects** for most use cases but also demonstrates a level of control over the synchronization.

## Note

The proxy types in `multiprocessing` do nothing to support comparisons by value. So, for instance, we have:

```
>>> manager.list([1,2,3]) == [1,2,3]
False
```

One should just use a copy of the referent instead when making comparisons.

`class multiprocessing.managers.BaseProxy`

Proxy objects are instances of subclasses of `BaseProxy`.

`_callmethod(methodname[, args[, kwds]])`

Call and return the result of a method of the proxy's referent.

If `proxy` is a proxy whose referent is `obj` then the expression

```
proxy._callmethod(methodname, args, kwds)
```

will evaluate the expression

```
getattr(obj, methodname)(*args, **kwds)
```

in the manager's process.

The returned value will be a copy of the result of the call or a proxy to a new shared object – see documentation for the `method_to_typeid` argument of `BaseManager.register()`.

If an exception is raised by the call, then is re-raised by `_callmethod()`. If some other exception is raised in the manager's process then this is converted into a `RemoteError` exception and is raised by `_callmethod()`.

Note in particular that an exception will be raised if *methodname* has not been *exposed*.

An example of the usage of `_callmethod()`:

```
>>> l = manager.list(range(10))
>>> l._callmethod('__len__')
10
>>> l._callmethod('__getitem__', (slice(2, 7),))
[2, 3, 4, 5, 6]
>>> l._callmethod('__getitem__', (20,))
Traceback (most recent call last):
...
IndexError: list index out of range
```

### `_getvalue()`

Return a copy of the referent.

If the referent is unpicklable then this will raise an exception.

### `_repr_()`

Return a representation of the proxy object.

### `_str_()`

Return the representation of the referent.

## Cleanup

A proxy object uses a weakref callback so that when it gets garbage collected it deregisters itself from the manager which owns its referent.

A shared object gets deleted from the manager process when there are no longer any proxies referring to it.

## Process Pools

One can create a pool of processes which will carry out tasks submitted to it with the `Pool` class.

```
class multiprocessing.pool.Pool([processes[, initializer[, initargs[,  
maxtasksperchild[, context]]]]])
```

A process pool object which controls a pool of worker processes to which jobs can be submitted. It supports asynchronous results with timeouts and callbacks and has a parallel map implementation.

*processes* is the number of worker processes to use. If *processes* is `None` then the number returned by `os.cpu_count()` is used.

If *initializer* is not `None` then each worker process will call `initializer(*initargs)` when it starts.

*maxtasksperchild* is the number of tasks a worker process can complete before it will exit and be replaced with a fresh worker process, to enable unused resources to be freed. The default *maxtasksperchild* is `None`, which means worker processes will live as long as the pool.

*context* can be used to specify the context used for starting the worker processes. Usually a pool is created using the function `multiprocessing.Pool()` or the `Pool()` method of a context object. In both cases *context* is set appropriately.

Note that the methods of the pool object should only be called by the process which created the pool.

## Warning

`multiprocessing.pool` objects have internal resources that need to be properly managed (like any other resource) by using the pool as a context manager or by calling `close()` and `terminate()` manually. Failure to do this can lead to the process hanging on finalization.

Note that it is **not correct** to rely on the garbage collector to destroy the pool as CPython does not assure that the

finalizer of the pool will be called (see `object.__del__()` for more information).

*New in version 3.2: `maxtasksperchild`*

*New in version 3.4: `context`*

## Note

Worker processes within a `Pool` typically live for the complete duration of the Pool's work queue. A frequent pattern found in other systems (such as Apache, `mod_wsgi`, etc) to free resources held by workers is to allow a worker within a pool to complete only a set amount of work before being exiting, being cleaned up and a new process spawned to replace the old one. The `maxtasksperchild` argument to the `Pool` exposes this ability to the end user.

`apply(func[, args[, kwds]])`

Call *func* with arguments *args* and keyword arguments *kwds*. It blocks until the result is ready. Given this blocks, `apply_async()` is better suited for performing work in parallel. Additionally, *func* is only executed in one of the workers of the pool.

`apply_async(func[, args[, kwds[, callback[,  
error_callback]]]])`

A variant of the `apply()` method which returns a `AsyncResult` object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it, that is unless the call failed, in which case the *error\_callback* is applied instead.

If *error\_callback* is specified then it should be a callable which accepts a single argument. If the target function

fails, then the *error\_callback* is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

`map(func, iterable[, chunksize])`

A parallel equivalent of the `map()` built-in function (it supports only one *iterable* argument though, for multiple iterables see `starmap()`). It blocks until the result is ready.

This method chops the iterable into a number of chunks which it submits to the process pool as separate tasks. The (approximate) size of these chunks can be specified by setting *chunksize* to a positive integer.

Note that it may cause high memory usage for very long iterables. Consider using `imap()` or `imap_unordered()` with explicit *chunksize* option for better efficiency.

`map_async(func, iterable[, chunksize[, callback[, error_callback]]])`

A variant of the `map()` method which returns a `AsyncResult` object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it, that is unless the call failed, in which case the *error\_callback* is applied instead.

If *error\_callback* is specified then it should be a callable which accepts a single argument. If the target function fails, then the *error\_callback* is called with the exception instance.

Callbacks should complete immediately since otherwise

the thread which handles the results will get blocked.

`imap(func, iterable[, chunksize])`

A lazier version of `map()`.

The *chunksize* argument is the same as the one used by the `map()` method. For very long iterables using a large value for *chunksize* can make the job complete **much** faster than using the default value of `1`.

Also if *chunksize* is `1` then the `next()` method of the iterator returned by the `imap()` method has an optional *timeout* parameter: `next(timeout)` will raise `multiprocessing.TimeoutError` if the result cannot be returned within *timeout* seconds.

`imap_unordered(func, iterable[, chunksize])`

The same as `imap()` except that the ordering of the results from the returned iterator should be considered arbitrary. (Only when there is only one worker process is the order guaranteed to be “correct”.)

`starmap(func, iterable[, chunksize])`

Like `map()` except that the elements of the *iterable* are expected to be iterables that are unpacked as arguments.

Hence an *iterable* of `[(1, 2), (3, 4)]` results in `[func(1, 2), func(3, 4)]`.

*New in version 3.3.*

`starmap_async(func, iterable[, chunksize[, callback[, error_callback]]])`

A combination of `starmap()` and `map_async()` that iterates over *iterable* of iterables and calls *func* with the iterables unpacked. Returns a result object.

*New in version 3.3.*

`close()`

Prevents any more tasks from being submitted to the pool. Once all the tasks have been completed the worker processes will exit.

`terminate()`

Stops the worker processes immediately without completing outstanding work. When the pool object is garbage collected `terminate()` will be called immediately.

`join()`

Wait for the worker processes to exit. One must call `close()` or `terminate()` before using `join()`.

*New in version 3.3:* Pool objects now support the context management protocol – see [Context Manager Types](#).

`__enter__()` returns the pool object, and `__exit__()` calls `terminate()`.

*class* `multiprocessing.pool.AsyncResult`

The class of the result returned by `Pool.apply_async()` and `Pool.map_async()`.

`get([timeout])`

Return the result when it arrives. If *timeout* is not `None` and the result does not arrive within *timeout* seconds then `multiprocessing.TimeoutError` is raised. If the remote call raised an exception then that exception will be reraised by `get()`.

`wait([timeout])`

Wait until the result is available or until *timeout* seconds pass.

`ready()`

Return whether the call has completed.

`successful()`

Return whether the call completed without raising an exception. Will raise `ValueError` if the result is not ready.

*Changed in version 3.7:* If the result is not ready, `ValueError` is raised instead of `AssertionError`.

The following example demonstrates the use of a pool:

```
from multiprocessing import Pool
import time

def f(x):
    return x*x

if __name__ == '__main__':
    with Pool(processes=4) as pool:
        # start 4 workers
        result = pool.apply_async(f, (10,)) # evaluate "f(10)"
        print(result.get(timeout=1))        # prints "100"

        print(pool.map(f, range(10)))      # prints "[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]"

        it = pool.imap(f, range(10))
        print(next(it))                     # prints "0"
        print(next(it))                     # prints "1"
        print(it.next(timeout=1))           # prints "4"

        result = pool.apply_async(time.sleep, (10,))
        print(result.get(timeout=1))        # raises multiprocessing.TimeoutError
```

## Listeners and Clients

Usually message passing between processes is done using queues or by using `Connection` objects returned by `Pipe()`.

However, the `multiprocessing.connection` module allows some extra flexibility. It basically gives a high level message oriented API for dealing with sockets or Windows named pipes. It also has support for *digest authentication* using the `hmac` module, and for polling multiple connections at the same time.

`multiprocessing.connection.deliver_challenge(connection, authkey)`

Send a randomly generated message to the other end of the connection and wait for a reply.

If the reply matches the digest of the message using *authkey* as the key then a welcome message is sent to the other end of the connection. Otherwise `AuthenticationError` is raised.

`multiprocessing.connection.answer_challenge(connection, authkey)`

Receive a message, calculate the digest of the message using *authkey* as the key, and then send the digest back.

If a welcome message is not received, then `AuthenticationError` is raised.

`multiprocessing.connection.Client(address[, family[, authkey]])`

Attempt to set up a connection to the listener which is using address *address*, returning a `Connection`.

The type of the connection is determined by *family* argument, but this can generally be omitted since it can usually be inferred from the format of *address*. (See [Address Formats](#))

If *authkey* is given and not None, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if *authkey* is None. `AuthenticationError` is raised if authentication fails. See [Authentication keys](#).

`class multiprocessing.connection.Listener([address[, family[, backlog[, authkey]]]])`

A wrapper for a bound socket or Windows named pipe which is 'listening' for connections.

*address* is the address to be used by the bound socket or named pipe of the listener object.

### Note

If an address of '0.0.0.0' is used, the address will not be a connectable end point on Windows. If you require a connectable end-point, you should use '127.0.0.1'.

*family* is the type of socket (or named pipe) to use. This can be one of the strings 'AF\_INET' (for a TCP socket), 'AF\_UNIX' (for a Unix domain socket) or 'AF\_PIPE' (for a Windows named pipe). Of these only the first is guaranteed to be available. If *family* is `None` then the family is inferred from the format of *address*. If *address* is also `None` then a default is chosen. This default is the family which is assumed to be the fastest available. See [Address Formats](#). Note that if *family* is 'AF\_UNIX' and *address* is `None` then the socket will be created in a private temporary directory created using `tempfile.mkstemp()`.

If the listener object uses a socket then *backlog* (1 by default) is passed to the `listen()` method of the socket once it has been bound.

If *authkey* is given and not `None`, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if *authkey* is `None`. `AuthenticationError` is raised if authentication fails. See [Authentication keys](#).

### `accept()`

Accept a connection on the bound socket or named pipe of the listener object and return a `Connection` object. If authentication is attempted and fails, then `AuthenticationError` is raised.

`close()`

Close the bound socket or named pipe of the listener object. This is called automatically when the listener is garbage collected. However it is advisable to call it explicitly.

Listener objects have the following read-only properties:

`address`

The address which is being used by the Listener object.

`last_accepted`

The address from which the last accepted connection came. If this is unavailable then it is `None`.

*New in version 3.3:* Listener objects now support the context management protocol – see [Context Manager Types](#).

`__enter__()` returns the listener object, and `__exit__()` calls `close()`.

`multiprocessing.connection.wait(object_list, timeout=None)`

Wait till an object in *object\_list* is ready. Returns the list of those objects in *object\_list* which are ready. If *timeout* is a float then the call blocks for at most that many seconds. If *timeout* is `None` then it will block for an unlimited period. A negative timeout is equivalent to a zero timeout.

For both Unix and Windows, an object can appear in *object\_list* if it is

- a readable [Connection](#) object;
- a connected and readable `socket.socket` object; or
- the `sentinel` attribute of a [Process](#) object.

A connection or socket object is ready when there is data available to be read from it, or the other end has been closed.

**Unix:** `wait(object_list, timeout)` almost equivalent `select.select(object_list, [], [], timeout)`.

The difference is that, if `select.select()` is interrupted by a signal, it can raise `OSError` with an error number of `EINTR`, whereas `wait()` will not.

**Windows:** An item in *object\_list* must either be an integer handle which is waitable (according to the definition used by the documentation of the Win32 function `WaitForMultipleObjects()`) or it can be an object with a **`fileno()`** method which returns a socket handle or pipe handle. (Note that pipe handles and socket handles are **not** waitable handles.)

*New in version 3.3.*

## Examples

The following server code creates a listener which uses 'secret password' as an authentication key. It then waits for a connection and sends some data to the client:

```
from multiprocessing.connection import Listener
from array import array

address = ('localhost', 6000)      # family is deduced to
with Listener(address, authkey=b'secret password') as li
    with listener.accept() as conn:
        print('connection accepted from', listener.last_
            conn.send([2.25, None, 'junk', float])

        conn.send_bytes(b'hello')

        conn.send_bytes(array('i', [42, 1729]))
```

The following code connects to the server and receives some data from the server:

```
from multiprocessing.connection import Client
from array import array
```

```

address = ('localhost', 6000)

with Client(address, authkey=b'secret password') as conn:
    print(conn.recv())          # => [2.25, None]

    print(conn.recv_bytes())    # => 'hello'

    arr = array('i', [0, 0, 0, 0, 0])
    print(conn.recv_bytes_into(arr))  # => 8
    print(arr)                  # => array('i',

```

The following code uses `wait()` to wait for messages from multiple processes at once:

```

import time, random
from multiprocessing import Process, Pipe, current_process
from multiprocessing.connection import wait

def foo(w):
    for i in range(10):
        w.send((i, current_process().name))
    w.close()

if __name__ == '__main__':
    readers = []

    for i in range(4):
        r, w = Pipe(duplex=False)
        readers.append(r)
        p = Process(target=foo, args=(w,))
        p.start()
        # We close the writable end of the pipe now to block
        # p is the only process which owns a handle for the
        # ensures that when p closes its handle for the
        # wait() will promptly report the readable end as closed
        w.close()

    while readers:

```

```

for r in wait(readers):
    try:
        msg = r.recv()
    except EOFError:
        readers.remove(r)
    else:
        print(msg)

```

## Address Formats

- An 'AF\_INET' address is a tuple of the form (hostname, port) where *hostname* is a string and *port* is an integer.
- An 'AF\_UNIX' address is a string representing a filename on the filesystem.
- An 'AF\_PIPE' address is a string of the form `r'\\.\pipe\PipeName'`. To use `Client()` to connect to a named pipe on a remote computer called *ServerName* one should use an address of the form `r'\\ServerName\pipe\PipeName'` instead.

Note that any string beginning with two backslashes is assumed by default to be an 'AF\_PIPE' address rather than an 'AF\_UNIX' address.

## Authentication keys

When one uses `Connection.recv`, the data received is automatically unpickled. Unfortunately unpickling data from an untrusted source is a security risk. Therefore `Listener` and `Client()` use the `hmac` module to provide digest authentication.

An authentication key is a byte string which can be thought of as a password: once a connection is established both ends will demand proof that the other knows the authentication key. (Demonstrating that both ends are using the same key does **not** involve sending the key over the connection.)

If authentication is requested but no authentication key is specified then the return value of `current_process().authkey` is used (see `Process`). This value will be automatically inherited by any

**Process** object that the current process creates. This means that (by default) all processes of a multi-process program will share a single authentication key which can be used when setting up connections between themselves.

Suitable authentication keys can also be generated by using `os.urandom()`.

## Logging

Some support for logging is available. Note, however, that the **logging** package does not use process shared locks so it is possible (depending on the handler type) for messages from different processes to get mixed up.

`multiprocessing.get_logger()`

Returns the logger used by **multiprocessing**. If necessary, a new one will be created.

When first created the logger has level **logging.NOTSET** and no default handler. Messages sent to this logger will not by default propagate to the root logger.

Note that on Windows child processes will only inherit the level of the parent process's logger – any other customization of the logger will not be inherited.

`multiprocessing.log_to_stderr(level=None)`

This function performs a call to `get_logger()` but in addition to returning the logger created by `get_logger`, it adds a handler which sends output to **sys.stderr** using format `'[% (levelname) s/% (processName) s] %(message) s'`. You can modify `levelname` of the logger by passing a `level` argument.

Below is an example session with logging turned on:

```
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
```

```
>>> logger.setLevel(logging.INFO)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
[INFO/SyncManager-...] child process calling self.run()
[INFO/SyncManager-...] created temp directory /.../pypm-
[INFO/SyncManager-...] manager serving at '/.../listener
>>> del m
[INFO/MainProcess] sending shutdown message to manager
[INFO/SyncManager-...] manager exiting with exitcode 0
```

For a full table of logging levels, see the [logging](#) module.

## The [multiprocessing.dummy](#) module

[multiprocessing.dummy](#) replicates the API of [multiprocessing](#) but is no more than a wrapper around the [threading](#) module.

In particular, the `Pool` function provided by [multiprocessing.dummy](#) returns an instance of [ThreadPool](#), which is a subclass of [Pool](#) that supports all the same method calls but uses a pool of worker threads rather than worker processes.

```
class multiprocessing.pool.ThreadPool([processes[, initializer[,
initargs]]])
```

A thread pool object which controls a pool of worker threads to which jobs can be submitted. [ThreadPool](#) instances are fully interface compatible with [Pool](#) instances, and their resources must also be properly managed, either by using the pool as a context manager or by calling [close\(\)](#) and [terminate\(\)](#) manually.

*processes* is the number of worker threads to use. If *processes* is `None` then the number returned by [os.cpu\\_count\(\)](#) is used.

If *initializer* is not `None` then each worker process will call `initializer(*initargs)` when it starts.

Unlike `Pool`, `maxtasksperchild` and `context` cannot be provided.

### Note

A `ThreadPool` shares the same interface as `Pool`, which is designed around a pool of processes and predates the introduction of the `concurrent.futures` module. As such, it inherits some operations that don't make sense for a pool backed by threads, and it has its own type for representing the status of asynchronous jobs, `AsyncResult`, that is not understood by any other libraries.

Users should generally prefer to use `concurrent.futures.ThreadPoolExecutor`, which has a simpler interface that was designed around threads from the start, and which returns `concurrent.futures.Future` instances that are compatible with many other libraries, including `asyncio`.

## Programming guidelines

There are certain guidelines and idioms which should be adhered to when using `multiprocessing`.

### All start methods

The following applies to all start methods.

Avoid shared state

As far as possible one should try to avoid shifting large amounts of data between processes.

It is probably best to stick to using queues or pipes for communication between processes rather than using the lower level synchronization primitives.

### Picklability

Ensure that the arguments to the methods of proxies are picklable.

### Thread safety of proxies

Do not use a proxy object from more than one thread unless you protect it with a lock.

(There is never a problem with different processes using the *same* proxy.)

### Joining zombie processes

On Unix when a process finishes but has not been joined it becomes a zombie. There should never be very many because each time a new process starts (or `active_children()` is called) all completed processes which have not yet been joined will be joined. Also calling a finished process's `Process.is_alive` will join the process. Even so it is probably good practice to explicitly join all the processes that you start.

### Better to inherit than pickle/unpickle

When using the *spawn* or *forkserver* start methods many types from `multiprocessing` need to be picklable so that child processes can use them. However, one should generally avoid sending shared objects to other processes using pipes or queues. Instead you should arrange the program so that a process which needs access to a shared resource created elsewhere can inherit it from an ancestor process.

### Avoid terminating processes

Using the `Process.terminate` method to stop a process is liable to cause any shared resources (such as locks, semaphores, pipes and queues) currently being used by the process to become broken or unavailable to other processes.

Therefore it is probably best to only consider using `Process.terminate` on processes which never use any shared resources.

## Joining processes that use queues

Bear in mind that a process that has put items in a queue will wait before terminating until all the buffered items are fed by the “feeder” thread to the underlying pipe. (The child process can call the `Queue.cancel_join_thread` method of the queue to avoid this behaviour.)

This means that whenever you use a queue you need to make sure that all items which have been put on the queue will eventually be removed before the process is joined. Otherwise you cannot be sure that processes which have put items on the queue will terminate. Remember also that non-daemonic processes will be joined automatically.

An example which will deadlock is the following:

```
from multiprocessing import Process, Queue

def f(q):
    q.put('X' * 1000000)

if __name__ == '__main__':
    queue = Queue()
    p = Process(target=f, args=(queue,))
    p.start()
    p.join()
    obj = queue.get()
```

A fix here would be to swap the last two lines (or simply remove the `p.join()` line).

Explicitly pass resources to child processes

On Unix using the *fork* start method, a child process can make use of a shared resource created in a parent process using a global resource. However, it is better to pass the object as an argument to the constructor for the child process.

Apart from making the code (potentially) compatible with Windows and the other start methods this also ensures that as long as the child process is still alive the object will not be garbage collected in the parent process. This might be important if some resource is freed when the object is garbage collected in the parent process.

So for instance

```
from multiprocessing import Process, Lock

def f():
    ... do something using "lock" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f).start()
```

should be rewritten as

```
from multiprocessing import Process, Lock

def f(l):
    ... do something using "l" ...

if __name__ == '__main__':
    lock = Lock()
```

```
for i in range(10):
    Process(target=f, args=(lock,)).start()
```

Beware of replacing **`sys.stdin`** with a “file like object”

**`multiprocessing`** originally unconditionally called:

```
os.close(sys.stdin.fileno())
```

in the

**`multiprocessing.Process._bootstrap()`** method — this resulted in issues with processes-in-processes. This has been changed to:

```
sys.stdin.close()
sys.stdin = open(os.open(os.devnull, os.O_RDONLY),
```

Which solves the fundamental issue of processes colliding with each other resulting in a bad file descriptor error, but introduces a potential danger to applications which replace **`sys.stdin()`** with a “file-like object” with output buffering. This danger is that if multiple processes call **`close()`** on this file-like object, it could result in the same data being flushed to the object multiple times, resulting in corruption.

If you write a file-like object and implement your own caching, you can make it fork-safe by storing the pid whenever you append to the cache, and discarding the cache when the pid changes. For example:

```
@property
def cache(self):
    pid = os.getpid()
    if pid != self._pid:
        self._pid = pid
        self._cache = []
    return self._cache
```

For more information, see [bpo-5155](https://bugs.python.org/issue?@action=redirect&bpo=5155) [https://bugs.python.org/issue?@action=redirect&bpo=5155], [bpo-5313](https://bugs.python.org/issue?@action=redirect&bpo=5313) [https://bugs.python.org/issue?@action=redirect&bpo=5313] and [bpo-5331](https://bugs.python.org/issue?@action=redirect&bpo=5331) [https://bugs.python.org/issue?@action=redirect&bpo=5331]

## The *spawn* and *forkserver* start methods

There are a few extra restriction which don't apply to the *fork* start method.

### More picklability

Ensure that all arguments to `Process.__init__()` are pickleable. Also, if you subclass `Process` then make sure that instances will be pickleable when the `Process.start` method is called.

### Global variables

Bear in mind that if code run in a child process tries to access a global variable, then the value it sees (if any) may not be the same as the value in the parent process at the time that `Process.start` was called.

However, global variables which are just module level constants cause no problems.

### Safe importing of main module

Make sure that the main module can be safely imported by a new Python interpreter without causing unintended side effects (such a starting a new process).

For example, using the *spawn* or *forkserver* start method running the following module would fail with a `RuntimeError`:

```
from multiprocessing import Process

def foo():
    print('hello')

p = Process(target=foo)
p.start()
```

Instead one should protect the “entry point” of the program by using `if __name__ == '__main__':` as follows:

```
from multiprocessing import Process, freeze_support

def foo():
    print('hello')

if __name__ == '__main__':
    freeze_support()
    set_start_method('spawn')
    p = Process(target=foo)
    p.start()
```

(The `freeze_support()` line can be omitted if the program will be run normally instead of frozen.)

This allows the newly spawned Python interpreter to safely import the module and then run the module’s `foo()` function.

Similar restrictions apply if a pool or manager is created in the main module.

## Examples

Demonstration of how to create and use customized managers and proxies:

```
from multiprocessing import freeze_support
```

```
from multiprocessing.managers import BaseManager, BaseProxy
import operator

##

class Foo:
    def f(self):
        print('you called Foo.f()')
    def g(self):
        print('you called Foo.g()')
    def _h(self):
        print('you called Foo._h()')

# A simple generator function
def baz():
    for i in range(10):
        yield i*i

# Proxy type for generator objects
class GeneratorProxy(BaseProxy):
    _exposed_ = ['__next__']
    def __iter__(self):
        return self
    def __next__(self):
        return self._callmethod('__next__')

# Function to return the operator module
def get_operator_module():
    return operator

##

class MyManager(BaseManager):
    pass

# register the Foo class; make `f()` and `g()` accessible
MyManager.register('Foo1', Foo)
```

```

# register the Foo class; make `g()` and `_h()` accessible
MyManager.register('Foo2', Foo, exposed=('g', '_h'))

# register the generator function baz; use `GeneratorProxy`
MyManager.register('baz', baz, proxytype=GeneratorProxy)

# register get_operator_module(); make public functions
MyManager.register('operator', get_operator_module)

##

def test():
    manager = MyManager()
    manager.start()

    print('-' * 20)

    f1 = manager.Foo1()
    f1.f()
    f1.g()
    assert not hasattr(f1, '_h')
    assert sorted(f1._exposed_) == sorted(['f', 'g'])

    print('-' * 20)

    f2 = manager.Foo2()
    f2.g()
    f2._h()
    assert not hasattr(f2, 'f')
    assert sorted(f2._exposed_) == sorted(['g', '_h'])

    print('-' * 20)

    it = manager.baz()
    for i in it:
        print('<%d>' % i, end=' ')
    print()

```

```
print('-' * 20)

op = manager.operator()
print('op.add(23, 45) =', op.add(23, 45))
print('op.pow(2, 94) =', op.pow(2, 94))
print('op._exposed_ =', op._exposed_)
```

```
##
```

```
if __name__ == '__main__':
    freeze_support()
    test()
```

### Using **Pool**:

```
import multiprocessing
import time
import random
import sys

#
# Functions used by test code
#

def calculate(func, args):
    result = func(*args)
    return '%s says that %s%s = %s' % (
        multiprocessing.current_process().name,
        func.__name__, args, result
    )

def calculatestar(args):
    return calculate(*args)

def mul(a, b):
    time.sleep(0.5 * random.random())
    return a * b

def plus(a, b):
```

```

    time.sleep(0.5 * random.random())
    return a + b

def f(x):
    return 1.0 / (x - 5.0)

def pow3(x):
    return x ** 3

def noop(x):
    pass

#
# Test code
#

def test():
    PROCESSES = 4
    print('Creating pool with %d processes\n' % PROCESSES)

    with multiprocessing.Pool(PROCESSES) as pool:
        #
        # Tests
        #

        TASKS = [(mul, (i, 7)) for i in range(10)] + \
                [(plus, (i, 8)) for i in range(10)]

        results = [pool.apply_async(calculate, t) for t in TASKS]
        imap_it = pool.imap(calculatestar, TASKS)
        imap_unordered_it = pool.imap_unordered(calculatestar, TASKS)

        print('Ordered results using pool.apply_async():')
        for r in results:
            print('\t', r.get())
        print()

        print('Ordered results using pool.imap():')

```

```

for x in imap_it:
    print('\t', x)
print()

print('Unordered results using pool.imap_unordered')
for x in imap_unordered_it:
    print('\t', x)
print()

print('Ordered results using pool.map() --- will')
for x in pool.map(calculatestar, TASKS):
    print('\t', x)
print()

#
# Test error handling
#

print('Testing error handling:')

try:
    print(pool.apply(f, (5,)))
except ZeroDivisionError:
    print('\tGot ZeroDivisionError as expected')
else:
    raise AssertionError('expected ZeroDivisionError')

try:
    print(pool.map(f, list(range(10))))
except ZeroDivisionError:
    print('\tGot ZeroDivisionError as expected')
else:
    raise AssertionError('expected ZeroDivisionError')

try:
    print(list(pool.imap(f, list(range(10)))))
except ZeroDivisionError:
    print('\tGot ZeroDivisionError as expected')

```

```

else:
    raise AssertionError('expected ZeroDivisionError')

it = pool.imap(f, list(range(10)))
for i in range(10):
    try:
        x = next(it)
    except ZeroDivisionError:
        if i == 5:
            pass
    except StopIteration:
        break
    else:
        if i == 5:
            raise AssertionError('expected ZeroDivisionError')

assert i == 9
print('\tGot ZeroDivisionError as expected from')
print()

#
# Testing timeouts
#

print('Testing ApplyResult.get() with timeout:',
      res = pool.apply_async(calculate, TASKS[0])
while 1:
    sys.stdout.flush()
    try:
        sys.stdout.write('\n\t%s' % res.get(0.02))
        break
    except multiprocessing.TimeoutError:
        sys.stdout.write('.')
print()
print()

print('Testing IMapIterator.next() with timeout:')
it = pool.imap(calculatestar, TASKS)

```

```

while 1:
    sys.stdout.flush()
    try:
        sys.stdout.write('\n\t%s' % it.next(0.02))
    except StopIteration:
        break
    except multiprocessing.TimeoutError:
        sys.stdout.write('.')
print()
print()

if __name__ == '__main__':
    multiprocessing.freeze_support()
    test()

```

**An example showing how to use queues to feed tasks to a collection of worker processes and collect the results:**

```

import time
import random

from multiprocessing import Process, Queue, current_process

#
# Function run by worker processes
#

def worker(input, output):
    for func, args in iter(input.get, 'STOP'):
        result = calculate(func, args)
        output.put(result)

#
# Function used to calculate result
#

def calculate(func, args):
    result = func(*args)

```

```

        return '%s says that %s%s = %s' % \
            (current_process().name, func.__name__, args, re

#
# Functions referenced by tasks
#

def mul(a, b):
    time.sleep(0.5*random.random())
    return a * b

def plus(a, b):
    time.sleep(0.5*random.random())
    return a + b

#
#
#

def test():
    NUMBER_OF_PROCESSES = 4
    TASKS1 = [(mul, (i, 7)) for i in range(20)]
    TASKS2 = [(plus, (i, 8)) for i in range(10)]

    # Create queues
    task_queue = Queue()
    done_queue = Queue()

    # Submit tasks
    for task in TASKS1:
        task_queue.put(task)

    # Start worker processes
    for i in range(NUMBER_OF_PROCESSES):
        Process(target=worker, args=(task_queue, done_queue,

    # Get and print results
    print('Unordered results:')

```

```
for i in range(len(TASKS1)):
    print('\t', done_queue.get())

# Add more tasks using `put()`
for task in TASKS2:
    task_queue.put(task)

# Get and print some more results
for i in range(len(TASKS2)):
    print('\t', done_queue.get())

# Tell child processes to stop
for i in range(NUMBER_OF_PROCESSES):
    task_queue.put('STOP')

if __name__ == '__main__':
    freeze_support()
    test()
```

# multiprocessing.shared\_memory

## — Shared memory for direct access across processes

**Source code:** [Lib/multiprocessing/shared\\_memory.py](https://github.com/python/cpython/tree/3.11/Lib/multiprocessing/shared_memory.py) [https://github.com/python/cpython/tree/3.11/Lib/multiprocessing/shared\_memory.py]

*New in version 3.8.*

---

This module provides a class, **SharedMemory**, for the allocation and management of shared memory to be accessed by one or more processes on a multicore or symmetric multiprocessor (SMP) machine. To assist with the life-cycle management of shared memory especially across distinct processes, a **BaseManager** subclass, **SharedMemoryManager**, is also provided in the `multiprocessing.managers` module.

In this module, shared memory refers to “System V style” shared memory blocks (though is not necessarily implemented explicitly as such) and does not refer to “distributed shared memory”. This style of shared memory permits distinct processes to potentially read and write to a common (or shared) region of volatile memory. Processes are conventionally limited to only have access to their own process memory space but shared memory permits the sharing of data between processes, avoiding the need to instead send messages between processes containing that data. Sharing data directly via memory can provide significant performance benefits compared to sharing data via disk or socket or other communications requiring the serialization/deserialization and copying of data.

```
class multiprocessing.shared_memory.SharedMemory(name=None,
create=False, size=0)
```

Creates a new shared memory block or attaches to an existing

shared memory block. Each shared memory block is assigned a unique name. In this way, one process can create a shared memory block with a particular name and a different process can attach to that same shared memory block using that same name.

As a resource for sharing data across processes, shared memory blocks may outlive the original process that created them. When one process no longer needs access to a shared memory block that might still be needed by other processes, the `close()` method should be called. When a shared memory block is no longer needed by any process, the `unlink()` method should be called to ensure proper cleanup.

*name* is the unique name for the requested shared memory, specified as a string. When creating a new shared memory block, if `None` (the default) is supplied for the name, a novel name will be generated.

*create* controls whether a new shared memory block is created (`True`) or an existing shared memory block is attached (`False`).

*size* specifies the requested number of bytes when creating a new shared memory block. Because some platforms choose to allocate chunks of memory based upon that platform's memory page size, the exact size of the shared memory block may be larger or equal to the size requested. When attaching to an existing shared memory block, the *size* parameter is ignored.

`close()`

Closes access to the shared memory from this instance. In order to ensure proper cleanup of resources, all instances should call `close()` once the instance is no longer needed. Note that calling `close()` does not cause the shared memory block itself to be destroyed.

`unlink()`

Requests that the underlying shared memory block be

destroyed. In order to ensure proper cleanup of resources, `unlink()` should be called once (and only once) across all processes which have need for the shared memory block. After requesting its destruction, a shared memory block may or may not be immediately destroyed and this behavior may differ across platforms. Attempts to access data inside the shared memory block after `unlink()` has been called may result in memory access errors. Note: the last process relinquishing its hold on a shared memory block may call `unlink()` and `close()` in either order.

`buf`

A memoryview of contents of the shared memory block.

`name`

Read-only access to the unique name of the shared memory block.

`size`

Read-only access to size in bytes of the shared memory block.

The following example demonstrates low-level use of `SharedMemory` instances:

```
>>> from multiprocessing import shared_memory
>>> shm_a = shared_memory.SharedMemory(create=True, size=10)
>>> type(shm_a.buf)
<class 'memoryview'>
>>> buffer = shm_a.buf
>>> len(buffer)
10
>>> buffer[:4] = bytearray([22, 33, 44, 55]) # Modify memory
>>> buffer[4] = 100 # Modify size
>>> # Attach to an existing shared memory block
>>> shm_b = shared_memory.SharedMemory(shm_a.name)
>>> import array
```

```
>>> array.array('b', shm_b.buf[:5]) # Copy the data into
array('b', [22, 33, 44, 55, 100])
>>> shm_b.buf[:5] = b'howdy' # Modify via shm_b using b
>>> bytes(shm_a.buf[:5]) # Access via shm_a
b'howdy'
>>> shm_b.close() # Close each SharedMemory instance
>>> shm_a.close()
>>> shm_a.unlink() # Call unlink only once to release t
```

The following example demonstrates a practical use of the **SharedMemory** class with **NumPy arrays** [\[https://numpy.org/\]](https://numpy.org/), accessing the same `numpy.ndarray` from two distinct Python shells:

```
>>> # In the first Python interactive shell
>>> import numpy as np
>>> a = np.array([1, 1, 2, 3, 5, 8]) # Start with an ex
>>> from multiprocessing import shared_memory
>>> shm = shared_memory.SharedMemory(create=True, size=a
>>> # Now create a NumPy array backed by shared memory
>>> b = np.ndarray(a.shape, dtype=a.dtype, buffer=shm.bu
>>> b[:] = a[:] # Copy the original data into shared me
>>> b
array([1, 1, 2, 3, 5, 8])
>>> type(b)
<class 'numpy.ndarray'>
>>> type(a)
<class 'numpy.ndarray'>
>>> shm.name # We did not specify a name so one was cho
'psm_21467_46075'

>>> # In either the same shell or a new Python shell on
>>> import numpy as np
>>> from multiprocessing import shared_memory
>>> # Attach to the existing shared memory block
>>> existing_shm = shared_memory.SharedMemory(name='psm_
>>> # Note that a.shape is (6,) and a.dtype is np.int64
>>> c = np.ndarray((6,), dtype=np.int64, buffer=existing
>>> c
```

```

array([1, 1, 2, 3, 5, 8])
>>> c[-1] = 888
>>> c
array([ 1, 1, 2, 3, 5, 888])

>>> # Back in the first Python interactive shell, b refl
>>> b
array([ 1, 1, 2, 3, 5, 888])

>>> # Clean up from within the second Python shell
>>> del c # Unnecessary; merely emphasizing the array i
>>> existing_shm.close()

>>> # Clean up from within the first Python shell
>>> del b # Unnecessary; merely emphasizing the array i
>>> shm.close()
>>> shm.unlink() # Free and release the shared memory b

```

```

class multiprocessing.managers.SharedMemoryManager([address[,
authkey]])

```

A subclass of **BaseManager** which can be used for the management of shared memory blocks across processes.

A call to **start()** on a **SharedMemoryManager** instance causes a new process to be started. This new process's sole purpose is to manage the life cycle of all shared memory blocks created through it. To trigger the release of all shared memory blocks managed by that process, call **shutdown()** on the instance. This triggers a **SharedMemory.unlink()** call on all of the **SharedMemory** objects managed by that process and then stops the process itself. By creating **SharedMemory** instances through a **SharedMemoryManager**, we avoid the need to manually track and trigger the freeing of shared memory resources.

This class provides methods for creating and returning **SharedMemory** instances and for creating a list-like object (**ShareableList**) backed by shared memory.

Refer to `multiprocessing.managers.BaseManager` for a description of the inherited *address* and *authkey* optional input arguments and how they may be used to connect to an existing `SharedMemoryManager` service from other processes.

`SharedMemory(size)`

Create and return a new `SharedMemory` object with the specified `size` in bytes.

`ShareableList(sequence)`

Create and return a new `ShareableList` object, initialized by the values from the input `sequence`.

The following example demonstrates the basic mechanisms of a **SharedMemoryManager**:

```
>>> from multiprocessing.managers import SharedMemoryManager
>>> smm = SharedMemoryManager()
>>> smm.start() # Start the process that manages the shared memory
>>> sl = smm.ShareableList(range(4))
>>> sl
ShareableList([0, 1, 2, 3], name='psm_6572_7512')
>>> raw_shm = smm.SharedMemory(size=128)
>>> another_sl = smm.ShareableList('alpha')
>>> another_sl
ShareableList(['a', 'l', 'p', 'h', 'a'], name='psm_6572_7512')
>>> smm.shutdown() # Calls unlink() on sl, raw_shm, and another_sl
```

The following example depicts a potentially more convenient pattern for using **SharedMemoryManager** objects via the `with` statement to ensure that all shared memory blocks are released after they are no longer needed:

```
>>> with SharedMemoryManager() as smm:
...     sl = smm.ShareableList(range(2000))
...     # Divide the work among two processes, storing p1 and p2
...     p1 = Process(target=do_work, args=(sl, 0, 1000))
...     p2 = Process(target=do_work, args=(sl, 1000, 2000))
...     p1.start()
...     p2.start()
...     p1.join()
...     p2.join()
```

```
...     p1.start()
...     p2.start()    # A multiprocessing.Pool might be mo
...     p1.join()
...     p2.join()    # Wait for all work to complete in b
...     total_result = sum(sl)    # Consolidate the partial
```

When using a **SharedMemoryManager** in a **with** statement, the shared memory blocks created using that manager are all released when the **with** statement's code block finishes execution.

*class multiprocessing.shared\_memory.ShareableList(sequence=None, \*, name=None)*

Provides a mutable list-like object where all values stored within are stored in a shared memory block. This constrains storable values to only the `int`, `float`, `bool`, `str` (less than 10M bytes each), `bytes` (less than 10M bytes each), and `None` built-in data types. It also notably differs from the built-in `list` type in that these lists can not change their overall length (i.e. no `append`, `insert`, etc.) and do not support the dynamic creation of new **ShareableList** instances via slicing.

*sequence* is used in populating a new **ShareableList** full of values. Set to `None` to instead attach to an already existing **ShareableList** by its unique shared memory name.

*name* is the unique name for the requested shared memory, as described in the definition for **SharedMemory**. When attaching to an existing **ShareableList**, specify its shared memory block's unique name while leaving *sequence* set to `None`.

*count(value)*

Returns the number of occurrences of *value*.

*index(value)*

Returns first index position of *value*. Raises **ValueError** if *value* is not present.

format

Read-only attribute containing the **struct** packing format used by all currently stored values.

shm

The **SharedMemory** instance where the values are stored.

The following example demonstrates basic use of a **ShareableList** instance:

```
>>> from multiprocessing import shared_memory
>>> a = shared_memory.ShareableList(['howdy', b'HoWdY',
>>> [ type(entry) for entry in a ]
[<class 'str'>, <class 'bytes'>, <class 'float'>, <class
>>> a[2]
-273.154
>>> a[2] = -78.5
>>> a[2]
-78.5
>>> a[2] = 'dry ice' # Changing data types is supported
>>> a[2]
'dry ice'
>>> a[2] = 'larger than previously allocated storage spa
Traceback (most recent call last):
...
ValueError: exceeds available storage for existing str
>>> a[2]
'dry ice'
>>> len(a)
7
>>> a.index(42)
6
>>> a.count(b'howdy')
0
>>> a.count(b'HoWdY')
1
>>> a.shm.close()
```

```
>>> a.shm.unlink()
>>> del a # Use of a ShareableList after call to unlink
```

The following example depicts how one, two, or many processes may access the same [ShareableList](#) by supplying the name of the shared memory block behind it:

```
>>> b = shared_memory.ShareableList(range(5)) #
>>> c = shared_memory.ShareableList(name=b.shm.name) #
>>> c
ShareableList([0, 1, 2, 3, 4], name='...')
>>> c[-1] = -999
>>> b[-1]
-999
>>> b.shm.close()
>>> c.shm.close()
>>> c.shm.unlink()
```

The following examples demonstrates that `ShareableList` (and underlying `SharedMemory`) objects can be pickled and unpickled if needed. Note, that it will still be the same shared object. This happens, because the deserialized object has the same unique name and is just attached to an existing object with the same name (if the object is still alive):

```
>>> import pickle
>>> from multiprocessing import shared_memory
>>> sl = shared_memory.ShareableList(range(10))
>>> list(sl)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]

>>> deserialized_sl = pickle.loads(pickle.dumps(sl))
>>> list(deserialized_sl)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]

>>> sl[0] = -1
>>> deserialized_sl[1] = -2
>>> list(sl)
[-1, -2, 2, 3, 4, 5, 6, 7, 8, 9]
>>> list(deserialized_sl)
```

```
[-1, -2, 2, 3, 4, 5, 6, 7, 8, 9]
```

```
>>> sl.shm.close()
```

```
>>> sl.shm.unlink()
```

# The concurrent package

Currently, there is only one module in this package:

- `concurrent.futures` – Launching parallel tasks

# `concurrent.futures` — Launching parallel tasks

*New in version 3.2.*

**Source code:** [Lib/concurrent/futures/thread.py](https://github.com/python/cpython/tree/3.11/Lib/concurrent/futures/thread.py) [https://github.com/python/cpython/tree/3.11/Lib/concurrent/futures/thread.py] and [Lib/concurrent/futures/process.py](https://github.com/python/cpython/tree/3.11/Lib/concurrent/futures/process.py) [https://github.com/python/cpython/tree/3.11/Lib/concurrent/futures/process.py]

---

The `concurrent.futures` module provides a high-level interface for asynchronously executing callables.

The asynchronous execution can be performed with threads, using `ThreadPoolExecutor`, or separate processes, using `ProcessPoolExecutor`. Both implement the same interface, which is defined by the abstract `Executor` class.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

## Executor Objects

`class concurrent.futures.Executor`

An abstract class that provides methods to execute calls asynchronously. It should not be used directly, but through its concrete subclasses.

`submit(fn, /, *args, **kwargs)`

Schedules the callable, `fn`, to be  
executed as `fn(*args, **kwargs)`

and returns a **Future** object representing the execution of the callable.

```
with ThreadPoolExecutor(max_workers=1) as executor:
    future = executor.submit(pow, 323, 12)
    print(future.result())
```

`map(func, *iterables, timeout=None, chunksize=1)`

Similar to `map(func, *iterables)` except:

- the *iterables* are collected immediately rather than lazily;
- *func* is executed asynchronously and several calls to *func* may be made concurrently.

The returned iterator raises a **TimeoutError** if `__next__()` is called and the result isn't available after *timeout* seconds from the original call to `Executor.map()`. *timeout* can be an int or a float. If *timeout* is not specified or `None`, there is no limit to the wait time.

If a *func* call raises an exception, then that exception will be raised when its value is retrieved from the iterator.

When using **ProcessPoolExecutor**, this method chops *iterables* into a number of chunks which it submits to the pool as separate tasks. The (approximate) size of these chunks can be specified by setting *chunksize* to a positive integer. For very long iterables, using a large value for

*chunksize* can significantly improve performance compared to the default size of 1. With `ThreadPoolExecutor`, *chunksize* has no effect.

*Changed in version 3.5:* Added the *chunksize* argument.

`shutdown(wait = True, *,  
cancel_futures = False)`

Signal the executor that it should free any resources that it is using when the currently pending futures are done executing. Calls to `Executor.submit()` and `Executor.map()` made after shutdown will raise `RuntimeError`.

If *wait* is `True` then this method will not return until all the pending futures are done executing and the resources associated with the executor have been freed. If *wait* is `False` then this method will return immediately and the resources associated with the executor will be freed when all pending futures are done executing. Regardless of the value of *wait*, the entire Python program will not exit until all pending futures are done executing.

If *cancel\_futures* is `True`, this method will cancel all pending futures that the executor has not started running. Any futures that are completed or running won't be cancelled, regardless of the value of *cancel\_futures*.

If both *cancel\_futures* and *wait* are `True`, all futures that the executor has started running will be completed prior to this method returning. The remaining futures are cancelled.

You can avoid having to call this method explicitly if you use the `with` statement, which will shutdown the `Executor` (waiting as if `Executor.shutdown()` were called with *wait* set to `True`):

```
import shutil
with ThreadPoolExecutor(max_workers=4) as e:
    e.submit(shutil.copy, 'src1.txt', 'dest1.txt')
    e.submit(shutil.copy, 'src2.txt', 'dest2.txt')
    e.submit(shutil.copy, 'src3.txt', 'dest3.txt')
    e.submit(shutil.copy, 'src4.txt', 'dest4.txt')
```

*Changed in version 3.9:* Added *cancel\_futures*.

## ThreadPoolExecutor

`ThreadPoolExecutor` is an `Executor` subclass that uses a pool of threads to execute calls asynchronously.

Deadlocks can occur when the callable associated with a `Future` waits on the results of another `Future`. For example:

```
import time
def wait_on_b():
    time.sleep(5)
    print(b.result())  # b will never complete because it
                        # is waiting for itself to complete
    return 5

def wait_on_a():
    time.sleep(5)
```

```
print(a.result()) # a will never complete because i
return 6
```

```
executor = ThreadPoolExecutor(max_workers=2)
a = executor.submit(wait_on_b)
b = executor.submit(wait_on_a)
```

And:

```
def wait_on_future():
    f = executor.submit(pow, 5, 2)
    # This will never complete because there is only one
    # it is executing this function.
    print(f.result())
```

```
executor = ThreadPoolExecutor(max_workers=1)
executor.submit(wait_on_future)
```

*class concurrent.futures.ThreadPoolExecutor(max\_workers=None, thread\_name\_prefix="", initializer=None, initargs=())*

An **Executor** subclass that uses a pool of at most *max\_workers* threads to execute calls asynchronously.

All threads enqueued to `ThreadPoolExecutor` will be joined before the interpreter can exit. Note that the exit handler which does this is executed *before* any exit handlers added using `atexit`. This means exceptions in the main thread must be caught and handled in order to signal threads to exit gracefully. For this reason, it is recommended that `ThreadPoolExecutor` not be used for long-running tasks.

*initializer* is an optional callable that is called at the start of each worker thread; *initargs* is a tuple of arguments passed to the initializer. Should *initializer* raise an exception, all currently pending jobs will raise a **BrokenThreadPool**, as well as any attempt to submit more jobs to the pool.

*Changed in version 3.5:* If *max\_workers* is `None` or not given, it will default to the number of processors on the machine,

multiplied by 5, assuming that `ThreadPoolExecutor` is often used to overlap I/O instead of CPU work and the number of workers should be higher than the number of workers for `ProcessPoolExecutor`.

*New in version 3.6:* The `thread_name_prefix` argument was added to allow users to control the `threading.Thread` names for worker threads created by the pool for easier debugging.

*Changed in version 3.7:* Added the `initializer` and `initargs` arguments.

*Changed in version 3.8:* Default value of `max_workers` is changed to `min(32, os.cpu_count() + 4)`. This default value preserves at least 5 workers for I/O bound tasks. It utilizes at most 32 CPU cores for CPU bound tasks which release the GIL. And it avoids using very large resources implicitly on many-core machines.

`ThreadPoolExecutor` now reuses idle worker threads before starting `max_workers` worker threads too.

## ThreadPoolExecutor Example

```
import concurrent.futures
import urllib.request

URLS = ['http://www.foxnews.com/',
        'http://www.cnn.com/',
        'http://europe.wsj.com/',
        'http://www.bbc.co.uk/',
        'http://nonexistent-subdomain.python.org/']

# Retrieve a single page and report the URL and contents
def load_url(url, timeout):
    with urllib.request.urlopen(url, timeout=timeout) as conn:
        return conn.read()

# We can use a with statement to ensure threads are clean up
```

```

with concurrent.futures.ThreadPoolExecutor(max_workers=5)
    # Start the load operations and mark each future with
    future_to_url = {executor.submit(load_url, url, 60):
                      url for url in urls}
    for future in concurrent.futures.as_completed(future_to_url):
        url = future_to_url[future]
        try:
            data = future.result()
        except Exception as exc:
            print('%r generated an exception: %s' % (url, exc))
        else:
            print('%r page is %d bytes' % (url, len(data)))

```

## ProcessPoolExecutor

The **ProcessPoolExecutor** class is an **Executor** subclass that uses a pool of processes to execute calls asynchronously. **ProcessPoolExecutor** uses the **multiprocessing** module, which allows it to side-step the **Global Interpreter Lock** but also means that only picklable objects can be executed and returned.

The `__main__` module must be importable by worker subprocesses. This means that **ProcessPoolExecutor** will not work in the interactive interpreter.

Calling **Executor** or **Future** methods from a callable submitted to a **ProcessPoolExecutor** will result in deadlock.

```

class concurrent.futures.ProcessPoolExecutor(max_workers=None,
mp_context=None, initializer=None, initargs=(),
max_tasks_per_child=None)

```

An **Executor** subclass that executes calls asynchronously using a pool of at most *max\_workers* processes. If *max\_workers* is `None` or not given, it will default to the number of processors on the machine. If *max\_workers* is less than or equal to 0, then a **ValueError** will be raised. On Windows, *max\_workers* must be less than or equal to 61. If it is not then **ValueError** will be raised. If *max\_workers* is `None`, then the default chosen will be at most 61, even if more processors are available. *mp\_context* can be a multiprocessing context or

None. It will be used to launch the workers. If `mp_context` is None or not given, the default multiprocessing context is used.

*initializer* is an optional callable that is called at the start of each worker process; *initargs* is a tuple of arguments passed to the initializer. Should *initializer* raise an exception, all currently pending jobs will raise a **BrokenProcessPool**, as well as any attempt to submit more jobs to the pool.

*max\_tasks\_per\_child* is an optional argument that specifies the maximum number of tasks a single process can execute before it will exit and be replaced with a fresh worker process. By default *max\_tasks\_per\_child* is None which means worker processes will live as long as the pool. When a max is specified, the “spawn” multiprocessing start method will be used by default in absence of a *mp\_context* parameter. This feature is incompatible with the “fork” start method.

*Changed in version 3.3:* When one of the worker processes terminates abruptly, a **BrokenProcessPool** error is now raised. Previously, behaviour was undefined but operations on the executor or its futures would often freeze or deadlock.

*Changed in version 3.7:* The *mp\_context* argument was added to allow users to control the start\_method for worker processes created by the pool.

Added the *initializer* and *initargs* arguments.

*Changed in version 3.11:* The *max\_tasks\_per\_child* argument was added to allow users to control the lifetime of workers in the pool.

## ProcessPoolExecutor Example

```
import concurrent.futures
import math
```

```
PRIMES = [
```

```
112272535095293,  
112582705942171,  
112272535095293,  
115280095190773,  
115797848077099,  
1099726899285419]
```

```
def is_prime(n):  
    if n < 2:  
        return False  
    if n == 2:  
        return True  
    if n % 2 == 0:  
        return False  
  
    sqrt_n = int(math.floor(math.sqrt(n)))  
    for i in range(3, sqrt_n + 1, 2):  
        if n % i == 0:  
            return False  
    return True  
  
def main():  
    with concurrent.futures.ProcessPoolExecutor() as executor:  
        for number, prime in zip(PRIMES, executor.map(is_prime, PRIMES)):  
            print('%d is prime: %s' % (number, prime))  
  
if __name__ == '__main__':  
    main()
```

## Future Objects

The **Future** class encapsulates the asynchronous execution of a callable. **Future** instances are created by **Executor.submit()**.

*class concurrent.futures.Future*

Encapsulates the asynchronous execution of a callable.

**Future** instances are created by **Executor.submit()** and should not be created directly except for testing.

`cancel()`

Attempt to cancel the call. If the call is currently being executed or finished running and cannot be cancelled then the method will return `False`, otherwise the call will be cancelled and the method will return `True`.

`cancelled()`

Return `True` if the call was successfully cancelled.

`running()`

Return `True` if the call is currently being executed and cannot be cancelled.

`done()`

Return `True` if the call was successfully cancelled or finished running.

`result(timeout=None)`

Return the value returned by the call. If the call hasn't yet completed then this method will wait up to *timeout* seconds. If the call hasn't completed in *timeout* seconds, then a `TimeoutError` will be raised. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

If the future is cancelled before completing then `CancelledError` will be raised.

If the call raised an exception, this

method will raise the same exception.

`exception(timeout=None)`

Return the exception raised by the call. If the call hasn't yet completed then this method will wait up to *timeout* seconds. If the call hasn't completed in *timeout* seconds, then a **TimeoutError** will be raised. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

If the future is cancelled before completing then **CancelledError** will be raised.

If the call completed without raising, `None` is returned.

`add_done_callback(fn)`

Attaches the callable *fn* to the future. *fn* will be called, with the future as its only argument, when the future is cancelled or finishes running.

Added callables are called in the order that they were added and are always called in a thread belonging to the process that added them. If the callable raises an **Exception** subclass, it will be logged and ignored. If the callable raises a **BaseException** subclass, the behavior is undefined.

If the future has already completed or been cancelled, *fn* will be called immediately.

The following **Future** methods are meant for use in unit tests and **Executor** implementations.

#### `set_running_or_notify_cancel()`

This method should only be called by **Executor** implementations before executing the work associated with the **Future** and by unit tests.

If the method returns `False` then the **Future** was cancelled, i.e. **Future.cancel()** was called and returned `True`. Any threads waiting on the **Future** completing (i.e. through **as\_completed()** or **wait()**) will be woken up.

If the method returns `True` then the **Future** was not cancelled and has been put in the running state, i.e. calls to **Future.running()** will return `True`.

This method can only be called once and cannot be called after **Future.set\_result()** or **Future.set\_exception()** have been called.

#### `set_result(result)`

Sets the result of the work associated with the **Future** to *result*.

This method should only be used by **Executor** implementations and unit tests.

*Changed in version 3.8:* This method raises **concurrent.futures.InvalidStateError**

if the **Future** is already done.

`set_exception(exception)`

Sets the result of the work associated with the **Future** to the **Exception** *exception*.

This method should only be used by **Executor** implementations and unit tests.

*Changed in version 3.8:* This method raises **`concurrent.futures.InvalidStateError`** if the **Future** is already done.

## Module Functions

`concurrent.futures.wait(fs, timeout=None, return_when=ALL_COMPLETED)`

Wait for the **Future** instances (possibly created by different **Executor** instances) given by *fs* to complete. Duplicate futures given to *fs* are removed and will be returned only once. Returns a named 2-tuple of sets. The first set, named *done*, contains the futures that completed (finished or cancelled futures) before the wait completed. The second set, named *not\_done*, contains the futures that did not complete (pending or running futures).

*timeout* can be used to control the maximum number of seconds to wait before returning. *timeout* can be an int or float. If *timeout* is not specified or *None*, there is no limit to the wait time.

*return\_when* indicates when this function should return. It must be one of the following constants:

### Description

---

**`ALL_COMPLETED`** Return when any future finishes or is

---

cancelled.

---

**First exception** return when any future finishes by raising an exception. If no future raises an exception then it is equivalent to **ALL\_COMPLETED**.

---

**All completed** return when all futures finish or are cancelled.

---

`concurrent.futures.as_completed(fs, timeout=None)`

Returns an iterator over the **Future** instances (possibly created by different **Executor** instances) given by *fs* that yields futures as they complete (finished or cancelled futures). Any futures given by *fs* that are duplicated will be returned once. Any futures that completed before `as_completed()` is called will be yielded first. The returned iterator raises a **TimeoutError** if `__next__()` is called and the result isn't available after *timeout* seconds from the original call to `as_completed()`. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

See also

**PEP 3148** [<https://peps.python.org/pep-3148/>] – **futures - execute computations asynchronously**

The proposal which described this feature for inclusion in the Python standard library.

## Exception classes

*exception* `concurrent.futures.CancelledError`

Raised when a future is cancelled.

*exception* `concurrent.futures.TimeoutError`

A deprecated alias of **TimeoutError**, raised when a future operation exceeds the given timeout.

*Changed in version 3.11:* This class was made an alias of **TimeoutError**.

*exception* concurrent.futures.BrokenExecutor

Derived from `RuntimeError`, this exception class is raised when an executor is broken for some reason, and cannot be used to submit or execute new tasks.

*New in version 3.7.*

*exception* concurrent.futures.InvalidStateError

Raised when an operation is performed on a future that is not allowed in the current state.

*New in version 3.8.*

*exception* concurrent.futures.thread.BrokenThreadPool

Derived from `BrokenExecutor`, this exception class is raised when one of the workers of a `ThreadPoolExecutor` has failed initializing.

*New in version 3.7.*

*exception* concurrent.futures.process.BrokenProcessPool

Derived from `BrokenExecutor` (formerly `RuntimeError`), this exception class is raised when one of the workers of a `ProcessPoolExecutor` has terminated in a non-clean fashion (for example, if it was killed from the outside).

*New in version 3.3.*

# subprocess — Subprocess management

**Source code:** [Lib/subprocess.py](https://github.com/python/cpython/tree/3.11/Lib/subprocess.py) [https://github.com/python/cpython/tree/3.11/Lib/subprocess.py]

---

The **subprocess** module allows you to spawn new processes, connect to their input/output/error pipes, and obtain their return codes. This module intends to replace several older modules and functions:

```
os.system
os.spawn*
```

Information about how the **subprocess** module can be used to replace these modules and functions can be found in the following sections.

## See also

**PEP 324** [https://peps.python.org/pep-0324/] – PEP proposing the subprocess module

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

## Using the **subprocess** Module

The recommended approach to invoking subprocesses is to use the **run()** function for all use cases it can handle. For more advanced use cases, the underlying **Popen** interface can be used directly.

```
subprocess.run(args, *, stdin=None, input=None, stdout=None,
stderr=None, capture_output=False, shell=False, cwd=None,
timeout=None, check=False, encoding=None, errors=None,
text=None, env=None, universal_newlines=None,
**other_popen_kwargs)
```

Run the command described by *args*. Wait for command to complete, then return a **CompletedProcess** instance.

The arguments shown above are merely the most common ones, described below in **Frequently Used Arguments** (hence the use of keyword-only notation in the abbreviated signature). The full function signature is largely the same as that of the **Popen** constructor - most of the arguments to this function are passed through to that interface. (*timeout*, *input*, *check*, and *capture\_output* are not.)

If *capture\_output* is true, *stdout* and *stderr* will be captured. When used, the internal **Popen** object is automatically created with *stdout*=PIPE and *stderr*=PIPE. The *stdout* and *stderr* arguments may not be supplied at the same time as *capture\_output*. If you wish to capture and combine both streams into one, use *stdout*=PIPE and *stderr*=STDOUT instead of *capture\_output*.

The *timeout* argument is passed to **Popen.communicate()**. If the timeout expires, the child process will be killed and waited for. The **TimeoutExpired** exception will be re-raised after the child process has terminated.

The *input* argument is passed to **Popen.communicate()** and thus to the subprocess's *stdin*. If used it must be a byte sequence, or a string if *encoding* or *errors* is specified or *text* is true. When used, the internal **Popen** object is automatically created with *stdin*=PIPE, and the *stdin* argument may not be used as well.

If *check* is true, and the process exits with a non-zero exit code, a **CalledProcessError** exception will be raised. Attributes of that exception hold the arguments, the exit code, and *stdout* and *stderr* if they were captured.

If *encoding* or *errors* are specified, or *text* is true, file objects for stdin, stdout and stderr are opened in text mode using the specified *encoding* and *errors* or the `io.TextIOWrapper` default. The *universal\_newlines* argument is equivalent to *text* and is provided for backwards compatibility. By default, file objects are opened in binary mode.

If *env* is not `None`, it must be a mapping that defines the environment variables for the new process; these are used instead of the default behavior of inheriting the current process' environment. It is passed directly to `Popen`. This mapping can be str to str on any platform or bytes to bytes on POSIX platforms much like `os.environ` or `os.environb`.

Examples:

```
>>> subprocess.run(["ls", "-l"]) # doesn't capture
CompletedProcess(args=['ls', '-l'], returncode=0)
```

```
>>> subprocess.run("exit 1", shell=True, check=True)
Traceback (most recent call last):
```

```
...
subprocess.CalledProcessError: Command 'exit 1' ret
```

```
>>> subprocess.run(["ls", "-l", "/dev/null"], captu
CompletedProcess(args=['ls', '-l', '/dev/null'], re
stdout=b'crw-rw-rw- 1 root root 1, 3 Jan 23 16:23 /
```

*New in version 3.5.*

*Changed in version 3.6:* Added *encoding* and *errors* parameters

*Changed in version 3.7:* Added the *text* parameter, as a more understandable alias of *universal\_newlines*. Added the *capture\_output* parameter.

*Changed in version 3.11.3:* Changed Windows shell search order for *shell=True*. The current directory and `%PATH%` are replaced with `%COMSPEC%` and `%SystemRoot%\System32\cmd.exe`. As a result, dropping a malicious program named `cmd.exe` into a current directory no longer

works.

*class* subprocess.CompletedProcess

The return value from `run()`, representing a process that has finished.

`args`

The arguments used to launch the process. This may be a list or a string.

`returncode`

Exit status of the child process. Typically, an exit status of 0 indicates that it ran successfully.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

`stdout`

Captured stdout from the child process. A bytes sequence, or a string if `run()` was called with an encoding, errors, or `text=True`. `None` if stdout was not captured.

If you ran the process with `stderr=subprocess.STDOUT`, stdout and stderr will be combined in this attribute, and `stderr` will be `None`.

`stderr`

Captured stderr from the child process. A bytes sequence, or a string if `run()` was called with an encoding, errors, or `text=True`. `None` if stderr was not captured.

`check_returncode()`

If `returncode` is non-zero, raise a `CalledProcessError`.

*New in version 3.5.*

`subprocess.DEVNULL`

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to `Popen` and indicates that the special file `os.devnull` will be used.

*New in version 3.3.*

`subprocess.PIPE`

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to `Popen` and indicates that a pipe to the standard stream should be opened. Most useful with `Popen.communicate()`.

`subprocess.STDOUT`

Special value that can be used as the *stderr* argument to `Popen` and indicates that standard error should go into the same handle as standard output.

*exception* `subprocess.SubprocessError`

Base class for all other exceptions from this module.

*New in version 3.3.*

*exception* `subprocess.TimeoutExpired`

Subclass of `SubprocessError`, raised when a timeout expires while waiting for a child process.

`cmd`

Command that was used to spawn the child process.

`timeout`

Timeout in seconds.

`output`

Output of the child process if it was captured by `run()` or `check_output()`. Otherwise, `None`. This

is always `bytes` when any output was captured regardless of the `text=True` setting. It may remain `None` instead of `b''` when no output was observed.

`stdout`

Alias for output, for symmetry with `stderr`.

`stderr`

Stderr output of the child process if it was captured by `run()`. Otherwise, `None`. This is always `bytes` when stderr output was captured regardless of the `text=True` setting. It may remain `None` instead of `b''` when no stderr output was observed.

*New in version 3.3.*

*Changed in version 3.5: `stdout` and `stderr` attributes added*

*exception* `subprocess.CalledProcessError`

Subclass of `SubprocessError`, raised when a process run by `check_call()`, `check_output()`, or `run()` (with `check=True`) returns a non-zero exit status.

`returncode`

Exit status of the child process. If the process exited due to a signal, this will be the negative signal number.

`cmd`

Command that was used to spawn the child process.

`output`

Output of the child process if it was captured by `run()` or `check_output()`. Otherwise, `None`.

`stdout`

Alias for output, for symmetry with `stderr`.

`stderr`

Stderr output of the child process if it was captured by `run()`. Otherwise, `None`.

*Changed in version 3.5: `stdout` and `stderr` attributes added*

## Frequently Used Arguments

To support a wide variety of use cases, the `Popen` constructor (and the convenience functions) accept a large number of optional arguments. For most typical use cases, many of these arguments can be safely left at their default values. The arguments that are most commonly needed are:

`args` is required for all calls and should be a string, or a sequence of program arguments. Providing a sequence of arguments is generally preferred, as it allows the module to take care of any required escaping and quoting of arguments (e.g. to permit spaces in file names). If passing a single string, either `shell` must be `True` (see below) or else the string must simply name the program to be executed without specifying any arguments.

`stdin`, `stdout` and `stderr` specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are `PIPE`, `DEVNULL`, an existing file descriptor (a positive integer), an existing file object with a valid file descriptor, and `None`. `PIPE` indicates that a new pipe to the child should be created. `DEVNULL` indicates that the special file `os.devnull` will be used. With the default settings of `None`, no redirection will occur; the child's file handles will be inherited from the parent. Additionally, `stderr` can be `STDOUT`, which indicates that the stderr data from the child process should be captured into the same file handle as for `stdout`.

If `encoding` or `errors` are specified, or `text` (also

known as *universal\_newlines*) is true, the file objects *stdin*, *stdout* and *stderr* will be opened in text mode using the *encoding* and *errors* specified in the call or the defaults for `io.TextIOWrapper`.

For *stdin*, line ending characters `'\n'` in the input will be converted to the default line separator `os.linesep`. For *stdout* and *stderr*, all line endings in the output will be converted to `'\n'`. For more information see the documentation of the `io.TextIOWrapper` class when the *newline* argument to its constructor is `None`.

If text mode is not used, *stdin*, *stdout* and *stderr* will be opened as binary streams. No encoding or line ending conversion is performed.

*New in version 3.6:* Added *encoding* and *errors* parameters.

*New in version 3.7:* Added the *text* parameter as an alias for *universal\_newlines*.

## Note

The *newlines* attribute of the file objects `Popen.stdin`, `Popen.stdout` and `Popen.stderr` are not updated by the `Popen.communicate()` method.

If *shell* is `True`, the specified command will be executed through the shell. This can be useful if you are using Python primarily for the enhanced control flow it offers over most system shells and still want convenient access to other shell features such as shell pipes, filename wildcards, environment variable expansion, and expansion of `~` to a user's home directory. However, note that Python itself offers implementations of many shell-like features (in particular, `glob`, `fnmatch`,

`os.walk()`, `os.path.expandvars()`,  
`os.path.expanduser()`, and `shutil`).

*Changed in version 3.3:* When `universal_newlines` is `True`, the class uses the encoding `locale.getpreferredencoding(False)` instead of `locale.getpreferredencoding()`. See the `io.TextIOWrapper` class for more information on this change.

## Note

Read the [Security Considerations](#) section before using `shell=True`.

These options, along with all of the other options, are described in more detail in the [Popen](#) constructor documentation.

## Popen Constructor

The underlying process creation and management in this module is handled by the [Popen](#) class. It offers a lot of flexibility so that developers are able to handle the less common cases not covered by the convenience functions.

```
class subprocess.Popen(args, bufsize = - 1, executable = None,  
stdin = None, stdout = None, stderr = None, preexec_fn = None,  
close_fds = True, shell = False, cwd = None, env = None,  
universal_newlines = None, startupinfo = None, creationflags = 0,  
restore_signals = True, start_new_session = False, pass_fds = (), *,  
group = None, extra_groups = None, user = None, umask = - 1,  
encoding = None, errors = None, text = None, pipesize = - 1,  
process_group = None)
```

Execute a child program in a new process. On POSIX, the class uses `os.execvpe()`-like behavior to execute the child program. On Windows, the class uses the Windows `CreateProcess()` function. The arguments to [Popen](#) are as follows.

*args* should be a sequence of program arguments or else a single string or [path-like object](#). By default, the program to execute is the first item in *args* if *args* is a sequence. If *args* is a string, the interpretation is platform-dependent and described below. See the *shell* and *executable* arguments for additional differences from the default behavior. Unless otherwise stated, it is recommended to pass *args* as a sequence.

## Warning

For maximum reliability, use a fully qualified path for the executable. To search for an unqualified name on **PATH**, use [shutil.which\(\)](#). On all platforms, passing [sys.executable](#) is the recommended way to launch the current Python interpreter again, and use the `-m` command-line format to launch an installed module.

Resolving the path of *executable* (or the first item of *args*) is platform dependent. For POSIX, see [os.execvpe\(\)](#), and note that when resolving or searching for the executable path, *cwd* overrides the current working directory and *env* can override the `PATH` environment variable. For Windows, see the documentation of the `lpApplicationName` and `lpCommandLine` parameters of `WinAPI CreateProcess`, and note that when resolving or searching for the executable path with `shell=False`, *cwd* does not override the current working directory and *env* cannot override the `PATH` environment variable. Using a full path avoids all of these variations.

An example of passing some arguments to an external program as a sequence is:

```
Popen(["/usr/bin/git", "commit", "-m", "Fixes a bug
```

On POSIX, if *args* is a string, the string is interpreted as the name or path of the program to execute. However, this can only be done if not passing arguments to the program.

## Note

It may not be obvious how to break a shell command into a sequence of arguments, especially in complex cases. [shlex.split\(\)](#) can illustrate how to determine the correct tokenization for *args*:

```
>>> import shlex, subprocess
>>> command_line = input()
/bin/vikings -input eggs.txt -output "spam spam.tx
>>> args = shlex.split(command_line)
>>> print(args)
['/bin/vikings', '-input', 'eggs.txt', '-output',
>>> p = subprocess.Popen(args) # Success!
```

Note in particular that options (such as *-input*) and arguments (such as *eggs.txt*) that are separated by whitespace in the shell go in separate list elements, while arguments that need quoting or backslash escaping when used in the shell (such as filenames containing spaces or the *echo* command shown above) are single list elements.

On Windows, if *args* is a sequence, it will be converted to a string in a manner described in [Converting an argument sequence to a string on Windows](#). This is because the underlying `CreateProcess()` operates on strings.

*Changed in version 3.6:* *args* parameter accepts a [path-like object](#) if *shell* is `False` and a sequence containing path-like objects on POSIX.

*Changed in version 3.8:* *args* parameter accepts a [path-like object](#) if *shell* is `False` and a sequence containing bytes and path-like objects on Windows.

The *shell* argument (which defaults to `False`) specifies whether to use the shell as the program to execute. If *shell* is `True`, it is recommended to pass *args* as a string rather than as a sequence.

On POSIX with `shell=True`, the shell defaults to `/bin/sh`. If *args* is a string, the string specifies the command to

execute through the shell. This means that the string must be formatted exactly as it would be when typed at the shell prompt. This includes, for example, quoting or backslash escaping filenames with spaces in them. If *args* is a sequence, the first item specifies the command string, and any additional items will be treated as additional arguments to the shell itself. That is to say, `Popen` does the equivalent of:

```
Popen(['/bin/sh', '-c', args[0], args[1], ...])
```

On Windows with `shell=True`, the **COMSPEC** environment variable specifies the default shell. The only time you need to specify `shell=True` on Windows is when the command you wish to execute is built into the shell (e.g. **dir** or **copy**). You do not need `shell=True` to run a batch file or console-based executable.

### Note

Read the [Security Considerations](#) section before using `shell=True`.

*bufsize* will be supplied as the corresponding argument to the `open()` function when creating the stdin/stdout/stderr pipe file objects:

- **0** means unbuffered (read and write are one system call and can return short)
- **1** means line buffered (only usable if `text=True` or `universal_newlines=True`)
- any other positive value means use a buffer of approximately that size
- negative *bufsize* (the default) means the system default of `io.DEFAULT_BUFFER_SIZE` will be used.

*Changed in version 3.3.1:* *bufsize* now defaults to -1 to enable buffering by default to match the behavior that most code expects. In versions prior to Python 3.2.4 and 3.3.1 it incorrectly defaulted to **0** which was unbuffered and allowed short reads. This was unintentional and did not match the behavior of Python 2 as most code expected.

The *executable* argument specifies a replacement program to execute. It is very seldom needed. When `shell=False`, *executable* replaces the program to execute specified by *args*. However, the original *args* is still passed to the program. Most programs treat the program specified by *args* as the command name, which can then be different from the program actually executed. On POSIX, the *args* name becomes the display name for the executable in utilities such as **ps**. If `shell=True`, on POSIX the *executable* argument specifies a replacement shell for the default `/bin/sh`.

*Changed in version 3.6:* *executable* parameter accepts a [path-like object](#) on POSIX.

*Changed in version 3.8:* *executable* parameter accepts a bytes and [path-like object](#) on Windows.

*Changed in version 3.11.3:* Changed Windows shell search order for `shell=True`. The current directory and `%PATH%` are replaced with `%COMSPEC%` and `%SystemRoot%\System32\cmd.exe`. As a result, dropping a malicious program named `cmd.exe` into a current directory no longer works.

*stdin*, *stdout* and *stderr* specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are **PIPE**, **DEVNULL**, an existing file descriptor (a positive integer), an existing [file object](#) with a valid file descriptor, and `None`. **PIPE** indicates that a new pipe to the child should be created. **DEVNULL** indicates that the special file `os.devnull` will be used. With the default settings of `None`, no redirection will occur; the child's file handles will be inherited from the parent. Additionally, *stderr* can be **STDOUT**, which indicates that the *stderr* data from the applications should be captured into the same file handle as for *stdout*.

If *preexec\_fn* is set to a callable object, this object will be called in the child process just before the child is executed. (POSIX only)

## Warning

The *preexec\_fn* parameter is NOT SAFE to use in the presence of threads in your application. The child process could deadlock before `exec` is called.

## Note

If you need to modify the environment for the child use the *env* parameter rather than doing it in a *preexec\_fn*. The *start\_new\_session* and *process\_group* parameters should take the place of code using *preexec\_fn* to call `os.setsid()` or `os.setpgid()` in the child.

*Changed in version 3.8:* The *preexec\_fn* parameter is no longer supported in subinterpreters. The use of the parameter in a subinterpreter raises `RuntimeError`. The new restriction may affect applications that are deployed in `mod_wsgi`, `uWSGI`, and other embedded environments.

If *close\_fds* is true, all file descriptors except `0`, `1` and `2` will be closed before the child process is executed. Otherwise when *close\_fds* is false, file descriptors obey their inheritable flag as described in [Inheritance of File Descriptors](#).

On Windows, if *close\_fds* is true then no handles will be inherited by the child process unless explicitly passed in the *handle\_list* element of `STARTUPINFO.lpAttributeList`, or by standard handle redirection.

*Changed in version 3.2:* The default for *close\_fds* was changed from `False` to what is described above.

*Changed in version 3.7:* On Windows the default for *close\_fds* was changed from `False` to `True` when redirecting the standard handles. It's now possible to set *close\_fds* to `True` when redirecting the standard handles.

*pass\_fds* is an optional sequence of file descriptors to keep open between the parent and child. Providing any *pass\_fds*

forces *close\_fds* to be **True**. (POSIX only)

*Changed in version 3.2:* The *pass\_fds* parameter was added.

If *cwd* is not `None`, the function changes the working directory to *cwd* before executing the child. *cwd* can be a string, bytes or [path-like](#) object. On POSIX, the function looks for *executable* (or for the first item in *args*) relative to *cwd* if the executable path is a relative path.

*Changed in version 3.6:* *cwd* parameter accepts a [path-like object](#) on POSIX.

*Changed in version 3.7:* *cwd* parameter accepts a [path-like object](#) on Windows.

*Changed in version 3.8:* *cwd* parameter accepts a bytes object on Windows.

If *restore\_signals* is true (the default) all signals that Python has set to `SIG_IGN` are restored to `SIG_DFL` in the child process before the exec. Currently this includes the `SIGPIPE`, `SIGXFZ` and `SIGXFSZ` signals. (POSIX only)

*Changed in version 3.2:* *restore\_signals* was added.

If *start\_new\_session* is true the `setsid()` system call will be made in the child process prior to the execution of the subprocess.

[Availability](#): POSIX

*Changed in version 3.2:* *start\_new\_session* was added.

If *process\_group* is a non-negative integer, the `setpgid(0, value)` system call will be made in the child process prior to the execution of the subprocess.

[Availability](#): POSIX

*Changed in version 3.11:* *process\_group* was added.

If *group* is not `None`, the `setregid()` system call will be made in the child process prior to the execution of the subprocess. If the provided value is a string, it will be looked up via `grp.getgrnam()` and the value in `gr_gid` will be used. If the value is an integer, it will be passed verbatim. (POSIX only)

**Availability:** POSIX

*New in version 3.9.*

If *extra\_groups* is not `None`, the `setgroups()` system call will be made in the child process prior to the execution of the subprocess. Strings provided in *extra\_groups* will be looked up via `grp.getgrnam()` and the values in `gr_gid` will be used. Integer values will be passed verbatim. (POSIX only)

**Availability:** POSIX

*New in version 3.9.*

If *user* is not `None`, the `setreuid()` system call will be made in the child process prior to the execution of the subprocess. If the provided value is a string, it will be looked up via `pwd.getpwnam()` and the value in `pw_uid` will be used. If the value is an integer, it will be passed verbatim. (POSIX only)

**Availability:** POSIX

*New in version 3.9.*

If *umask* is not negative, the `umask()` system call will be made in the child process prior to the execution of the subprocess.

**Availability:** POSIX

*New in version 3.9.*

If *env* is not `None`, it must be a mapping that defines the environment variables for the new process; these are used instead of the default behavior of inheriting the current

process' environment. This mapping can be str to str on any platform or bytes to bytes on POSIX platforms much like `os.environ` or `os.environb`.

## Note

If specified, `env` must provide any variables required for the program to execute. On Windows, in order to run a [side-by-side assembly](https://en.wikipedia.org/wiki/Side-by-Side_Assembly) [https://en.wikipedia.org/wiki/Side-by-Side\_Assembly] the specified `env` **must** include a valid `SystemRoot`.

If `encoding` or `errors` are specified, or `text` is true, the file objects `stdin`, `stdout` and `stderr` are opened in text mode with the specified `encoding` and `errors`, as described above in [Frequently Used Arguments](#). The `universal_newlines` argument is equivalent to `text` and is provided for backwards compatibility. By default, file objects are opened in binary mode.

*New in version 3.6: `encoding` and `errors` were added.*

*New in version 3.7: `text` was added as a more readable alias for `universal_newlines`.*

If given, `startupinfo` will be a `STARTUPINFO` object, which is passed to the underlying `CreateProcess` function. `creationflags`, if given, can be one or more of the following flags:

- `CREATE_NEW_CONSOLE`
- `CREATE_NEW_PROCESS_GROUP`
- `ABOVE_NORMAL_PRIORITY_CLASS`
- `BELOW_NORMAL_PRIORITY_CLASS`
- `HIGH_PRIORITY_CLASS`
- `IDLE_PRIORITY_CLASS`
- `NORMAL_PRIORITY_CLASS`
- `REALTIME_PRIORITY_CLASS`
- `CREATE_NO_WINDOW`
- `DETACHED_PROCESS`
- `CREATE_DEFAULT_ERROR_MODE`

- `CREATE_BREAKAWAY_FROM_JOB`

`pipesize` can be used to change the size of the pipe when `PIPE` is used for `stdin`, `stdout` or `stderr`. The size of the pipe is only changed on platforms that support this (only Linux at this time of writing). Other platforms will ignore this parameter.

*New in version 3.10:* The `pipesize` parameter was added.

Popen objects are supported as context managers via the `with` statement: on exit, standard file descriptors are closed, and the process is waited for.

```
with Popen(["ifconfig"], stdout=PIPE) as proc:  
    log.write(proc.stdout.read())
```

Popen and the other functions in this module that use it raise an `auditing event` subprocess.Popen with arguments `executable`, `args`, `cwd`, and `env`. The value for `args` may be a single string or a list of strings, depending on platform.

*Changed in version 3.2:* Added context manager support.

*Changed in version 3.6:* Popen destructor now emits a `ResourceWarning` warning if the child process is still running.

*Changed in version 3.8:* Popen can use `os.posix_spawn()` in some cases for better performance. On Windows Subsystem for Linux and QEMU User Emulation, Popen constructor using `os.posix_spawn()` no longer raise an exception on errors like missing program, but the child process fails with a non-zero `returncode`.

## Exceptions

Exceptions raised in the child process, before the new program has started to execute, will be re-raised in the parent.

The most common exception raised is `OSError`. This occurs, for example, when trying to execute a non-existent file. Applications should prepare for `OSError` exceptions. Note that, when `shell=True`, `OSError` will be raised by the child only if the selected shell itself was not found. To determine if the shell failed to find the requested application, it is necessary to check the return code or output from the subprocess.

A `ValueError` will be raised if `Popen` is called with invalid arguments.

`check_call()` and `check_output()` will raise `CalledProcessError` if the called process returns a non-zero return code.

All of the functions and methods that accept a *timeout* parameter, such as `call()` and `Popen.communicate()` will raise `TimeoutExpired` if the timeout expires before the process exits.

Exceptions defined in this module all inherit from `SubprocessError`.

*New in version 3.3:* The `SubprocessError` base class was added.

## Security Considerations

Unlike some other `popen` functions, this implementation will never implicitly call a system shell. This means that all characters, including shell metacharacters, can safely be passed to child processes. If the shell is invoked explicitly, via `shell=True`, it is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid [shell injection](https://en.wikipedia.org/wiki/Shell_injection#Shell_injection) vulnerabilities. On [some platforms](#), it is possible to use `shlex.quote()` for this escaping.

## Popen Objects

Instances of the `Popen` class have the following methods:

## `Popen.poll()`

Check if child process has terminated. Set and return `returncode` attribute. Otherwise, returns `None`.

## `Popen.wait(timeout=None)`

Wait for child process to terminate. Set and return `returncode` attribute.

If the process does not terminate after *timeout* seconds, raise a `TimeoutExpired` exception. It is safe to catch this exception and retry the wait.

### Note

This will deadlock when using `stdout=PIPE` or `stderr=PIPE` and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use `Popen.communicate()` when using pipes to avoid that.

### Note

The function is implemented using a busy loop (non-blocking call and short sleeps). Use the `asyncio` module for an asynchronous wait: see `asyncio.create_subprocess_exec`.

*Changed in version 3.3: timeout was added.*

## `Popen.communicate(input=None, timeout=None)`

Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate and set the `returncode` attribute. The optional *input* argument should be data to be sent to the child process, or `None`, if no data should be sent to the child. If streams were opened in text mode, *input* must be a string. Otherwise, it must be bytes.

`communicate()` returns a tuple `(stdout_data, stderr_data)`. The data will be strings if streams were opened in text mode; otherwise, bytes.

Note that if you want to send data to the process's stdin, you need to create the `Popen` object with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, you need to give `stdout=PIPE` and/or `stderr=PIPE` too.

If the process does not terminate after *timeout* seconds, a **TimeoutExpired** exception will be raised. Catching this exception and retrying communication will not lose any output.

The child process is not killed if the timeout expires, so in order to cleanup properly a well-behaved application should kill the child process and finish communication:

```
proc = subprocess.Popen(...)
try:
    outs, errs = proc.communicate(timeout=15)
except TimeoutExpired:
    proc.kill()
    outs, errs = proc.communicate()
```

### Note

The data read is buffered in memory, so do not use this method if the data size is large or unlimited.

*Changed in version 3.3: timeout was added.*

`Popen.send_signal(signal)`

Sends the signal *signal* to the child.

Do nothing if the process completed.

### Note

On Windows, SIGTERM is an alias for `terminate()`. CTRL\_C\_EVENT and CTRL\_BREAK\_EVENT can be sent to processes started with a *creationflags* parameter which includes `CREATE_NEW_PROCESS_GROUP`.

### Popen.terminate()

Stop the child. On POSIX OSs the method sends SIGTERM to the child. On Windows the Win32 API function **TerminateProcess()** is called to stop the child.

### Popen.kill()

Kills the child. On POSIX OSs the function sends SIGKILL to the child. On Windows `kill()` is an alias for `terminate()`.

The following attributes are also set by the class for you to access. Reassigning them to new values is unsupported:

### Popen.args

The *args* argument as it was passed to **Popen** – a sequence of program arguments or else a single string.

*New in version 3.3.*

### Popen.stdin

If the *stdin* argument was **PIPE**, this attribute is a writeable stream object as returned by `open()`. If the *encoding* or *errors* arguments were specified or the *text* or *universal\_newlines* argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the *stdin* argument was not **PIPE**, this attribute is `None`.

### Popen.stdout

If the *stdout* argument was **PIPE**, this attribute is a readable stream object as returned by `open()`. Reading from the stream provides output from the child process. If the *encoding* or *errors* arguments were specified or the *text* or

`universal_newlines` argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the `stdout` argument was not `PIPE`, this attribute is `None`.

### `Popen.stderr`

If the `stderr` argument was `PIPE`, this attribute is a readable stream object as returned by `open()`. Reading from the stream provides error output from the child process. If the `encoding` or `errors` arguments were specified or the `text` or `universal_newlines` argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the `stderr` argument was not `PIPE`, this attribute is `None`.

### Warning

Use `communicate()` rather than `.stdin.write`, `.stdout.read` or `.stderr.read` to avoid deadlocks due to any of the other OS pipe buffers filling up and blocking the child process.

### `Popen.pid`

The process ID of the child process.

Note that if you set the `shell` argument to `True`, this is the process ID of the spawned shell.

### `Popen.returncode`

The child return code. Initially `None`, `returncode` is set by a call to the `poll()`, `wait()`, or `communicate()` methods if they detect that the process has terminated.

A `None` value indicates that the process hadn't yet terminated at the time of the last method call.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

## Windows Popen Helpers

The **STARTUPINFO** class and following constants are only available on Windows.

```
class subprocess.STARTUPINFO(*, dwFlags=0, hStdInput=None,
hStdOutput=None, hStdError=None, wShowWindow=0,
lpAttributeList=None)
```

Partial support of the Windows **STARTUPINFO** [[https://msdn.microsoft.com/en-us/library/ms686331\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/ms686331(v=vs.85).aspx)] structure is used for **Popen** creation. The following attributes can be set by passing them as keyword-only arguments.

*Changed in version 3.7:* Keyword-only argument support was added.

### dwFlags

A bit field that determines whether certain **STARTUPINFO** attributes are used when the process creates a window.

```
si = subprocess.STARTUPINFO()
si.dwFlags = subprocess.STARTF_USESTDHANDLES |
```

### hStdInput

If **dwFlags** specifies **STARTF\_USESTDHANDLES**, this attribute is the standard input handle for the process. If **STARTF\_USESTDHANDLES** is not specified, the default for standard input is the keyboard buffer.

### hStdOutput

If **dwFlags** specifies **STARTF\_USESTDHANDLES**, this attribute is the standard output handle for the process. Otherwise, this attribute is ignored and the default for standard output is the console window's buffer.

### hStdError

If **dwFlags** specifies **STARTF\_USESTDHANDLES**, this attribute is the standard error handle for the process. Otherwise, this attribute is ignored and the default for standard error is the console window's buffer.

## wShowWindow

If **dwFlags** specifies **STARTF\_USESHOWWINDOW**, this attribute can be any of the values that can be specified in the `nCmdShow` parameter for the **ShowWindow** [[https://msdn.microsoft.com/en-us/library/ms633548\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/ms633548(v=vs.85).aspx)] function, except for **SW\_SHOWDEFAULT**. Otherwise, this attribute is ignored.

**SW\_HIDE** is provided for this attribute. It is used when **Popen** is called with `shell=True`.

## lpAttributeList

A dictionary of additional attributes for process creation as given in `STARTUPINFOEX`, see **UpdateProcThreadAttribute** [[https://msdn.microsoft.com/en-us/library/windows/desktop/ms686880\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/windows/desktop/ms686880(v=vs.85).aspx)].

Supported attributes:

### **handle\_list**

Sequence of handles that will be inherited.  
*close\_fds* must be true if non-empty.

The handles must be temporarily made inheritable by **os.set\_handle\_inheritable()** when passed to the **Popen** constructor, else **OSError** will be raised with Windows error `ERROR_INVALID_PARAMETER (87)`.

### **Warning**

In a multithreaded process, use caution to avoid leaking handles that are marked inheritable when combining this feature with concurrent calls to other process creation functions that inherit all handles such as **os.system()**. This also applies to standard handle redirection, which temporarily creates inheritable handles.

*New in version 3.7.*

## Windows Constants

The **subprocess** module exposes the following constants.

**subprocess.STD\_INPUT\_HANDLE**

The standard input device. Initially, this is the console input buffer, `CONIN$`.

**subprocess.STD\_OUTPUT\_HANDLE**

The standard output device. Initially, this is the active console screen buffer, `CONOUT$`.

**subprocess.STD\_ERROR\_HANDLE**

The standard error device. Initially, this is the active console screen buffer, `CONOUT$`.

**subprocess.SW\_HIDE**

Hides the window. Another window will be activated.

**subprocess.STARTF\_USESTDHANDLES**

Specifies that the **STARTUPINFO.hStdInput**, **STARTUPINFO.hStdOutput**, and **STARTUPINFO.hStdError** attributes contain additional information.

**subprocess.STARTF\_USESHOWWINDOW**

Specifies that the **STARTUPINFO.wShowWindow** attribute contains additional information.

**subprocess.CREATE\_NEW\_CONSOLE**

The new process has a new console, instead of inheriting its parent's console (the default).

**subprocess.CREATE\_NEW\_PROCESS\_GROUP**

A **Popen** `creationflags` parameter to specify that a new process group will be created. This flag is necessary for using `os.kill()` on the subprocess.

This flag is ignored if `CREATE_NEW_CONSOLE` is specified.

`subprocess.ABOVE_NORMAL_PRIORITY_CLASS`

A **Popen** `creationflags` parameter to specify that a new process will have an above average priority.

*New in version 3.7.*

`subprocess.BELOW_NORMAL_PRIORITY_CLASS`

A **Popen** `creationflags` parameter to specify that a new process will have a below average priority.

*New in version 3.7.*

`subprocess.HIGH_PRIORITY_CLASS`

A **Popen** `creationflags` parameter to specify that a new process will have a high priority.

*New in version 3.7.*

`subprocess.IDLE_PRIORITY_CLASS`

A **Popen** `creationflags` parameter to specify that a new process will have an idle (lowest) priority.

*New in version 3.7.*

`subprocess.NORMAL_PRIORITY_CLASS`

A **Popen** `creationflags` parameter to specify that a new process will have a normal priority. (default)

*New in version 3.7.*

`subprocess.REALTIME_PRIORITY_CLASS`

A **Popen** `creationflags` parameter to specify that a new process will have realtime priority. You should almost never

use `REALTIME_PRIORITY_CLASS`, because this interrupts system threads that manage mouse input, keyboard input, and background disk flushing. This class can be appropriate for applications that “talk” directly to hardware or that perform brief tasks that should have limited interruptions.

*New in version 3.7.*

`subprocess.CREATE_NO_WINDOW`

A **Popen** `creationflags` parameter to specify that a new process will not create a window.

*New in version 3.7.*

`subprocess.DETACHED_PROCESS`

A **Popen** `creationflags` parameter to specify that a new process will not inherit its parent’s console. This value cannot be used with `CREATE_NEW_CONSOLE`.

*New in version 3.7.*

`subprocess.CREATE_DEFAULT_ERROR_MODE`

A **Popen** `creationflags` parameter to specify that a new process does not inherit the error mode of the calling process. Instead, the new process gets the default error mode. This feature is particularly useful for multithreaded shell applications that run with hard errors disabled.

*New in version 3.7.*

`subprocess.CREATE_BREAKAWAY_FROM_JOB`

A **Popen** `creationflags` parameter to specify that a new process is not associated with the job.

*New in version 3.7.*

## Older high-level API

Prior to Python 3.5, these three functions comprised the high level

API to subprocess. You can now use `run()` in many cases, but lots of existing code calls these functions.

```
subprocess.call(args, *, stdin=None, stdout=None, stderr=None,  
shell=False, cwd=None, timeout=None, **other_popen_kwargs)
```

Run the command described by `args`. Wait for command to complete, then return the `returncode` attribute.

Code needing to capture stdout or stderr should use `run()` instead:

```
run(...).returncode
```

To suppress stdout or stderr, supply a value of `DEVNULL`.

The arguments shown above are merely some common ones. The full function signature is the same as that of the `Popen` constructor - this function passes all supplied arguments other than `timeout` directly through to that interface.

### Note

Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

*Changed in version 3.3: `timeout` was added.*

*Changed in version 3.11.3:* Changed Windows shell search order for `shell=True`. The current directory and `%PATH%` are replaced with `%COMSPEC%` and `%SystemRoot%\System32\cmd.exe`. As a result, dropping a malicious program named `cmd.exe` into a current directory no longer works.

```
subprocess.check_call(args, *, stdin=None, stdout=None,  
stderr=None, shell=False, cwd=None, timeout=None,  
**other_popen_kwargs)
```

Run command with arguments. Wait for command to complete. If the return code was zero then return, otherwise raise `CalledProcessError`. The `CalledProcessError` object will have the return code in the `returncode` attribute. If `check_call()` was unable to start the process it will propagate the exception that was raised.

Code needing to capture stdout or stderr should use `run()` instead:

```
run(..., check=True)
```

To suppress stdout or stderr, supply a value of `DEVNULL`.

The arguments shown above are merely some common ones. The full function signature is the same as that of the `Popen` constructor - this function passes all supplied arguments other than `timeout` directly through to that interface.

### Note

Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

*Changed in version 3.3: `timeout` was added.*

*Changed in version 3.11.3:* Changed Windows shell search order for `shell=True`. The current directory and `%PATH%` are replaced with `%COMSPEC%` and `%SystemRoot%\System32\cmd.exe`. As a result, dropping a malicious program named `cmd.exe` into a current directory no longer works.

```
subprocess.check_output(args, *, stdin=None, stderr=None,
shell=False, cwd=None, encoding=None, errors=None,
universal_newlines=None, timeout=None, text=None,
**other_popen_kwargs)
```

Run command with arguments and return its output.

If the return code was non-zero it raises a `CalledProcessError`. The `CalledProcessError` object will have the return code in the `returncode` attribute and any output in the `output` attribute.

This is equivalent to:

```
run(..., check=True, stdout=PIPE).stdout
```

The arguments shown above are merely some common ones. The full function signature is largely the same as that of `run()` - most arguments are passed directly through to that interface. One API deviation from `run()` behavior exists: passing `input=None` will behave the same as `input=b''` (or `input=''`, depending on other arguments) rather than using the parent's standard input file handle.

By default, this function will return the data as encoded bytes. The actual encoding of the output data may depend on the command being invoked, so the decoding to text will often need to be handled at the application level.

This behaviour may be overridden by setting *text*, *encoding*, *errors*, or *universal\_newlines* to `True` as described in [Frequently Used Arguments](#) and `run()`.

To also capture standard error in the result, use `stderr=subprocess.STDOUT`:

```
>>> subprocess.check_output(
...     "ls non_existent_file; exit 0",
...     stderr=subprocess.STDOUT,
...     shell=True)
'ls: non_existent_file: No such file or directory\n'
```

*New in version 3.1.*

*Changed in version 3.3:* `timeout` was added.

*Changed in version 3.4:* Support for the *input* keyword argument was added.

*Changed in version 3.6:* `encoding` and `errors` were added. See [run\(\)](#) for details.

*New in version 3.7:* `text` was added as a more readable alias for `universal_newlines`.

*Changed in version 3.11.3:* Changed Windows shell search order for `shell=True`. The current directory and `%PATH%` are replaced with `%COMSPEC%` and `%SystemRoot%\System32\cmd.exe`. As a result, dropping a malicious program named `cmd.exe` into a current directory no longer works.

## Replacing Older Functions with the `subprocess` Module

In this section, “a becomes b” means that b can be used as a replacement for a.

### Note

All “a” functions in this section fail (more or less) silently if the executed program cannot be found; the “b” replacements raise `OSError` instead.

In addition, the replacements using `check_output()` will fail with a `CalledProcessError` if the requested operation produces a non-zero return code. The output is still available as the `output` attribute of the raised exception.

In the following examples, we assume that the relevant functions have already been imported from the `subprocess` module.

### Replacing `/bin/sh` shell command substitution

```
output=$(mycmd myarg)
```

becomes:

```
output = check_output(["mycmd", "myarg"])
```

## Replacing shell pipeline

```
output=$(dmesg | grep hda)
```

becomes:

```
p1 = Popen(["dmesg"], stdout=PIPE)
p2 = Popen(["grep", "hda"], stdin=p1.stdout, stdout=PIPE)
p1.stdout.close() # Allow p1 to receive a SIGPIPE if p2
output = p2.communicate()[0]
```

The `p1.stdout.close()` call after starting the `p2` is important in order for `p1` to receive a `SIGPIPE` if `p2` exits before `p1`.

Alternatively, for trusted input, the shell's own pipeline support may still be used directly:

```
output=$(dmesg | grep hda)
```

becomes:

```
output = check_output("dmesg | grep hda", shell=True)
```

## Replacing `os.system()`

```
sts = os.system("mycmd" + " myarg")
# becomes
retcode = call("mycmd" + " myarg", shell=True)
```

Notes:

- Calling the program through the shell is usually not required.
- The `call()` return value is encoded differently to that of `os.system()`.
- The `os.system()` function ignores `SIGINT` and `SIGQUIT` signals while the command is running, but the caller must do this separately when using the `subprocess` module.

A more realistic example would look like this:

```

try:
    retcode = call("mycmd" + " myarg", shell=True)
    if retcode < 0:
        print("Child was terminated by signal", -retcode)
    else:
        print("Child returned", retcode, file=sys.stderr)
except OSError as e:
    print("Execution failed:", e, file=sys.stderr)

```

## Replacing the `os.spawn` family

P\_NOWAIT example:

```

pid = os.spawnlp(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg")
==>
pid = Popen(["/bin/mycmd", "myarg"]).pid

```

P\_WAIT example:

```

retcode = os.spawnlp(os.P_WAIT, "/bin/mycmd", "mycmd", "myarg")
==>
retcode = call(["/bin/mycmd", "myarg"])

```

Vector example:

```

os.spawnvp(os.P_NOWAIT, path, args)
==>
Popen([path] + args[1:])

```

Environment example:

```

os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg", env)
==>
Popen(["/bin/mycmd", "myarg"], env={"PATH": "/usr/bin"})

```

## Replacing `os.popen()`, `os.popen2()`, `os.popen3()`

```

(child_stdin, child_stdout) = os.popen2(cmd, mode, bufsize)
==>

```

```

p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdin, child_stdout) = (p.stdin, p.stdout)

(child_stdin,
 child_stdout,
 child_stderr) = os.popen3(cmd, mode, bufsize)
==>
p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=PIPE, close_fds=True)
(child_stdin,
 child_stdout,
 child_stderr) = (p.stdin, p.stdout, p.stderr)

(child_stdin, child_stdout_and_stderr) = os.popen4(cmd,
==>
p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=STDOUT, close_fds=True)
(child_stdin, child_stdout_and_stderr) = (p.stdin, p.stdout_and_stderr)

```

Return code handling translates as follows:

```

pipe = os.popen(cmd, 'w')
...
rc = pipe.close()
if rc is not None and rc >> 8:
    print("There were some errors")
==>
process = Popen(cmd, stdin=PIPE)
...
process.stdin.close()
if process.wait() != 0:
    print("There were some errors")

```

## Replacing functions from the `popen2` module

### Note

If the `cmd` argument to `popen2` functions is a string, the

command is executed through `/bin/sh`. If it is a list, the command is directly executed.

```
(child_stdout, child_stdin) = popen2.popen2("somestring")
==>
p = Popen("somestring", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)

(child_stdout, child_stdin) = popen2.popen2(["mycmd", "n
==>
p = Popen(["mycmd", "myarg"], bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

**`popen2.Popen3`** and **`popen2.Popen4`** basically work as **`subprocess.Popen`**, except that:

- **`Popen`** raises an exception if the execution fails.
- The *`capturestderr`* argument is replaced with the *`stderr`* argument.
- `stdin=PIPE` and `stdout=PIPE` must be specified.
- `popen2` closes all file descriptors by default, but you have to specify `close_fds=True` with **`Popen`** to guarantee this behavior on all platforms or past Python versions.

## Legacy Shell Invocation Functions

This module also provides the following legacy functions from the `2.x commands` module. These operations implicitly invoke the system shell and none of the guarantees described above regarding security and exception handling consistency are valid for these functions.

**`subprocess.getstatusoutput(cmd, *, encoding=None, errors=None)`**  
Return `(exitcode, output)` of executing *cmd* in a shell.

Execute the string *cmd* in a shell with  
**`Popen.check_output()`** and return a 2-tuple

(`exitcode`, `output`). *encoding* and *errors* are used to decode output; see the notes on [Frequently Used Arguments](#) for more details.

A trailing newline is stripped from the output. The exit code for the command can be interpreted as the return code of `subprocess`. Example:

```
>>> subprocess.getstatusoutput('ls /bin/ls')
(0, '/bin/ls')
>>> subprocess.getstatusoutput('cat /bin/junk')
(1, 'cat: /bin/junk: No such file or directory')
>>> subprocess.getstatusoutput('/bin/junk')
(127, 'sh: /bin/junk: not found')
>>> subprocess.getstatusoutput('/bin/kill $$')
(-15, '')
```

**Availability:** Unix, Windows.

*Changed in version 3.3.4:* Windows support was added.

The function now returns (`exitcode`, `output`) instead of (`status`, `output`) as it did in Python 3.3.3 and earlier. `exitcode` has the same value as [returncode](#).

*New in version 3.11:* Added *encoding* and *errors* arguments.

`subprocess.getoutput(cmd, *, encoding=None, errors=None)`

Return output (stdout and stderr) of executing *cmd* in a shell.

Like [getstatusoutput\(\)](#), except the exit code is ignored and the return value is a string containing the command's output. Example:

```
>>> subprocess.getoutput('ls /bin/ls')
'/bin/ls'
```

**Availability:** Unix, Windows.

*Changed in version 3.3.4:* Windows support added

*New in version 3.11: Added `encoding` and `errors` arguments.*

## Notes

### Converting an argument sequence to a string on Windows

On Windows, an *args* sequence is converted to a string that can be parsed using the following rules (which correspond to the rules used by the MS C runtime):

1. Arguments are delimited by white space, which is either a space or a tab.
2. A string surrounded by double quotation marks is interpreted as a single argument, regardless of white space contained within. A quoted string can be embedded in an argument.
3. A double quotation mark preceded by a backslash is interpreted as a literal double quotation mark.
4. Backslashes are interpreted literally, unless they immediately precede a double quotation mark.
5. If backslashes immediately precede a double quotation mark, every pair of backslashes is interpreted as a literal backslash. If the number of backslashes is odd, the last backslash escapes the next double quotation mark as described in rule 3.

See also

#### **shlex**

Module which provides function to parse and escape command lines.

### Disabling use of `vfork()` or `posix_spawn()`

On Linux, **subprocess** defaults to using the `vfork()` system call internally when it is safe to do so rather than `fork()`. This greatly improves performance.

If you ever encounter a presumed highly unusual situation where

you need to prevent `vfork()` from being used by Python, you can set the **`subprocess._USE_VFORK`** attribute to a false value.

```
subprocess._USE_VFORK = False # See CPython issue gh-NM
```

Setting this has no impact on use of `posix_spawn()` which could use `vfork()` internally within its libc implementation. There is a similar **`subprocess._USE_POSIX_SPAWN`** attribute if you need to prevent use of that.

```
subprocess._USE_POSIX_SPAWN = False # See CPython issue
```

It is safe to set these to false on any Python version. They will have no effect on older versions when unsupported. Do not assume the attributes are available to read. Despite their names, a true value does not indicate that the corresponding function will be used, only that it may be.

Please file issues any time you have to use these private knobs with a way to reproduce the issue you were seeing. Link to that issue from a comment in your code.

*New in version 3.8:* `_USE_POSIX_SPAWN`

*New in version 3.11:* `_USE_VFORK`

# **sched** — Event scheduler

**Source code:** [Lib/sched.py](https://github.com/python/cpython/tree/3.11/Lib/sched.py) [https://github.com/python/cpython/tree/3.11/Lib/sched.py]

---

The **sched** module defines a class which implements a general purpose event scheduler:

```
class sched.scheduler(timefunc = time.monotonic,  
delayfunc = time.sleep)
```

The **scheduler** class defines a generic interface to scheduling events. It needs two functions to actually deal with the “outside world” — *timefunc* should be callable without arguments, and return a number (the “time”, in any units whatsoever). The *delayfunc* function should be callable with one argument, compatible with the output of *timefunc*, and should delay that many time units. *delayfunc* will also be called with the argument 0 after each event is run to allow other threads an opportunity to run in multi-threaded applications.

*Changed in version 3.3:* *timefunc* and *delayfunc* parameters are optional.

*Changed in version 3.3:* **scheduler** class can be safely used in multi-threaded environments.

Example:

```
>>> import sched, time  
>>> s = sched.scheduler(time.monotonic, time.sleep)  
>>> def print_time(a='default'):  
...     print("From print_time", time.time(), a)  
...  
>>> def print_some_times():
```

```

...     print(time.time())
...     s.enter(10, 1, print_time)
...     s.enter(5, 2, print_time, argument=('positional', 'keyword'))
...     # despite having higher priority, 'keyword' runs first
...     s.enter(5, 1, print_time, kwargs={'a': 'keyword'})
...     s.enterabs(1_650_000_000, 10, print_time, argument='positional')
...     s.enterabs(1_650_000_000, 5, print_time, argument='keyword')
...     s.run()
...     print(time.time())
...
>>> print_some_times()
1652342830.3640375
From print_time 1652342830.3642538 second enterabs
From print_time 1652342830.3643398 first enterabs
From print_time 1652342835.3694863 positional
From print_time 1652342835.3696074 keyword
From print_time 1652342840.369612 default
1652342840.3697174

```

## Scheduler Objects

**scheduler** instances have the following methods and attributes:

**scheduler.enterabs(*time*, *priority*, *action*, *argument*=(), *kwargs*={})**

Schedule a new event. The *time* argument should be a numeric type compatible with the return value of the *timefunc* function passed to the constructor. Events scheduled for the same *time* will be executed in the order of their *priority*. A lower number represents a higher priority.

Executing the event means executing `action(*argument, **kwargs)`. *argument* is a sequence holding the positional arguments for *action*. *kwargs* is a dictionary holding the keyword arguments for *action*.

Return value is an event which may be used for later cancellation of the event (see **cancel()**).

*Changed in version 3.3: argument parameter is optional.*

*Changed in version 3.3: kwargs parameter was added.*

`scheduler.enter(delay, priority, action, argument=(), kwargs={})`

Schedule an event for *delay* more time units. Other than the relative time, the other arguments, the effect and the return value are the same as those for `enterabs()`.

*Changed in version 3.3: argument parameter is optional.*

*Changed in version 3.3: kwargs parameter was added.*

`scheduler.cancel(event)`

Remove the event from the queue. If *event* is not an event currently in the queue, this method will raise a `ValueError`.

`scheduler.empty()`

Return `True` if the event queue is empty.

`scheduler.run(blocking=True)`

Run all scheduled events. This method will wait (using the `delayfunc()` function passed to the constructor) for the next event, then execute it and so on until there are no more scheduled events.

If *blocking* is false executes the scheduled events due to expire soonest (if any) and then return the deadline of the next scheduled call in the scheduler (if any).

Either *action* or *delayfunc* can raise an exception. In either case, the scheduler will maintain a consistent state and propagate the exception. If an exception is raised by *action*, the event will not be attempted in future calls to `run()`.

If a sequence of events takes longer to run than the time available before the next event, the scheduler will simply fall behind. No events will be dropped; the calling code is responsible for canceling events which are no longer pertinent.

*Changed in version 3.3: blocking* parameter was added.

`scheduler.queue`

Read-only attribute returning a list of upcoming events in the order they will be run. Each event is shown as a [named tuple](#) with the following fields: time, priority, action, argument, kwargs.

# queue — A synchronized queue class

**Source code:** [Lib/queue.py](#) [<https://github.com/python/cpython/tree/3.11/Lib/queue.py>]

---

The **queue** module implements multi-producer, multi-consumer queues. It is especially useful in threaded programming when information must be exchanged safely between multiple threads. The **Queue** class in this module implements all the required locking semantics.

The module implements three types of queue, which differ only in the order in which the entries are retrieved. In a FIFO queue, the first tasks added are the first retrieved. In a LIFO queue, the most recently added entry is the first retrieved (operating like a stack). With a priority queue, the entries are kept sorted (using the **heapq** module) and the lowest valued entry is retrieved first.

Internally, those three types of queues use locks to temporarily block competing threads; however, they are not designed to handle reentrancy within a thread.

In addition, the module implements a “simple” FIFO queue type, **SimpleQueue**, whose specific implementation provides additional guarantees in exchange for the smaller functionality.

The **queue** module defines the following classes and exceptions:

`class queue.Queue(maxsize=0)`

Constructor for a FIFO queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

`class queue.LifoQueue(maxsize=0)`

Constructor for a LIFO queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

`class queue.PriorityQueue(maxsize=0)`

Constructor for a priority queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

The lowest valued entries are retrieved first (the lowest valued entry is the one that would be returned by `min(entries)`). A typical pattern for entries is a tuple in the form: `(priority_number, data)`.

If the *data* elements are not comparable, the data can be wrapped in a class that ignores the data item and only compares the priority number:

```
from dataclasses import dataclass, field
from typing import Any
```

```
@dataclass(order=True)
class PrioritizedItem:
    priority: int
    item: Any=field(compare=False)
```

`class queue.SimpleQueue`

Constructor for an unbounded FIFO queue. Simple queues lack advanced functionality such as task tracking.

*New in version 3.7.*

`exception queue.Empty`

Exception raised when non-blocking `get()` (or

`get_nowait()` is called on a `Queue` object which is empty.

*exception queue.Full*

Exception raised when non-blocking `put()` (or `put_nowait()`) is called on a `Queue` object which is full.

## Queue Objects

Queue objects (`Queue`, `LifoQueue`, or `PriorityQueue`) provide the public methods described below.

`Queue.qsize()`

Return the approximate size of the queue. Note, `qsize() > 0` doesn't guarantee that a subsequent `get()` will not block, nor will `qsize() < maxsize` guarantee that `put()` will not block.

`Queue.empty()`

Return `True` if the queue is empty, `False` otherwise. If `empty()` returns `True` it doesn't guarantee that a subsequent call to `put()` will not block. Similarly, if `empty()` returns `False` it doesn't guarantee that a subsequent call to `get()` will not block.

`Queue.full()`

Return `True` if the queue is full, `False` otherwise. If `full()` returns `True` it doesn't guarantee that a subsequent call to `get()` will not block. Similarly, if `full()` returns `False` it doesn't guarantee that a subsequent call to `put()` will not block.

`Queue.put(item, block=True, timeout=None)`

Put *item* into the queue. If optional args *block* is true and *timeout* is `None` (the default), block if necessary until a free slot is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the `Full` exception if no free slot was available within that time. Otherwise (*block* is false), put an item on the queue if a free slot is immediately

available, else raise the `Full` exception (*timeout* is ignored in that case).

`Queue.put_nowait(item)`

Equivalent to `put(item, block=False)`.

`Queue.get(block=True, timeout=None)`

Remove and return an item from the queue. If optional args *block* is true and *timeout* is `None` (the default), block if necessary until an item is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the `Empty` exception if no item was available within that time. Otherwise (*block* is false), return an item if one is immediately available, else raise the `Empty` exception (*timeout* is ignored in that case).

Prior to 3.0 on POSIX systems, and for all versions on Windows, if *block* is true and *timeout* is `None`, this operation goes into an uninterruptible wait on an underlying lock. This means that no exceptions can occur, and in particular a `SIGINT` will not trigger a `KeyboardInterrupt`.

`Queue.get_nowait()`

Equivalent to `get(False)`.

Two methods are offered to support tracking whether enqueued tasks have been fully processed by daemon consumer threads.

`Queue.task_done()`

Indicate that a formerly enqueued task is complete. Used by queue consumer threads. For each `get()` used to fetch a task, a subsequent call to `task_done()` tells the queue that the processing on the task is complete.

If a `join()` is currently blocking, it will resume when all items have been processed (meaning that a `task_done()` call was received for every item that had been `put()` into the queue).

Raises a **ValueError** if called more times than there were items placed in the queue.

### Queue.join()

Blocks until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls **task\_done()** to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, **join()** unblocks.

Example of how to wait for enqueued tasks to be completed:

```
import threading
import queue

q = queue.Queue()

def worker():
    while True:
        item = q.get()
        print(f'Working on {item}')
        print(f'Finished {item}')
        q.task_done()

# Turn-on the worker thread.
threading.Thread(target=worker, daemon=True).start()

# Send thirty task requests to the worker.
for item in range(30):
    q.put(item)

# Block until all tasks are done.
q.join()
print('All work completed')
```

# SimpleQueue Objects

**SimpleQueue** objects provide the public methods described below.

## `SimpleQueue.qsize()`

Return the approximate size of the queue. Note, `qsize() > 0` doesn't guarantee that a subsequent `get()` will not block.

## `SimpleQueue.empty()`

Return `True` if the queue is empty, `False` otherwise. If `empty()` returns `False` it doesn't guarantee that a subsequent call to `get()` will not block.

## `SimpleQueue.put(item, block=True, timeout=None)`

Put *item* into the queue. The method never blocks and always succeeds (except for potential low-level errors such as failure to allocate memory). The optional args *block* and *timeout* are ignored and only provided for compatibility with **`Queue.put()`**.

**CPython implementation detail:** This method has a C implementation which is reentrant. That is, a `put()` or `get()` call can be interrupted by another `put()` call in the same thread without deadlocking or corrupting internal state inside the queue. This makes it appropriate for use in destructors such as `__del__` methods or **`weakref`** callbacks.

## `SimpleQueue.put_nowait(item)`

Equivalent to `put(item, block=False)`, provided for compatibility with **`Queue.put_nowait()`**.

## `SimpleQueue.get(block=True, timeout=None)`

Remove and return an item from the queue. If optional args *block* is true and *timeout* is `None` (the default), block if necessary until an item is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the

**Empty** exception if no item was available within that time. Otherwise (*block* is false), return an item if one is immediately available, else raise the **Empty** exception (*timeout* is ignored in that case).

`SimpleQueue.get_nowait()`

Equivalent to `get(False)`.

## See also

**Class** `multiprocessing.Queue`

A queue class for use in a multi-processing (rather than multi-threading) context.

`collections.deque` is an alternative implementation of unbounded queues with fast atomic `append()` and `popleft()` operations that do not require locking and also support indexing.

# contextvars — Context Variables

---

This module provides APIs to manage, store, and access context-local state. The `ContextVar` class is used to declare and work with *Context Variables*. The `copy_context()` function and the `Context` class should be used to manage the current context in asynchronous frameworks.

Context managers that have state should use Context Variables instead of `threading.local()` to prevent their state from bleeding to other code unexpectedly, when used in concurrent code.

See also [PEP 567](https://peps.python.org/pep-0567/) [https://peps.python.org/pep-0567/] for additional details.

*New in version 3.7.*

## Context Variables

`class contextvars.ContextVar(name[, *, default])`

This class is used to declare a new Context Variable, e.g.:

```
var: ContextVar[int] = ContextVar('var', default=42)
```

The required *name* parameter is used for introspection and debug purposes.

The optional keyword-only *default* parameter is returned by `ContextVar.get()` when no value for the variable is found in the current context.

**Important:** Context Variables should be created at the top module level and never in closures. `Context` objects hold

strong references to context variables which prevents context variables from being properly garbage collected.

`name`

The name of the variable. This is a read-only property.

*New in version 3.7.1.*

`get([default])`

Return a value for the context variable for the current context.

If there is no value for the variable in the current context, the method will:

- return the value of the *default* argument of the method, if provided; or
- return the default value for the context variable, if it was created with one; or
- raise a **LookupError**.

`set(value)`

Call to set a new value for the context variable in the current context.

The required *value* argument is the new value for the context variable.

Returns a **Token** object that can be used to restore the variable to its previous value via the **ContextVar.reset()** method.

`reset(token)`

Reset the context variable to the value it had before the **ContextVar.set()** that created the *token* was used.

For example:

```
var = ContextVar('var')
```

```
token = var.set('new value')
# code that uses 'var'; var.get() returns 'new'
var.reset(token)

# After the reset call the var has no value again
# var.get() would raise a LookupError.
```

*class* contextvars.Token

*Token* objects are returned by the `ContextVar.set()` method. They can be passed to the `ContextVar.reset()` method to revert the value of the variable to what it was before the corresponding *set*.

*var*

A read-only property. Points to the `ContextVar` object that created the token.

*old\_value*

A read-only property. Set to the value the variable had before the `ContextVar.set()` method call that created the token. It points to `Token.MISSING` if the variable was not set before the call.

*MISSING*

A marker object used by `Token.old_value`.

## Manual Context Management

contextvars.copy\_context()

Returns a copy of the current `Context` object.

The following snippet gets a copy of the current context and prints all variables and their values that are set in it:

```
ctx: Context = copy_context()
print(list(ctx.items()))
```

The function has an  $O(1)$  complexity, i.e. works equally fast for contexts with a few context variables and for contexts that have a lot of them.

*class* contextvars.Context

A mapping of `ContextVars` to their values.

`Context()` creates an empty context with no values in it. To get a copy of the current context use the `copy_context()` function.

Every thread will have a different top-level `Context` object. This means that a `ContextVar` object behaves in a similar fashion to `threading.local()` when values are assigned in different threads.

Context implements the `collections.abc.Mapping` interface.

`run(callable, *args, **kwargs)`

Execute `callable(*args, **kwargs)` code in the context object the `run` method is called on. Return the result of the execution or propagate an exception if one occurred.

Any changes to any context variables that *callable* makes will be contained in the context object:

```
var = ContextVar('var')
var.set('spam')
```

```
def main():
    # 'var' was set to 'spam' before
    # calling 'copy_context()' and 'ctx.run(main)'
    # var.get() == ctx[var] == 'spam'

    var.set('ham')

    # Now, after setting 'var' to 'ham':
    # var.get() == ctx[var] == 'ham'
```

```

ctx = copy_context()

# Any changes that the 'main' function makes to
# will be contained in 'ctx'.
ctx.run(main)

# The 'main()' function was run in the 'ctx' co
# so changes to 'var' are contained in it:
# ctx[var] == 'ham'

# However, outside of 'ctx', 'var' is still set
# var.get() == 'spam'

```

The method raises a **RuntimeError** when called on the same context object from more than one OS thread, or when called recursively.

## copy()

Return a shallow copy of the context object.

## var in context

Return `True` if the *context* has a value for *var* set;  
return `False` otherwise.

## context[var]

Return the value of the *var* **ContextVar** variable. If the variable is not set in the context object, a **KeyError** is raised.

## get(var[, default])

Return the value for *var* if *var* has the value in the context object. Return *default* otherwise. If *default* is not given, return `None`.

## iter(context)

Return an iterator over the variables stored in the

context object.

`len(proxy)`

Return the number of variables set in the context object.

`keys()`

Return a list of all variables in the context object.

`values()`

Return a list of all variables' values in the context object.

`items()`

Return a list of 2-tuples containing all variables and their values in the context object.

## asyncio support

Context variables are natively supported in [asyncio](#) and are ready to be used without any extra configuration. For example, here is a simple echo server, that uses a context variable to make the address of a remote client available in the Task that handles that client:

```
import asyncio
import contextvars

client_addr_var = contextvars.ContextVar('client_addr')

def render_goodbye():
    # The address of the currently handled client can be
    # without passing it explicitly to this function.

    client_addr = client_addr_var.get()
    return f'Good bye, client @ {client_addr}\n'.encode()

async def handle_request(reader, writer):
```

```
addr = writer.transport.get_extra_info('socket').getsockname()
client_addr_var.set(addr)

# In any code that we call is now possible to get
# client's address by calling 'client_addr_var.get()'

while True:
    line = await reader.readline()
    print(line)
    if not line.strip():
        break
    writer.write(line)

writer.write(render_goodbye())
writer.close()

async def main():
    srv = await asyncio.start_server(
        handle_request, '127.0.0.1', 8081)

    async with srv:
        await srv.serve_forever()

asyncio.run(main())

# To test it you can use telnet:
# telnet 127.0.0.1 8081
```

# `_thread` — Low-level threading API

---

This module provides low-level primitives for working with multiple threads (also called *light-weight processes* or *tasks*) — multiple threads of control sharing their global data space. For synchronization, simple locks (also called *mutexes* or *binary semaphores*) are provided. The `threading` module provides an easier to use and higher-level threading API built on top of this module.

*Changed in version 3.7:* This module used to be optional, it is now always available.

This module defines the following constants and functions:

*exception* `_thread.error`

Raised on thread-specific errors.

*Changed in version 3.3:* This is now a synonym of the built-in `RuntimeError`.

`_thread.LockType`

This is the type of lock objects.

`_thread.start_new_thread(function, args[, kwargs])`

Start a new thread and return its identifier. The thread executes the function *function* with the argument list *args* (which must be a tuple). The optional *kwargs* argument specifies a dictionary of keyword arguments.

When the function returns, the thread silently exits.

When the function terminates with an unhandled exception,

`sys.unraisablehook()` is called to handle the exception. The *object* attribute of the hook argument is *function*. By default, a stack trace is printed and then the thread exits (but other threads continue to run).

When the function raises a `SystemExit` exception, it is silently ignored.

*Changed in version 3.8:* `sys.unraisablehook()` is now used to handle unhandled exceptions.

`_thread.interrupt_main(signum = signal.SIGINT, /)`

Simulate the effect of a signal arriving in the main thread. A thread can use this function to interrupt the main thread, though there is no guarantee that the interruption will happen immediately.

If given, *signum* is the number of the signal to simulate. If *signum* is not given, `signal.SIGINT` is simulated.

If the given signal isn't handled by Python (it was set to `signal.SIG_DFL` or `signal.SIG_IGN`), this function does nothing.

*Changed in version 3.10:* The *signum* argument is added to customize the signal number.

### Note

This does not emit the corresponding signal but schedules a call to the associated handler (if it exists). If you want to truly emit the signal, use `signal.raise_signal()`.

`_thread.exit()`

Raise the `SystemExit` exception. When not caught, this will cause the thread to exit silently.

`_thread.allocate_lock()`

Return a new lock object. Methods of locks are described below. The lock is initially unlocked.

### `_thread.get_ident()`

Return the ‘thread identifier’ of the current thread. This is a nonzero integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

### `_thread.get_native_id()`

Return the native integral Thread ID of the current thread assigned by the kernel. This is a non-negative integer. Its value may be used to uniquely identify this particular thread system-wide (until the thread terminates, after which the value may be recycled by the OS).

**Availability:** Windows, FreeBSD, Linux, macOS, OpenBSD, NetBSD, AIX.

*New in version 3.8.*

### `_thread.stack_size([size])`

Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, a **RuntimeError** is raised. If the specified stack size is invalid, a **ValueError** is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples

of 4096 for the stack size is the suggested approach in the absence of more specific information).

**Availability:** Windows, pthreads.

Unix platforms with POSIX threads support.

`_thread.TIMEOUT_MAX`

The maximum value allowed for the *timeout* parameter of **Lock.acquire()**. Specifying a timeout greater than this value will raise an **OverflowError**.

*New in version 3.2.*

Lock objects have the following methods:

`lock.acquire(blocking=True, timeout=-1)`

Without any optional argument, this method acquires the lock unconditionally, if necessary waiting until it is released by another thread (only one thread at a time can acquire a lock — that’s their reason for existence).

If the *blocking* argument is present, the action depends on its value: if it is `False`, the lock is only acquired if it can be acquired immediately without waiting, while if it is `True`, the lock is acquired unconditionally as above.

If the floating-point *timeout* argument is present and positive, it specifies the maximum wait time in seconds before returning. A negative *timeout* argument specifies an unbounded wait. You cannot specify a *timeout* if *blocking* is `False`.

The return value is `True` if the lock is acquired successfully, `False` if not.

*Changed in version 3.2:* The *timeout* parameter is new.

*Changed in version 3.2:* Lock acquires can now be interrupted by signals on POSIX.

`lock.release()`

Releases the lock. The lock must have been acquired earlier, but not necessarily by the same thread.

`lock.locked()`

Return the status of the lock: `True` if it has been acquired by some thread, `False` if not.

In addition to these methods, lock objects can also be used via the `with` statement, e.g.:

```
import _thread

a_lock = _thread.allocate_lock()

with a_lock:
    print("a_lock is locked while this executes")
```

### Caveats:

- Threads interact strangely with interrupts: the `KeyboardInterrupt` exception will be received by an arbitrary thread. (When the `signal` module is available, interrupts always go to the main thread.)
- Calling `sys.exit()` or raising the `SystemExit` exception is equivalent to calling `_thread.exit()`.
- It is not possible to interrupt the `acquire()` method on a lock — the `KeyboardInterrupt` exception will happen after the lock has been acquired.
- When the main thread exits, it is system defined whether the other threads survive. On most systems, they are killed without executing `try ... finally` clauses or executing object destructors.
- When the main thread exits, it does not do any of its usual cleanup (except that `try ... finally` clauses are honored), and the standard I/O files are not flushed.

# Networking and Interprocess Communication

The modules described in this chapter provide mechanisms for networking and inter-processes communication.

Some modules only work for two processes that are on the same machine, e.g. `signal` and `mmap`. Other modules support networking protocols that two or more processes can use to communicate across machines.

The list of modules described in this chapter is:

- `asyncio` — Asynchronous I/O
- `socket` — Low-level networking interface
- `ssl` — TLS/SSL wrapper for socket objects
- `select` — Waiting for I/O completion
- `selectors` — High-level I/O multiplexing
- `signal` — Set handlers for asynchronous events
- `mmap` — Memory-mapped file support

# asyncio — Asynchronous I/O

---

## Hello World!

```
import asyncio

async def main():
    print('Hello ...')
    await asyncio.sleep(1)
    print('... World!')

asyncio.run(main())
```

asyncio is a library to write **concurrent** code using the **async/await** syntax.

asyncio is used as a foundation for multiple Python asynchronous frameworks that provide high-performance network and web-servers, database connection libraries, distributed task queues, etc.

asyncio is often a perfect fit for IO-bound and high-level **structured** network code.

asyncio provides a set of **high-level** APIs to:

- [run Python coroutines](#) concurrently and have full control over their execution;
- perform [network IO and IPC](#);
- control [subprocesses](#);
- distribute tasks via [queues](#);
- [synchronize](#) concurrent code;

Additionally, there are **low-level** APIs for *library and framework developers* to:

- create and manage [event loops](#), which provide asynchronous

APIs for [networking](#), running [subprocesses](#), handling [OS signals](#), etc;

- implement efficient protocols using [transports](#);
- [bridge](#) callback-based libraries and code with `async/await` syntax.

You can experiment with an `asyncio` concurrent context in the REPL:

```
$ python -m asyncio
asyncio REPL ...
Use "await" directly instead of "asyncio.run()".
Type "help", "copyright", "credits" or "license" for more
>>> import asyncio
>>> await asyncio.sleep(10, result='hello')
'hello'
```

[Availability](#): not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscrip`ten and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

The source code for asyncio can be found in [Lib/asyncio/](#) [<https://github.com/python/cpython/tree/3.11/Lib/asyncio/>].

# Runners

**Source code:** [Lib/asyncio/runners.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/runners.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/runners.py]

This section outlines high-level asyncio primitives to run asyncio code.

They are built on top of an [event loop](#) with the aim to simplify async code usage for common wide-spread scenarios.

- [Running an asyncio Program](#)
- [Runner context manager](#)
- [Handling Keyboard Interruption](#)

## Running an asyncio Program

`asyncio.run(coro, *, debug=None)`

Execute the [coroutine](#) *coro* and return the result.

This function runs the passed coroutine, taking care of managing the asyncio event loop, *finalizing asynchronous generators*, and closing the threadpool.

This function cannot be called when another asyncio event loop is running in the same thread.

If *debug* is `True`, the event loop will be run in debug mode. `False` disables debug mode explicitly. `None` is used to respect the global [Debug Mode](#) settings.

This function always creates a new event loop and closes it at the end. It should be used as a main entry point for asyncio programs, and should ideally only be called once.

Example:

```
async def main():
    await asyncio.sleep(1)
    print('hello')
```

```
asyncio.run(main())
```

*New in version 3.7.*

*Changed in version 3.9:* Updated to use `loop.shutdown_default_executor()`.

*Changed in version 3.10:* `debug` is `None` by default to respect the global debug mode settings.

## Runner context manager

`class asyncio.Runner(*, debug=None, loop_factory=None)`

A context manager that simplifies *multiple* async function calls in the same context.

Sometimes several top-level async functions should be called in the same `event loop` and `contextvars.Context`.

If `debug` is `True`, the event loop will be run in debug mode. `False` disables debug mode explicitly. `None` is used to respect the global `Debug Mode` settings.

`loop_factory` could be used for overriding the loop creation. It is the responsibility of the `loop_factory` to set the created loop as the current one. By default `asyncio.new_event_loop()` is used and set as current event loop with `asyncio.set_event_loop()` if `loop_factory` is `None`.

Basically, `asyncio.run()` example can be rewritten with the runner usage:

```
async def main():
    await asyncio.sleep(1)
    print('hello')
```

```
with asyncio.Runner() as runner:
    runner.run(main())
```

*New in version 3.11.*

`run(coro, *, context=None)`

Run a [coroutine](#) `coro` in the embedded loop.

Return the coroutine's result or raise its exception.

An optional keyword-only *context* argument allows specifying a custom [contextvars.Context](#) for the `coro` to run in. The runner's default context is used if `None`.

This function cannot be called when another `asyncio` event loop is running in the same thread.

`close()`

Close the runner.

Finalize asynchronous generators, shutdown default executor, close the event loop and release embedded [contextvars.Context](#).

`get_loop()`

Return the event loop associated with the runner instance.

### Note

[Runner](#) uses the lazy initialization strategy, its constructor doesn't initialize underlying low-level structures.

Embedded *loop* and *context* are created at the `with` body entering or the first call of `run()` or `get_loop()`.

# Handling Keyboard Interruption

*New in version 3.11.*

When `signal.SIGINT` is raised by `Ctrl-C`, `KeyboardInterrupt` exception is raised in the main thread by default. However this doesn't work with `asyncio` because it can interrupt asyncio internals and can hang the program from exiting.

To mitigate this issue, `asyncio` handles `signal.SIGINT` as follows:

1. `asyncio.Runner.run()` installs a custom `signal.SIGINT` handler before any user code is executed and removes it when exiting from the function.
2. The `Runner` creates the main task for the passed coroutine for its execution.
3. When `signal.SIGINT` is raised by `Ctrl-C`, the custom signal handler cancels the main task by calling `asyncio.Task.cancel()` which raises `asyncio.CancelledError` inside the main task. This causes the Python stack to unwind, `try/except` and `try/finally` blocks can be used for resource cleanup. After the main task is cancelled, `asyncio.Runner.run()` raises `KeyboardInterrupt`.
4. A user could write a tight loop which cannot be interrupted by `asyncio.Task.cancel()`, in which case the second following `Ctrl-C` immediately raises the `KeyboardInterrupt` without cancelling the main task.

# Coroutines and Tasks

This section outlines high-level asyncio APIs to work with coroutines and Tasks.

- [Coroutines](#)
- [Awaitables](#)
- [Creating Tasks](#)
- [Task Cancellation](#)
- [Task Groups](#)
- [Sleeping](#)
- [Running Tasks Concurrently](#)
- [Shielding From Cancellation](#)
- [Timeouts](#)
- [Waiting Primitives](#)
- [Running in Threads](#)
- [Scheduling From Other Threads](#)
- [Introspection](#)
- [Task Object](#)

## Coroutines

**Source code:** [Lib/asyncio/coroutines.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/coroutines.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/coroutines.py]

---

[Coroutines](#) declared with the `async/await` syntax is the preferred way of writing asyncio applications. For example, the following snippet of code prints “hello”, waits 1 second, and then prints “world”:

```
>>> import asyncio

>>> async def main():
...     print('hello')
```

```
...     await asyncio.sleep(1)
...     print('world')
```

```
>>> asyncio.run(main())
hello
world
```

Note that simply calling a coroutine will not schedule it to be executed:

```
>>> main()
<coroutine object main at 0x1053bb7c8>
```

To actually run a coroutine, asyncio provides the following mechanisms:

- The `asyncio.run()` function to run the top-level entry point “main()” function (see the above example.)
- Awaiting on a coroutine. The following snippet of code will print “hello” after waiting for 1 second, and then print “world” after waiting for *another* 2 seconds:

```
import asyncio
import time

async def say_after(delay, what):
    await asyncio.sleep(delay)
    print(what)

async def main():
    print(f"started at {time.strftime('%X')}")

    await say_after(1, 'hello')
    await say_after(2, 'world')

    print(f"finished at {time.strftime('%X')}")

asyncio.run(main())
```

Expected output:

```
started at 17:13:52
hello
world
finished at 17:13:55
```

- The `asyncio.create_task()` function to run coroutines concurrently as `asyncio Tasks`.

Let's modify the above example and run two `say_after` coroutines *concurrently*:

```
async def main():
    task1 = asyncio.create_task(
        say_after(1, 'hello'))

    task2 = asyncio.create_task(
        say_after(2, 'world'))

    print(f"started at {time.strftime('%X')}")

    # Wait until both tasks are completed (should t
    # around 2 seconds.)
    await task1
    await task2

    print(f"finished at {time.strftime('%X')}")
```

Note that expected output now shows that the snippet runs 1 second faster than before:

```
started at 17:14:32
hello
world
finished at 17:14:34
```

- The `asyncio.TaskGroup` class provides a more modern alternative to `create_task()`. Using this API, the last example becomes:

```

async def main():
    async with asyncio.TaskGroup() as tg:
        task1 = tg.create_task(
            say_after(1, 'hello'))

        task2 = tg.create_task(
            say_after(2, 'world'))

    print(f"started at {time.strftime('%X')}")

    # The await is implicit when the context manager
    # is finished.

    print(f"finished at {time.strftime('%X')}")

```

The timing and output should be the same as for the previous version.

*New in version 3.11:* [asyncio.TaskGroup](#).

## Awaitables

We say that an object is an **awaitable** object if it can be used in an [await](#) expression. Many asyncio APIs are designed to accept awaitables.

There are three main types of *awaitable* objects: **coroutines**, **Tasks**, and **Futures**.

### Coroutines

Python coroutines are *awaitables* and therefore can be awaited from other coroutines:

```

import asyncio

async def nested():
    return 42

```

```

async def main():
    # Nothing happens if we just call "nested()".
    # A coroutine object is created but not awaited,
    # so it *won't run at all*.
    nested()

    # Let's do it differently now and await it:
    print(await nested()) # will print "42".

asyncio.run(main())

```

## Important

In this documentation the term “coroutine” can be used for two closely related concepts:

- a *coroutine function*: an `async def` function;
- a *coroutine object*: an object returned by calling a *coroutine function*.

## Tasks

*Tasks* are used to schedule coroutines *concurrently*.

When a coroutine is wrapped into a *Task* with functions like `asyncio.create_task()` the coroutine is automatically scheduled to run soon:

```

import asyncio

async def nested():
    return 42

async def main():
    # Schedule nested() to run soon concurrently
    # with "main()".
    task = asyncio.create_task(nested())

```

```
# "task" can now be used to cancel "nested()", or
# can simply be awaited to wait until it is complete
await task
```

```
asyncio.run(main())
```

## Futures

A **Future** is a special **low-level** awaitable object that represents an **eventual result** of an asynchronous operation.

When a Future object is *awaited* it means that the coroutine will wait until the Future is resolved in some other place.

Future objects in asyncio are needed to allow callback-based code to be used with `async/await`.

Normally **there is no need** to create Future objects at the application level code.

Future objects, sometimes exposed by libraries and some asyncio APIs, can be awaited:

```
async def main():
    await function_that_returns_a_future_object()

    # this is also valid:
    await asyncio.gather(
        function_that_returns_a_future_object(),
        some_python_coroutine()
    )
```

A good example of a low-level function that returns a Future object is `loop.run_in_executor()`.

## Creating Tasks

**Source code:** [Lib/asyncio/tasks.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/tasks.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/tasks.py]

---

```
asyncio.create_task(coro, *, name=None, context=None)
```

Wrap the *coro* [coroutine](#) into a [Task](#) and schedule its execution. Return the Task object.

If *name* is not `None`, it is set as the name of the task using [Task.set\\_name\(\)](#).

An optional keyword-only *context* argument allows specifying a custom [contextvars.Context](#) for the *coro* to run in. The current context copy is created when no *context* is provided.

The task is executed in the loop returned by [get\\_running\\_loop\(\)](#), [RuntimeError](#) is raised if there is no running loop in current thread.

### Note

[asyncio.TaskGroup.create\\_task\(\)](#) is a newer alternative that allows for convenient waiting for a group of related tasks.

### Important

Save a reference to the result of this function, to avoid a task disappearing mid-execution. The event loop only keeps weak references to tasks. A task that isn't referenced elsewhere may get garbage collected at any time, even before it's done. For reliable “fire-and-forget” background tasks, gather them in a collection:

```
background_tasks = set()

for i in range(10):
    task = asyncio.create_task(some_coro(param=i))

    # Add task to the set. This creates a strong r
    background_tasks.add(task)
```

```
# To prevent keeping references to finished ta
# make each task remove its own reference from
# completion:
task.add_done_callback(background_tasks.discard)
```

*New in version 3.7.*

*Changed in version 3.8:* Added the *name* parameter.

*Changed in version 3.11:* Added the *context* parameter.

## Task Cancellation

Tasks can easily and safely be cancelled. When a task is cancelled, `asyncio.CancelledError` will be raised in the task at the next opportunity.

It is recommended that coroutines use `try/finally` blocks to robustly perform clean-up logic. In case `asyncio.CancelledError` is explicitly caught, it should generally be propagated when clean-up is complete. `asyncio.CancelledError` directly subclasses `BaseException` so most code will not need to be aware of it.

The `asyncio` components that enable structured concurrency, like `asyncio.TaskGroup` and `asyncio.timeout()`, are implemented using cancellation internally and might misbehave if a coroutine swallows `asyncio.CancelledError`. Similarly, user code should not generally call `uncancel`. However, in cases when suppressing `asyncio.CancelledError` is truly desired, it is necessary to also call `uncancel()` to completely remove the cancellation state.

## Task Groups

Task groups combine a task creation API with a convenient and reliable way to wait for all tasks in the group to finish.

```
class asyncio.TaskGroup
```

An [asynchronous context manager](#) holding a group of tasks. Tasks can be added to the group using `create_task()`. All tasks are awaited when the context manager exits.

*New in version 3.11.*

`create_task(coro, *, name=None, context=None)`

Create a task in this task group. The signature matches that of [asyncio.create\\_task\(\)](#).

Example:

```
async def main():
    async with asyncio.TaskGroup() as tg:
        task1 = tg.create_task(some_coro(...))
        task2 = tg.create_task(another_coro(...))
    print("Both tasks have completed now.")
```

The `async with` statement will wait for all tasks in the group to finish. While waiting, new tasks may still be added to the group (for example, by passing `tg` into one of the coroutines and calling `tg.create_task()` in that coroutine). Once the last task has finished and the `async with` block is exited, no new tasks may be added to the group.

The first time any of the tasks belonging to the group fails with an exception other than [asyncio.CancelledError](#), the remaining tasks in the group are cancelled. No further tasks can then be added to the group. At this point, if the body of the `async with` statement is still active (i.e., `__aexit__()` hasn't been called yet), the task directly containing the `async with` statement is also cancelled. The resulting [asyncio.CancelledError](#) will interrupt an `await`, but it will not bubble out of the containing `async with` statement.

Once all tasks have finished, if any tasks have failed with an exception other than [asyncio.CancelledError](#), those exceptions are combined in an [ExceptionGroup](#) or [BaseExceptionGroup](#) (as appropriate; see their documentation) which is then raised.

Two base exceptions are treated specially: If any task fails with `KeyboardInterrupt` or `SystemExit`, the task group still cancels the remaining tasks and waits for them, but then the initial `KeyboardInterrupt` or `SystemExit` is re-raised instead of `ExceptionGroup` or `BaseExceptionGroup`.

If the body of the `async with` statement exits with an exception (so `__aexit__()` is called with an exception set), this is treated the same as if one of the tasks failed: the remaining tasks are cancelled and then waited for, and non-cancellation exceptions are grouped into an exception group and raised. The exception passed into `__aexit__()`, unless it is `asyncio.CancelledError`, is also included in the exception group. The same special case is made for `KeyboardInterrupt` and `SystemExit` as in the previous paragraph.

## Sleeping

*coroutine* `asyncio.sleep(delay, result=None)`

Block for *delay* seconds.

If *result* is provided, it is returned to the caller when the coroutine completes.

`sleep()` always suspends the current task, allowing other tasks to run.

Setting the delay to 0 provides an optimized path to allow other tasks to run. This can be used by long-running functions to avoid blocking the event loop for the full duration of the function call.

Example of coroutine displaying the current date every second for 5 seconds:

```
import asyncio
import datetime

async def display_date():
    loop = asyncio.get_running_loop()
```

```
end_time = loop.time() + 5.0
while True:
    print(datetime.datetime.now())
    if (loop.time() + 1.0) >= end_time:
        break
    await asyncio.sleep(1)

asyncio.run(display_date())
```

*Changed in version 3.10:* Removed the *loop* parameter.

## Running Tasks Concurrently

*awaitable* `asyncio.gather(*aws, return_exceptions=False)`

Run [awaitable objects](#) in the *aws* sequence *concurrently*.

If any awaitable in *aws* is a coroutine, it is automatically scheduled as a Task.

If all awaitables are completed successfully, the result is an aggregate list of returned values. The order of result values corresponds to the order of awaitables in *aws*.

If *return\_exceptions* is `False` (default), the first raised exception is immediately propagated to the task that awaits on `gather()`. Other awaitables in the *aws* sequence **won't be cancelled** and will continue to run.

If *return\_exceptions* is `True`, exceptions are treated the same as successful results, and aggregated in the result list.

If `gather()` is *cancelled*, all submitted awaitables (that have not completed yet) are also *cancelled*.

If any Task or Future from the *aws* sequence is *cancelled*, it is treated as if it raised [CancelledError](#) – the `gather()` call is **not** cancelled in this case. This is to prevent the cancellation of one submitted Task/Future to cause other Tasks/Futures to be cancelled.

## Note

A more modern way to create and run tasks concurrently and wait for their completion is [asyncio.TaskGroup](#).

### Example:

```
import asyncio

async def factorial(name, number):
    f = 1
    for i in range(2, number + 1):
        print(f"Task {name}: Compute factorial({number})")
        await asyncio.sleep(1)
        f *= i
    print(f"Task {name}: factorial({number}) = {f}")
    return f

async def main():
    # Schedule three calls *concurrently*:
    L = await asyncio.gather(
        factorial("A", 2),
        factorial("B", 3),
        factorial("C", 4),
    )
    print(L)

asyncio.run(main())

# Expected output:
#
# Task A: Compute factorial(2), currently i=2..
# Task B: Compute factorial(3), currently i=2..
# Task C: Compute factorial(4), currently i=2..
# Task A: factorial(2) = 2
# Task B: Compute factorial(3), currently i=3..
# Task C: Compute factorial(4), currently i=3..
# Task B: factorial(3) = 6
# Task C: Compute factorial(4), currently i=4..
```

```
# Task C: factorial(4) = 24
# [2, 6, 24]
```

### Note

If *return\_exceptions* is False, cancelling `gather()` after it has been marked done won't cancel any submitted awaitables. For instance, `gather` can be marked done after propagating an exception to the caller, therefore, calling `gather.cancel()` after catching an exception (raised by one of the awaitables) from `gather` won't cancel any other awaitables.

*Changed in version 3.7:* If the *gather* itself is cancelled, the cancellation is propagated regardless of *return\_exceptions*.

*Changed in version 3.10:* Removed the *loop* parameter.

*Deprecated since version 3.10:* Deprecation warning is emitted if no positional arguments are provided or not all positional arguments are Future-like objects and there is no running event loop.

## Shielding From Cancellation

*awaitable* `asyncio.shield(aw)`

Protect an **awaitable object** from being **cancelled**.

If *aw* is a coroutine it is automatically scheduled as a Task.

The statement:

```
task = asyncio.create_task(something())
res = await shield(task)
```

is equivalent to:

```
res = await something()
```

*except* that if the coroutine containing it is cancelled, the Task

running in `something()` is not cancelled. From the point of view of `something()`, the cancellation did not happen. Although its caller is still cancelled, so the “await” expression still raises a **CancelledError**.

If `something()` is cancelled by other means (i.e. from within itself) that would also cancel `shield()`.

If it is desired to completely ignore cancellation (not recommended) the `shield()` function should be combined with a try/except clause, as follows:

```
task = asyncio.create_task(something())
try:
    res = await shield(task)
except CancellableError:
    res = None
```

### Important

Save a reference to tasks passed to this function, to avoid a task disappearing mid-execution. The event loop only keeps weak references to tasks. A task that isn’t referenced elsewhere may get garbage collected at any time, even before it’s done.

*Changed in version 3.10:* Removed the *loop* parameter.

*Deprecated since version 3.10:* Deprecation warning is emitted if *aw* is not Future-like object and there is no running event loop.

## Timeouts

*coroutine* `asyncio.timeout(delay)`

An **asynchronous context manager** that can be used to limit the amount of time spent waiting on something.

*delay* can either be `None`, or a float/int number of seconds to

wait. If *delay* is `None`, no time limit will be applied; this can be useful if the delay is unknown when the context manager is created.

In either case, the context manager can be rescheduled after creation using `Timeout.reschedule()`.

Example:

```
async def main():
    async with asyncio.timeout(10):
        await long_running_task()
```

If `long_running_task` takes more than 10 seconds to complete, the context manager will cancel the current task and handle the resulting `asyncio.CancelledError` internally, transforming it into a `TimeoutError` which can be caught and handled.

### Note

The `asyncio.timeout()` context manager is what transforms the `asyncio.CancelledError` into a `TimeoutError`, which means the `TimeoutError` can only be caught *outside* of the context manager.

Example of catching `TimeoutError`:

```
async def main():
    try:
        async with asyncio.timeout(10):
            await long_running_task()
    except TimeoutError:
        print("The long operation timed out, but we")

    print("This statement will run regardless.")
```

The context manager produced by `asyncio.timeout()` can be rescheduled to a different deadline and inspected.

`class asyncio.Timeout(when)`

An **asynchronous context manager** for cancelling overdue coroutines.

`when` should be an absolute time at which the context should time out, as measured by the event loop's clock:

- If `when` is `None`, the timeout will never trigger.
- If `when < loop.time()`, the timeout will trigger on the next iteration of the event loop.

`when() → float | None`

Return the current deadline, or `None` if the current deadline is not set.

`reschedule(when: float | None)`

Reschedule the timeout.

`expired() → bool`

Return whether the context manager has exceeded its deadline (expired).

Example:

```
async def main():
    try:
        # We do not know the timeout when starting,
        async with asyncio.timeout(None) as cm:
            # We know the timeout now, so we resche
            new_deadline = get_running_loop().time(
                cm.reschedule(new_deadline)

            await long_running_task()
    except TimeoutError:
        pass
```

```
if cm.expired():
    print("Looks like we haven't finished on ti
```

Timeout context managers can be safely nested.

*New in version 3.11.*

*coroutine* `asyncio.timeout_at(when)`

Similar to `asyncio.timeout()`, except *when* is the absolute time to stop waiting, or `None`.

Example:

```
async def main():
    loop = get_running_loop()
    deadline = loop.time() + 20
    try:
        async with asyncio.timeout_at(deadline):
            await long_running_task()
    except TimeoutError:
        print("The long operation timed out, but we

    print("This statement will run regardless.")
```

*New in version 3.11.*

*coroutine* `asyncio.wait_for(aw, timeout)`

Wait for the *aw* [awaitable](#) to complete with a timeout.

If *aw* is a coroutine it is automatically scheduled as a Task.

*timeout* can either be `None` or a float or int number of seconds to wait for. If *timeout* is `None`, block until the future completes.

If a timeout occurs, it cancels the task and raises [TimeoutError](#).

To avoid the task [cancellation](#), wrap it in `shield()`.

The function will wait until the future is actually cancelled, so the total wait time may exceed the *timeout*. If an exception happens during cancellation, it is propagated.

If the wait is cancelled, the future *aw* is also cancelled.

*Changed in version 3.10:* Removed the *loop* parameter.

Example:

```
async def eternity():
    # Sleep for one hour
    await asyncio.sleep(3600)
    print('yay!')

async def main():
    # Wait for at most 1 second
    try:
        await asyncio.wait_for(eternity(), timeout=1)
    except TimeoutError:
        print('timeout!')

asyncio.run(main())

# Expected output:
#
#     timeout!
```

*Changed in version 3.7:* When *aw* is cancelled due to a timeout, `wait_for` waits for *aw* to be cancelled. Previously, it raised **TimeoutError** immediately.

*Changed in version 3.10:* Removed the *loop* parameter.

## Waiting Primitives

*coroutine* `asyncio.wait(aws, *, timeout=None, return_when=ALL_COMPLETED)`

Run **Future** and **Task** instances in the *aws* iterable

concurrently and block until the condition specified by *return\_when*.

The *aws* iterable must not be empty and generators yielding tasks are not accepted.

Returns two sets of Tasks/Futures: (*done*, *pending*).

Usage:

```
done, pending = await asyncio.wait(aws)
```

*timeout* (a float or int), if specified, can be used to control the maximum number of seconds to wait before returning.

Note that this function does not raise **TimeoutError**. Futures or Tasks that aren't done when the timeout occurs are simply returned in the second set.

*return\_when* indicates when this function should return. It must be one of the following constants:

#### **Description**

---

**FIRST\_COMPLETED** Return when any future finishes or is cancelled.

---

**FIRST\_EXCEPTION** Return when any future finishes by raising an exception. If no future raises an exception then it is equivalent to **ALL\_COMPLETED**.

---

**ALL\_COMPLETED** Return when all futures finish or are cancelled.

---

Unlike **wait\_for()**, **wait()** does not cancel the futures when a timeout occurs.

*Changed in version 3.10:* Removed the *loop* parameter.

*Changed in version 3.11:* Passing coroutine objects to **wait()** directly is forbidden.

`asyncio.as_completed(aws, *, timeout=None)`

Run **awaitable objects** in the *aws* iterable concurrently.

Generators yielding tasks are not accepted as *aws* iterable. Return an iterator of coroutines. Each coroutine returned can be awaited to get the earliest next result from the iterable of the remaining awaitables.

Raises **TimeoutError** if the timeout occurs before all Futures are done.

Example:

```
for coro in as_completed(aws):
    earliest_result = await coro
    # ...
```

*Changed in version 3.10:* Removed the *loop* parameter.

*Deprecated since version 3.10:* Deprecation warning is emitted if not all awaitable objects in the *aws* iterable are Future-like objects and there is no running event loop.

## Running in Threads

*coroutine* `asyncio.to_thread(func, /, *args, **kwargs)`

Asynchronously run function *func* in a separate thread.

Any *\*args* and *\*\*kwargs* supplied for this function are directly passed to *func*. Also, the current **contextvars.Context** is propagated, allowing context variables from the event loop thread to be accessed in the separate thread.

Return a coroutine that can be awaited to get the eventual result of *func*.

This coroutine function is primarily intended to be used for executing IO-bound functions/methods that would otherwise block the event loop if they were run in the main thread. For example:

```
def blocking_io():
    print(f"start blocking_io at {time.strftime('%X
```

```

    # Note that time.sleep() can be replaced with a
    # IO-bound operation, such as file operations.
    time.sleep(1)
    print(f"blocking_io complete at {time.strftime(

async def main():
    print(f"started main at {time.strftime('%X')}")

    await asyncio.gather(
        asyncio.to_thread(blocking_io),
        asyncio.sleep(1))

    print(f"finished main at {time.strftime('%X')}")

asyncio.run(main())

# Expected output:
#
# started main at 19:50:53
# start blocking_io at 19:50:53
# blocking_io complete at 19:50:54
# finished main at 19:50:54

```

Directly calling `blocking_io()` in any coroutine would block the event loop for its duration, resulting in an additional 1 second of run time. Instead, by using `asyncio.to_thread()`, we can run it in a separate thread without blocking the event loop.

## Note

Due to the [GIL](#), `asyncio.to_thread()` can typically only be used to make IO-bound functions non-blocking. However, for extension modules that release the GIL or alternative Python implementations that don't have one, `asyncio.to_thread()` can also be used for CPU-bound functions.

*New in version 3.9.*

## Scheduling From Other Threads

`asyncio.run_coroutine_threadsafe(coro, loop)`

Submit a coroutine to the given event loop. Thread-safe.

Return a `concurrent.futures.Future` to wait for the result from another OS thread.

This function is meant to be called from a different OS thread than the one where the event loop is running. Example:

```
# Create a coroutine
coro = asyncio.sleep(1, result=3)

# Submit the coroutine to a given loop
future = asyncio.run_coroutine_threadsafe(coro, loop)

# Wait for the result with an optional timeout argument
assert future.result(timeout) == 3
```

If an exception is raised in the coroutine, the returned Future will be notified. It can also be used to cancel the task in the event loop:

```
try:
    result = future.result(timeout)
except TimeoutError:
    print('The coroutine took too long, cancelling')
    future.cancel()
except Exception as exc:
    print(f'The coroutine raised an exception: {exc}')
else:
    print(f'The coroutine returned: {result!r}')
```

See the [concurrency and multithreading](#) section of the documentation.

Unlike other `asyncio` functions this function requires the `loop` argument to be passed explicitly.

*New in version 3.5.1.*

## Introspection

`asyncio.current_task(loop=None)`

Return the currently running **Task** instance, or `None` if no task is running.

If `loop` is `None` `get_running_loop()` is used to get the current loop.

*New in version 3.7.*

`asyncio.all_tasks(loop=None)`

Return a set of not yet finished **Task** objects run by the loop.

If `loop` is `None`, `get_running_loop()` is used for getting current loop.

*New in version 3.7.*

`asyncio.iscoroutine(obj)`

Return `True` if `obj` is a coroutine object.

*New in version 3.4.*

## Task Object

`class asyncio.Task(coro, *, loop=None, name=None, context=None)`

A **Future-like** object that runs a Python **coroutine**. Not thread-safe.

Tasks are used to run coroutines in event loops. If a coroutine awaits on a Future, the Task suspends the execution of the coroutine and waits for the completion of the Future. When

the Future is *done*, the execution of the wrapped coroutine resumes.

Event loops use cooperative scheduling: an event loop runs one Task at a time. While a Task awaits for the completion of a Future, the event loop runs other Tasks, callbacks, or performs IO operations.

Use the high-level `asyncio.create_task()` function to create Tasks, or the low-level `loop.create_task()` or `ensure_future()` functions. Manual instantiation of Tasks is discouraged.

To cancel a running Task use the `cancel()` method. Calling it will cause the Task to throw a `CancelledError` exception into the wrapped coroutine. If a coroutine is awaiting on a Future object during cancellation, the Future object will be cancelled.

`cancelled()` can be used to check if the Task was cancelled. The method returns `True` if the wrapped coroutine did not suppress the `CancelledError` exception and was actually cancelled.

`asyncio.Task` inherits from `Future` all of its APIs except `Future.set_result()` and `Future.set_exception()`.

An optional keyword-only *context* argument allows specifying a custom `contextvars.Context` for the *coro* to run in. If no *context* is provided, the Task copies the current context and later runs its coroutine in the copied context.

*Changed in version 3.7:* Added support for the `contextvars` module.

*Changed in version 3.8:* Added the *name* parameter.

*Deprecated since version 3.10:* Deprecation warning is emitted if *loop* is not specified and there is no running event loop.

*Changed in version 3.11:* Added the *context* parameter.

`done()`

Return `True` if the Task is *done*.

A Task is *done* when the wrapped coroutine either returned a value, raised an exception, or the Task was cancelled.

`result()`

Return the result of the Task.

If the Task is *done*, the result of the wrapped coroutine is returned (or if the coroutine raised an exception, that exception is re-raised.)

If the Task has been *cancelled*, this method raises a **CancelledError** exception.

If the Task's result isn't yet available, this method raises a **InvalidStateError** exception.

`exception()`

Return the exception of the Task.

If the wrapped coroutine raised an exception that exception is returned. If the wrapped coroutine returned normally this method returns `None`.

If the Task has been *cancelled*, this method raises a **CancelledError** exception.

If the Task isn't *done* yet, this method raises an **InvalidStateError** exception.

`add_done_callback(callback, *, context=None)`

Add a callback to be run when the Task is *done*.

This method should only be used in low-level callback-based code.

See the documentation of `Future.add_done_callback()` for more details.

`remove_done_callback(callback)`

Remove *callback* from the callbacks list.

This method should only be used in low-level callback-based code.

See the documentation of `Future.remove_done_callback()` for more details.

`get_stack(*, limit=None)`

Return the list of stack frames for this Task.

If the wrapped coroutine is not done, this returns the stack where it is suspended. If the coroutine has completed successfully or was cancelled, this returns an empty list. If the coroutine was terminated by an exception, this returns the list of traceback frames.

The frames are always ordered from oldest to newest.

Only one stack frame is returned for a suspended coroutine.

The optional *limit* argument sets the maximum number of frames to return; by default all available frames are returned. The ordering of the returned list differs depending on whether a stack or a traceback is returned: the newest frames of a stack are returned, but the oldest frames of a traceback are returned. (This matches the behavior of the traceback module.)

`print_stack(*, limit=None, file=None)`

Print the stack or traceback for this Task.

This produces output similar to that of the traceback

module for the frames retrieved by `get_stack()`.

The *limit* argument is passed to `get_stack()` directly.

The *file* argument is an I/O stream to which the output is written; by default output is written to `sys.stdout`.

`get_coro()`

Return the coroutine object wrapped by the `Task`.

*New in version 3.8.*

`get_name()`

Return the name of the `Task`.

If no name has been explicitly assigned to the `Task`, the default asyncio `Task` implementation generates a default name during instantiation.

*New in version 3.8.*

`set_name(value)`

Set the name of the `Task`.

The *value* argument can be any object, which is then converted to a string.

In the default `Task` implementation, the name will be visible in the `repr()` output of a task object.

*New in version 3.8.*

`cancel(msg=None)`

Request the `Task` to be cancelled.

This arranges for a `CancelledError` exception to be thrown into the wrapped coroutine on the next cycle of the event loop.

The coroutine then has a chance to clean up or even deny the request by suppressing the exception with a `try ... except CancellationError ... finally` block. Therefore, unlike `Future.cancel()`, `Task.cancel()` does not guarantee that the Task will be cancelled, although suppressing cancellation completely is not common and is actively discouraged. Should the coroutine nevertheless decide to suppress the cancellation, it needs to call `Task.uncancel()` in addition to catching the exception.

*Changed in version 3.9:* Added the `msg` parameter.

*Changed in version 3.11:* The `msg` parameter is propagated from cancelled task to its awaiter.

The following example illustrates how coroutines can intercept the cancellation request:

```
async def cancel_me():
    print('cancel_me(): before sleep')

    try:
        # Wait for 1 hour
        await asyncio.sleep(3600)
    except asyncio.CancelledError:
        print('cancel_me(): cancel sleep')
        raise
    finally:
        print('cancel_me(): after sleep')

async def main():
    # Create a "cancel_me" Task
    task = asyncio.create_task(cancel_me())

    # Wait for 1 second
    await asyncio.sleep(1)

    task.cancel()
    try:
```

```

        await task
    except asyncio.CancelledError:
        print("main(): cancel_me is cancelled")

asyncio.run(main())

# Expected output:
#
#      cancel_me(): before sleep
#      cancel_me(): cancel sleep
#      cancel_me(): after sleep
#      main(): cancel_me is cancelled now

```

## cancelled()

Return `True` if the Task is *cancelled*.

The Task is *cancelled* when the cancellation was requested with `cancel()` and the wrapped coroutine propagated the `CancelledError` exception thrown into it.

## uncancel()

Decrement the count of cancellation requests to this Task.

Returns the remaining number of cancellation requests.

Note that once execution of a cancelled task completed, further calls to `uncancel()` are ineffective.

*New in version 3.11.*

This method is used by asyncio's internals and isn't expected to be used by end-user code. In particular, if a Task gets successfully uncanceled, this allows for elements of structured concurrency like `Task Groups` and `asyncio.timeout()` to continue running, isolating cancellation to the respective structured block. For example:

```

async def make_request_with_timeout():
    try:
        async with asyncio.timeout(1):
            # Structured block affected by the
            await make_request()
            await make_another_request()
    except TimeoutError:
        log("There was a timeout")
    # Outer code not affected by the timeout:
    await unrelated_code()

```

While the block with `make_request()` and `make_another_request()` might get cancelled due to the timeout, `unrelated_code()` should continue running even in case of the timeout. This is implemented with `uncancel()`. `TaskGroup` context managers use `uncancel()` in a similar fashion.

If end-user code is, for some reason, suppressing cancellation by catching `CancelledError`, it needs to call this method to remove the cancellation state.

## cancelling()

Return the number of pending cancellation requests to this Task, i.e., the number of calls to `cancel()` less the number of `uncancel()` calls.

Note that if this number is greater than zero but the Task is still executing, `cancelled()` will still return `False`. This is because this number can be lowered by calling `uncancel()`, which can lead to the task not being cancelled after all if the cancellation requests go down to zero.

This method is used by `asyncio`'s internals and isn't expected to be used by end-user code. See `uncancel()` for more details.

*New in version 3.11.*

# Streams

**Source code:** [Lib/asyncio/streams.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/streams.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/streams.py]

---

Streams are high-level async/await-ready primitives to work with network connections. Streams allow sending and receiving data without using callbacks or low-level protocols and transports.

Here is an example of a TCP echo client written using asyncio streams:

```
import asyncio

async def tcp_echo_client(message):
    reader, writer = await asyncio.open_connection(
        '127.0.0.1', 8888)

    print(f'Send: {message!r}')
    writer.write(message.encode())
    await writer.drain()

    data = await reader.read(100)
    print(f'Received: {data.decode()!r}')

    print('Close the connection')
    writer.close()
    await writer.wait_closed()

asyncio.run(tcp_echo_client('Hello World!'))
```

See also the [Examples](#) section below.

## Stream Functions

The following top-level asyncio functions can be used to create and work with streams:

```
coroutine asyncio.open_connection(host=None, port=None, *,  
limit=None, ssl=None, family=0, proto=0, flags=0, sock=None,  
local_addr=None, server_hostname=None,  
ssl_handshake_timeout=None, ssl_shutdown_timeout=None,  
happy_eyeballs_delay=None, interleave=None)
```

Establish a network connection and return a pair of  
(*reader, writer*) objects.

The returned *reader* and *writer* objects are instances of  
**StreamReader** and **StreamWriter** classes.

*limit* determines the buffer size limit used by the returned  
**StreamReader** instance. By default the *limit* is set to 64 KiB.

The rest of the arguments are passed directly to  
**loop.create\_connection()**.

### Note

The *sock* argument transfers ownership of the socket to the  
**StreamWriter** created. To close the socket, call its  
**close()** method.

*Changed in version 3.7:* Added the *ssl\_handshake\_timeout*  
parameter.

*New in version 3.8:* Added *happy\_eyeballs\_delay* and *interleave*  
parameters.

*Changed in version 3.10:* Removed the *loop* parameter.

*Changed in version 3.11:* Added the *ssl\_shutdown\_timeout*  
parameter.

```
coroutine asyncio.start_server(client_connected_cb, host=None,  
port=None, *, limit=None, family=socket.AF_UNSPEC,  
flags=socket.AI_PASSIVE, sock=None, backlog=100, ssl=None,
```

*reuse\_address = None, reuse\_port = None, ssl\_handshake\_timeout = None, ssl\_shutdown\_timeout = None, start\_serving = True)*

Start a socket server.

The *client\_connected\_cb* callback is called whenever a new client connection is established. It receives a (*reader*, *writer*) pair as two arguments, instances of the **StreamReader** and **StreamWriter** classes.

*client\_connected\_cb* can be a plain callable or a **coroutine function**; if it is a coroutine function, it will be automatically scheduled as a **Task**.

*limit* determines the buffer size limit used by the returned **StreamReader** instance. By default the *limit* is set to 64 KiB.

The rest of the arguments are passed directly to **loop.create\_server()**.

### Note

The *sock* argument transfers ownership of the socket to the server created. To close the socket, call the server's **close()** method.

*Changed in version 3.7:* Added the *ssl\_handshake\_timeout* and *start\_serving* parameters.

*Changed in version 3.10:* Removed the *loop* parameter.

*Changed in version 3.11:* Added the *ssl\_shutdown\_timeout* parameter.

## Unix Sockets

*coroutine* **asyncio.open\_unix\_connection**(*path = None*, \*, *limit = None*, *ssl = None*, *sock = None*, *server\_hostname = None*, *ssl\_handshake\_timeout = None*, *ssl\_shutdown\_timeout = None*)

Establish a Unix socket connection and return a pair of (reader, writer).

Similar to `open_connection()` but operates on Unix sockets.

See also the documentation of `loop.create_unix_connection()`.

### Note

The *sock* argument transfers ownership of the socket to the `StreamWriter` created. To close the socket, call its `close()` method.

**Availability:** Unix.

*Changed in version 3.7:* Added the *ssl\_handshake\_timeout* parameter. The *path* parameter can now be a [path-like object](#)

*Changed in version 3.10:* Removed the *loop* parameter.

*Changed in version 3.11:* Added the *ssl\_shutdown\_timeout* parameter.

```
coroutine asyncio.start_unix_server(client_connected_cb, path=None, *,
limit=None, sock=None, backlog=100, ssl=None,
ssl_handshake_timeout=None, ssl_shutdown_timeout=None,
start_serving=True)
```

Start a Unix socket server.

Similar to `start_server()` but works with Unix sockets.

See also the documentation of `loop.create_unix_server()`.

### Note

The *sock* argument transfers ownership of the socket to the server created. To close the socket, call the server's `close()` method.

**Availability:** Unix.

*Changed in version 3.7:* Added the `ssl_handshake_timeout` and `start_serving` parameters. The `path` parameter can now be a [path-like object](#).

*Changed in version 3.10:* Removed the `loop` parameter.

*Changed in version 3.11:* Added the `ssl_shutdown_timeout` parameter.

## StreamReader

*class* `asyncio.StreamReader`

Represents a reader object that provides APIs to read data from the IO stream. As an [asynchronous iterable](#), the object supports the `async for` statement.

It is not recommended to instantiate *StreamReader* objects directly; use `open_connection()` and `start_server()` instead.

*coroutine* `read(n=-1)`

Read up to *n* bytes from the stream.

If *n* is not provided or set to `-1`, read until EOF, then return all read [bytes](#). If EOF was received and the internal buffer is empty, return an empty `bytes` object.

If *n* is `0`, return an empty `bytes` object immediately.

If *n* is positive, return at most *n* available `bytes` as soon as at least 1 byte is available in the internal buffer. If EOF is received before any byte is read, return an empty `bytes` object.

*coroutine* `readline()`

Read one line, where “line” is a sequence of bytes ending with `\n`.

If EOF is received and `\n` was not found, the method returns partially read data.

If EOF is received and the internal buffer is empty, return an empty `bytes` object.

*coroutine* `readexactly(n)`

Read exactly *n* bytes.

Raise an `IncompleteReadError` if EOF is reached before *n* can be read. Use the `IncompleteReadError.partial` attribute to get the partially read data.

*coroutine* `readuntil(separator=b'\n')`

Read data from the stream until *separator* is found.

On success, the data and separator will be removed from the internal buffer (consumed). Returned data will include the separator at the end.

If the amount of data read exceeds the configured stream limit, a `LimitOverrunError` exception is raised, and the data is left in the internal buffer and can be read again.

If EOF is reached before the complete separator is found, an `IncompleteReadError` exception is raised, and the internal buffer is reset. The `IncompleteReadError.partial` attribute may contain a portion of the separator.

*New in version 3.5.2.*

`at_eof()`

Return `True` if the buffer is empty and `feed_eof()` was called.

## StreamWriter

`class asyncio.StreamWriter`

Represents a writer object that provides APIs to write data to the IO stream.

It is not recommended to instantiate *StreamWriter* objects directly; use `open_connection()` and `start_server()` instead.

`write(data)`

The method attempts to write the *data* to the underlying socket immediately. If that fails, the data is queued in an internal write buffer until it can be sent.

The method should be used along with the `drain()` method:

```
stream.write(data)
await stream.drain()
```

`writelines(data)`

The method writes a list (or any iterable) of bytes to the underlying socket immediately. If that fails, the data is queued in an internal write buffer until it can be sent.

The method should be used along with the `drain()` method:

```
stream.writelines(lines)
await stream.drain()
```

`close()`

The method closes the stream and the underlying

socket.

The method should be used, though not mandatory, along with the `wait_closed()` method:

```
stream.close()
await stream.wait_closed()
```

`can_write_eof()`

Return `True` if the underlying transport supports the `write_eof()` method, `False` otherwise.

`write_eof()`

Close the write end of the stream after the buffered write data is flushed.

`transport`

Return the underlying asyncio transport.

`get_extra_info(name, default=None)`

Access optional transport information; see `BaseTransport.get_extra_info()` for details.

*coroutine* `drain()`

Wait until it is appropriate to resume writing to the stream. Example:

```
writer.write(data)
await writer.drain()
```

This is a flow control method that interacts with the underlying IO write buffer. When the size of the buffer reaches the high watermark, `drain()` blocks until the size of the buffer is drained down to the low watermark and writing can be resumed. When there is nothing to wait for, the `drain()` returns immediately.

*coroutine* `start_tls(sslcontext, \*, server_hostname=None, ssl_handshake_timeout=None)`

Upgrade an existing stream-based connection to TLS.

Parameters:

- *sslcontext*: a configured instance of `SSLContext`.
- *server\_hostname*: sets or overrides the host name that the target server's certificate will be matched against.
- *ssl\_handshake\_timeout* is the time in seconds to wait for the TLS handshake to complete before aborting the connection. 60.0 seconds if `None` (default).

*New in version 3.11.*

`is_closing()`

Return `True` if the stream is closed or in the process of being closed.

*New in version 3.7.*

*coroutine* `wait_closed()`

Wait until the stream is closed.

Should be called after `close()` to wait until the underlying connection is closed, ensuring that all data has been flushed before e.g. exiting the program.

*New in version 3.7.*

## Examples

### TCP echo client using streams

TCP echo client using the `asyncio.open_connection()` function:

```
import asyncio

async def tcp_echo_client(message):
    reader, writer = await asyncio.open_connection(
        '127.0.0.1', 8888)

    print(f'Send: {message!r}')
    writer.write(message.encode())
    await writer.drain()

    data = await reader.read(100)
    print(f'Received: {data.decode()!r}')

    print('Close the connection')
    writer.close()
    await writer.wait_closed()

asyncio.run(tcp_echo_client('Hello World!'))
```

## See also

The [TCP echo client protocol](#) example uses the low-level [loop.create\\_connection\(\)](#) method.

## TCP echo server using streams

TCP echo server using the [asyncio.start\\_server\(\)](#) function:

```
import asyncio

async def handle_echo(reader, writer):
    data = await reader.read(100)
    message = data.decode()
    addr = writer.get_extra_info('peername')

    print(f"Received {message!r} from {addr!r}")

    print(f"Send: {message!r}")
```

```

writer.write(data)
await writer.drain()

print("Close the connection")
writer.close()
await writer.wait_closed()

async def main():
    server = await asyncio.start_server(
        handle_echo, '127.0.0.1', 8888)

    addrs = ', '.join(str(sock.getsockname()) for sock in server.sockets)
    print(f'Serving on {addrs}')

    async with server:
        await server.serve_forever()

asyncio.run(main())

```

## See also

The [TCP echo server protocol](#) example uses the [`loop.create\_server\(\)`](#) method.

## Get HTTP headers

Simple example querying HTTP headers of the URL passed on the command line:

```

import asyncio
import urllib.parse
import sys

async def print_http_headers(url):
    url = urllib.parse.urlsplit(url)
    if url.scheme == 'https':
        reader, writer = await asyncio.open_connection(
            url.hostname, 443, ssl=True)

```

```

else:
    reader, writer = await asyncio.open_connection(
        url.hostname, 80)

    query = (
        f"HEAD {url.path or '/'} HTTP/1.0\r\n"
        f"Host: {url.hostname}\r\n"
        f"\r\n"
    )

    writer.write(query.encode('latin-1'))
    while True:
        line = await reader.readline()
        if not line:
            break

        line = line.decode('latin1').rstrip()
        if line:
            print(f'HTTP header> {line}')

    # Ignore the body, close the socket
    writer.close()
    await writer.wait_closed()

```

```

url = sys.argv[1]
asyncio.run(print_http_headers(url))

```

### Usage:

```
python example.py http://example.com/path/page.html
```

or with HTTPS:

```
python example.py https://example.com/path/page.html
```

## Register an open socket to wait for data using streams

Coroutine waiting until a socket receives data using the [open\\_connection\(\)](#) function:

```
import asyncio
import socket

async def wait_for_data():
    # Get a reference to the current event loop because
    # we want to access low-level APIs.
    loop = asyncio.get_running_loop()

    # Create a pair of connected sockets.
    rsock, wsock = socket.socketpair()

    # Register the open socket to wait for data.
    reader, writer = await asyncio.open_connection(sock=

    # Simulate the reception of data from the network
    loop.call_soon(wsock.send, 'abc'.encode())

    # Wait for data
    data = await reader.read(100)

    # Got data, we are done: close the socket
    print("Received:", data.decode())
    writer.close()
    await writer.wait_closed()

    # Close the second socket
    wsock.close()

asyncio.run(wait_for_data())
```

## See also

The [register an open socket to wait for data using a protocol](#) example uses a low-level protocol and the [loop.create\\_connection\(\)](#) method.

The [watch a file descriptor for read events](#) example uses the low-level [loop.add\\_reader\(\)](#) method to watch a file descriptor.

# Synchronization Primitives

**Source code:** [Lib/asyncio/locks.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/locks.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/locks.py]

---

asyncio synchronization primitives are designed to be similar to those of the `threading` module with two important caveats:

- asyncio primitives are not thread-safe, therefore they should not be used for OS thread synchronization (use `threading` for that);
- methods of these synchronization primitives do not accept the *timeout* argument; use the `asyncio.wait_for()` function to perform operations with timeouts.

asyncio has the following basic synchronization primitives:

- `Lock`
  - `Event`
  - `Condition`
  - `Semaphore`
  - `BoundedSemaphore`
  - `Barrier`
- 

## Lock

`class asyncio.Lock`

Implements a mutex lock for asyncio tasks. Not thread-safe.

An asyncio lock can be used to guarantee exclusive access to a shared resource.

The preferred way to use a Lock is an `async with` statement:

```
lock = asyncio.Lock()

# ... later
async with lock:
    # access shared state
```

which is equivalent to:

```
lock = asyncio.Lock()

# ... later
await lock.acquire()
try:
    # access shared state
finally:
    lock.release()
```

*Changed in version 3.10:* Removed the *loop* parameter.

*coroutine* `acquire()`

Acquire the lock.

This method waits until the lock is *unlocked*, sets it to *locked* and returns `True`.

When more than one coroutine is blocked in `acquire()` waiting for the lock to be unlocked, only one coroutine eventually proceeds.

Acquiring a lock is *fair*: the coroutine that proceeds will be the first coroutine that started waiting on the lock.

`release()`

Release the lock.

When the lock is *locked*, reset it to *unlocked* and return.

If the lock is *unlocked*, a `RuntimeError` is raised.

`locked()`

Return `True` if the lock is *locked*.

## Event

`class asyncio.Event`

An event object. Not thread-safe.

An asyncio event can be used to notify multiple asyncio tasks that some event has happened.

An Event object manages an internal flag that can be set to *true* with the `set()` method and reset to *false* with the `clear()` method. The `wait()` method blocks until the flag is set to *true*. The flag is set to *false* initially.

*Changed in version 3.10:* Removed the `loop` parameter.

Example:

```
async def waiter(event):
    print('waiting for it ...')
    await event.wait()
    print('... got it!')
```

```
async def main():
    # Create an Event object.
    event = asyncio.Event()

    # Spawn a Task to wait until 'event' is set.
    waiter_task = asyncio.create_task(waiter(event))

    # Sleep for 1 second and set the event.
    await asyncio.sleep(1)
    event.set()

    # Wait until the waiter task is finished.
    await waiter_task

asyncio.run(main())
```

*coroutine* `wait()`

Wait until the event is set.

If the event is set, return `True` immediately. Otherwise block until another task calls `set()`.

`set()`

Set the event.

All tasks waiting for event to be set will be immediately awakened.

`clear()`

Clear (unset) the event.

Tasks awaiting on `wait()` will now block until the `set()` method is called again.

`is_set()`

Return `True` if the event is set.

## Condition

*class* `asyncio.Condition(lock=None)`

A Condition object. Not thread-safe.

An asyncio condition primitive can be used by a task to wait for some event to happen and then get exclusive access to a shared resource.

In essence, a Condition object combines the functionality of an `Event` and a `Lock`. It is possible to have multiple Condition objects share one Lock, which allows coordinating exclusive access to a shared resource between different tasks interested in particular states of that shared resource.

The optional *lock* argument must be a `Lock` object or `None`. In the latter case a new Lock object is created automatically.

*Changed in version 3.10:* Removed the *loop* parameter.

The preferred way to use a Condition is an **async with** statement:

```
cond = asyncio.Condition()

# ... later
async with cond:
    await cond.wait()
```

which is equivalent to:

```
cond = asyncio.Condition()

# ... later
await cond.acquire()
try:
    await cond.wait()
finally:
    cond.release()
```

*coroutine* **acquire()**

Acquire the underlying lock.

This method waits until the underlying lock is *unlocked*, sets it to *locked* and returns `True`.

**notify(*n*=1)**

Wake up at most *n* tasks (1 by default) waiting on this condition. The method is no-op if no tasks are waiting.

The lock must be acquired before this method is called and released shortly after. If called with an *unlocked* lock a **RuntimeError** error is raised.

**locked()**

Return `True` if the underlying lock is acquired.

`notify_all()`

Wake up all tasks waiting on this condition.

This method acts like `notify()`, but wakes up all waiting tasks.

The lock must be acquired before this method is called and released shortly after. If called with an *unlocked* lock a `RuntimeError` error is raised.

`release()`

Release the underlying lock.

When invoked on an unlocked lock, a `RuntimeError` is raised.

*coroutine* `wait()`

Wait until notified.

If the calling task has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method releases the underlying lock, and then blocks until it is awakened by a `notify()` or `notify_all()` call. Once awakened, the Condition re-acquires its lock and this method returns `True`.

*coroutine* `wait_for(predicate)`

Wait until a predicate becomes *true*.

The predicate must be a callable which result will be interpreted as a boolean value. The final value is the return value.

## Semaphore

`class asyncio.Semaphore(value = 1)`

A Semaphore object. Not thread-safe.

A semaphore manages an internal counter which is decremented by each `acquire()` call and incremented by each `release()` call. The counter can never go below zero; when `acquire()` finds that it is zero, it blocks, waiting until some task calls `release()`.

The optional *value* argument gives the initial value for the internal counter (1 by default). If the given value is less than 0 a `ValueError` is raised.

*Changed in version 3.10:* Removed the *loop* parameter.

The preferred way to use a Semaphore is an `async with` statement:

```
sem = asyncio.Semaphore(10)

# ... later
async with sem:
    # work with shared resource
```

which is equivalent to:

```
sem = asyncio.Semaphore(10)

# ... later
await sem.acquire()
try:
    # work with shared resource
finally:
    sem.release()
```

*coroutine* `acquire()`

Acquire a semaphore.

If the internal counter is greater than zero, decrement it by one and return `True` immediately. If it is zero, wait until a `release()` is called and return `True`.

`locked()`

Returns `True` if semaphore can not be acquired immediately.

`release()`

Release a semaphore, incrementing the internal counter by one. Can wake up a task waiting to acquire the semaphore.

Unlike `BoundedSemaphore`, `Semaphore` allows making more `release()` calls than `acquire()` calls.

## BoundedSemaphore

`class asyncio.BoundedSemaphore(value = 1)`

A bounded semaphore object. Not thread-safe.

Bounded Semaphore is a version of `Semaphore` that raises a `ValueError` in `release()` if it increases the internal counter above the initial `value`.

*Changed in version 3.10:* Removed the `loop` parameter.

## Barrier

`class asyncio.Barrier(parties)`

A barrier object. Not thread-safe.

A barrier is a simple synchronization primitive that allows to block until `parties` number of tasks are waiting on it. Tasks can wait on the `wait()` method and would be blocked until the specified number of tasks end up waiting on `wait()`. At that point all of the waiting tasks would unblock simultaneously.

`async with` can be used as an alternative to awaiting on `wait()`.

The barrier can be reused any number of times.

Example:

```
async def example_barrier():
    # barrier with 3 parties
    b = asyncio.Barrier(3)

    # create 2 new waiting tasks
    asyncio.create_task(b.wait())
    asyncio.create_task(b.wait())

    await asyncio.sleep(0)
    print(b)

    # The third .wait() call passes the barrier
    await b.wait()
    print(b)
    print("barrier passed")

    await asyncio.sleep(0)
    print(b)

asyncio.run(example_barrier())
```

Result of this example is:

```
<asyncio.locks.Barrier object at 0x... [filling, wa
<asyncio.locks.Barrier object at 0x... [draining, w
barrier passed
<asyncio.locks.Barrier object at 0x... [filling, wa
```

*New in version 3.11.*

*coroutine* wait()

Pass the barrier. When all the tasks party to the barrier have called this function, they are all unblocked simultaneously.

When a waiting or blocked task in the barrier is

cancelled, this task exits the barrier which stays in the same state. If the state of the barrier is “filling”, the number of waiting task decreases by 1.

The return value is an integer in the range of 0 to `parties-1`, different for each task. This can be used to select a task to do some special housekeeping, e.g.:

```
...
async with barrier as position:
    if position == 0:
        # Only one task prints this
        print('End of *draining phase*')
```

This method may raise a **BrokenBarrierError** exception if the barrier is broken or reset while a task is waiting. It could raise a **CancelledError** if a task is cancelled.

### *coroutine* `reset()`

Return the barrier to the default, empty state. Any tasks waiting on it will receive the **BrokenBarrierError** exception.

If a barrier is broken it may be better to just leave it and create a new one.

### *coroutine* `abort()`

Put the barrier into a broken state. This causes any active or future calls to `wait()` to fail with the **BrokenBarrierError**. Use this for example if one of the tasks needs to abort, to avoid infinite waiting tasks.

### `parties`

The number of tasks required to pass the barrier.

### `n_waiting`

The number of tasks currently waiting in the barrier while filling.

broken

A boolean that is `True` if the barrier is in the broken state.

*exception* `asyncio.BrokenBarrierError`

This exception, a subclass of `RuntimeError`, is raised when the `Barrier` object is reset or broken.

---

*Changed in version 3.9:* Acquiring a lock using `await lock` or `yield from lock` and/or `with` statement (with `await lock`, `with (yield from lock)`) was removed. Use `async with lock` instead.

# Subprocesses

**Source code:** [Lib/asyncio/subprocess.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/subprocess.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/subprocess.py], [Lib/asyncio/base\\_subprocess.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/base_subprocess.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/base\_subprocess.py]

---

This section describes high-level `async/await` `asyncio` APIs to create and manage subprocesses.

Here's an example of how `asyncio` can run a shell command and obtain its result:

```
import asyncio

async def run(cmd):
    proc = await asyncio.create_subprocess_shell(
        cmd,
        stdout=asyncio.subprocess.PIPE,
        stderr=asyncio.subprocess.PIPE)

    stdout, stderr = await proc.communicate()

    print(f'[{cmd!r}] exited with {proc.returncode}')]
    if stdout:
        print(f'[stdout]\n{stdout.decode()}')]
    if stderr:
        print(f'[stderr]\n{stderr.decode()}')]

asyncio.run(run('ls /zzz'))

will print:

['ls /zzz' exited with 1]
[stderr]
```

```
ls: /zzz: No such file or directory
```

Because all `asyncio` subprocess functions are asynchronous and `asyncio` provides many tools to work with such functions, it is easy to execute and monitor multiple subprocesses in parallel. It is indeed trivial to modify the above example to run several commands simultaneously:

```
async def main():
    await asyncio.gather(
        run('ls /zzz'),
        run('sleep 1; echo "hello"'))
```

```
asyncio.run(main())
```

See also the [Examples](#) subsection.

## Creating Subprocesses

*coroutine* `asyncio.create_subprocess_exec(program, *args, stdin=None, stdout=None, stderr=None, limit=None, **kwargs)`

Create a subprocess.

The *limit* argument sets the buffer limit for [StreamReader](#) wrappers for `Process.stdout` and `Process.stderr` (if [subprocess.PIPE](#) is passed to *stdout* and *stderr* arguments).

Return a [Process](#) instance.

See the documentation of [loop.subprocess\\_exec\(\)](#) for other parameters.

*Changed in version 3.10:* Removed the *loop* parameter.

*coroutine* `asyncio.create_subprocess_shell(cmd, stdin=None, stdout=None, stderr=None, limit=None, **kwargs)`

Run the *cmd* shell command.

The *limit* argument sets the buffer limit for [StreamReader](#)

wrappers for `Process.stdout` and `Process.stderr` (if `subprocess.PIPE` is passed to `stdout` and `stderr` arguments).

Return a `Process` instance.

See the documentation of `loop.subprocess_shell()` for other parameters.

### Important

It is the application's responsibility to ensure that all whitespace and special characters are quoted appropriately to avoid [shell injection](https://en.wikipedia.org/wiki/Shell_injection#Shell_injection) [https://en.wikipedia.org/wiki/Shell\_injection#Shell\_injection] vulnerabilities. The `shlex.quote()` function can be used to properly escape whitespace and special shell characters in strings that are going to be used to construct shell commands.

*Changed in version 3.10:* Removed the `loop` parameter.

### Note

Subprocesses are available for Windows if a `ProactorEventLoop` is used. See [Subprocess Support on Windows](#) for details.

### See also

`asyncio` also has the following *low-level* APIs to work with subprocesses: `loop.subprocess_exec()`, `loop.subprocess_shell()`, `loop.connect_read_pipe()`, `loop.connect_write_pipe()`, as well as the [Subprocess Transports](#) and [Subprocess Protocols](#).

## Constants

`asyncio.subprocess.PIPE`

Can be passed to the *stdin*, *stdout* or *stderr* parameters.

If *PIPE* is passed to *stdin* argument, the `Process.stdin` attribute will point to a `StreamWriter` instance.

If *PIPE* is passed to *stdout* or *stderr* arguments, the `Process.stdout` and `Process.stderr` attributes will point to `StreamReader` instances.

`asyncio.subprocess.STDOUT`

Special value that can be used as the *stderr* argument and indicates that standard error should be redirected into standard output.

`asyncio.subprocess.DEVNULL`

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to process creation functions. It indicates that the special file `os.devnull` will be used for the corresponding subprocess stream.

## Interacting with Subprocesses

Both `create_subprocess_exec()` and `create_subprocess_shell()` functions return instances of the *Process* class. *Process* is a high-level wrapper that allows communicating with subprocesses and watching for their completion.

`class asyncio.subprocess.Process`

An object that wraps OS processes created by the `create_subprocess_exec()` and `create_subprocess_shell()` functions.

This class is designed to have a similar API to the `subprocess.Popen` class, but there are some notable differences:

- unlike *Popen*, *Process* instances do not have an equivalent to the `poll()` method;

- the `communicate()` and `wait()` methods don't have a *timeout* parameter: use the `wait_for()` function;
- the `Process.wait()` method is asynchronous, whereas `subprocess.Popen.wait()` method is implemented as a blocking busy loop;
- the *universal\_newlines* parameter is not supported.

This class is [not thread safe](#).

See also the [Subprocess and Threads](#) section.

*coroutine* `wait()`

Wait for the child process to terminate.

Set and return the `returncode` attribute.

### Note

This method can deadlock when using `stdout=PIPE` or `stderr=PIPE` and the child process generates so much output that it blocks waiting for the OS pipe buffer to accept more data. Use the `communicate()` method when using pipes to avoid this condition.

*coroutine* `communicate(input=None)`

Interact with process:

1. send data to *stdin* (if *input* is not `None`);
2. read data from *stdout* and *stderr*, until EOF is reached;
3. wait for process to terminate.

The optional *input* argument is the data (`bytes` object) that will be sent to the child process.

Return a tuple `(stdout_data, stderr_data)`.

If either `BrokenPipeError` or `ConnectionResetError` exception is raised when writing *input* into *stdin*, the exception is ignored. This condition occurs when the process exits before all data are written into *stdin*.

If it is desired to send data to the process' *stdin*, the process needs to be created with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, the process has to be created with `stdout=PIPE` and/or `stderr=PIPE` arguments.

Note, that the data read is buffered in memory, so do not use this method if the data size is large or unlimited.

`send_signal(signal)`

Sends the signal *signal* to the child process.

### Note

On Windows, **SIGTERM** is an alias for `terminate()`. `CTRL_C_EVENT` and `CTRL_BREAK_EVENT` can be sent to processes started with a *creationflags* parameter which includes `CREATE_NEW_PROCESS_GROUP`.

`terminate()`

Stop the child process.

On POSIX systems this method sends `signal.SIGTERM` to the child process.

On Windows the Win32 API function **TerminateProcess()** is called to stop the child process.

`kill()`

Kill the child process.

On POSIX systems this method sends **SIGKILL** to the child process.

On Windows this method is an alias for **`terminate()`**.

**stdin**

Standard input stream (**`StreamWriter`**) or `None` if the process was created with `stdin=None`.

**stdout**

Standard output stream (**`StreamReader`**) or `None` if the process was created with `stdout=None`.

**stderr**

Standard error stream (**`StreamReader`**) or `None` if the process was created with `stderr=None`.

### Warning

Use the **`communicate()`** method rather than **`process.stdin.write()`**, **`await process.stdout.read()`** or **`await process.stderr.read()`**. This avoids deadlocks due to streams pausing reading or writing and blocking the child process.

**pid**

Process identification number (PID).

Note that for processes created by the **`create_subprocess_shell()`** function, this attribute is the PID of the spawned shell.

**returncode**

Return code of the process when it exits.

A `None` value indicates that the process has not terminated yet.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

## Subprocess and Threads

Standard `asyncio` event loop supports running subprocesses from different threads by default.

On Windows subprocesses are provided by `ProactorEventLoop` only (default), `SelectorEventLoop` has no subprocess support.

On UNIX *child watchers* are used for subprocess finish waiting, see [Process Watchers](#) for more info.

*Changed in version 3.8:* UNIX switched to use `ThreadedChildWatcher` for spawning subprocesses from different threads without any limitation.

Spawning a subprocess with *inactive* current child watcher raises `RuntimeError`.

Note that alternative event loop implementations might have own limitations; please refer to their documentation.

### See also

The [Concurrency and multithreading in asyncio](#) section.

## Examples

An example using the `Process` class to control a subprocess and the `StreamReader` class to read from its standard output.

The subprocess is created by the `create_subprocess_exec()` function:

```
import asyncio
```

```
import sys

async def get_date():
    code = 'import datetime; print(datetime.datetime.now())'

    # Create the subprocess; redirect the standard output
    # into a pipe.
    proc = await asyncio.create_subprocess_exec(
        sys.executable, '-c', code,
        stdout=asyncio.subprocess.PIPE)

    # Read one line of output.
    data = await proc.stdout.readline()
    line = data.decode('ascii').rstrip()

    # Wait for the subprocess exit.
    await proc.wait()
    return line

date = asyncio.run(get_date())
print(f"Current date: {date}")
```

See also the [same example](#) written using low-level APIs.

# Queues

**Source code:** [Lib/asyncio/queues.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/queues.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/queues.py]

---

asyncio queues are designed to be similar to classes of the [queue](#) module. Although asyncio queues are not thread-safe, they are designed to be used specifically in `async/await` code.

Note that methods of asyncio queues don't have a *timeout* parameter; use [asyncio.wait\\_for\(\)](#) function to do queue operations with a timeout.

See also the [Examples](#) section below.

## Queue

`class asyncio.Queue(maxsize=0)`

A first in, first out (FIFO) queue.

If *maxsize* is less than or equal to zero, the queue size is infinite. If it is an integer greater than 0, then `await put()` blocks when the queue reaches *maxsize* until an item is removed by `get()`.

Unlike the standard library threading [queue](#), the size of the queue is always known and can be returned by calling the `qsize()` method.

*Changed in version 3.10:* Removed the *loop* parameter.

This class is [not thread safe](#).

**maxsize**

Number of items allowed in the queue.

`empty()`

Return `True` if the queue is empty, `False` otherwise.

`full()`

Return `True` if there are `maxsize` items in the queue.

If the queue was initialized with `maxsize=0` (the default), then `full()` never returns `True`.

*coroutine* `get()`

Remove and return an item from the queue. If queue is empty, wait until an item is available.

`get_nowait()`

Return an item if one is immediately available, else raise `QueueEmpty`.

*coroutine* `join()`

Block until all items in the queue have been received and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer coroutine calls `task_done()` to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, `join()` unblocks.

*coroutine* `put(item)`

Put an item into the queue. If the queue is full, wait until a free slot is available before adding the item.

`put_nowait(item)`

Put an item into the queue without blocking.

If no free slot is immediately available, raise `QueueFull`.

`qsize()`

Return the number of items in the queue.

`task_done()`

Indicate that a formerly enqueued task is complete.

Used by queue consumers. For each `get()` used to fetch a task, a subsequent call to `task_done()` tells the queue that the processing on the task is complete.

If a `join()` is currently blocking, it will resume when all items have been processed (meaning that a `task_done()` call was received for every item that had been `put()` into the queue).

Raises `ValueError` if called more times than there were items placed in the queue.

## Priority Queue

*class* `asyncio.PriorityQueue`

A variant of `Queue`; retrieves entries in priority order (lowest first).

Entries are typically tuples of the form  
(`priority_number`, `data`).

## LIFO Queue

*class* `asyncio.LifoQueue`

A variant of `Queue` that retrieves most recently added entries first (last in, first out).

## Exceptions

*exception* `asyncio.QueueEmpty`

This exception is raised when the `get_nowait()` method is

called on an empty queue.

*exception* `asyncio.QueueFull`

Exception raised when the `put_nowait()` method is called on a queue that has reached its *maxsize*.

## Examples

Queues can be used to distribute workload between several concurrent tasks:

```
import asyncio
import random
import time
```

```
async def worker(name, queue):
    while True:
        # Get a "work item" out of the queue.
        sleep_for = await queue.get()

        # Sleep for the "sleep_for" seconds.
        await asyncio.sleep(sleep_for)

        # Notify the queue that the "work item" has been
        queue.task_done()

    print(f'{name} has slept for {sleep_for:.2f} sec
```

```
async def main():
    # Create a queue that we will use to store our "work
    queue = asyncio.Queue()

    # Generate random timings and put them into the queue
    total_sleep_time = 0
    for _ in range(20):
        sleep_for = random.uniform(0.05, 1.0)
```

```

        total_sleep_time += sleep_for
        queue.put_nowait(sleep_for)

# Create three worker tasks to process the queue contents
tasks = []
for i in range(3):
    task = asyncio.create_task(worker(f'worker-{i}', sleep_for))
    tasks.append(task)

# Wait until the queue is fully processed.
started_at = time.monotonic()
await queue.join()
total_slept_for = time.monotonic() - started_at

# Cancel our worker tasks.
for task in tasks:
    task.cancel()

# Wait until all worker tasks are cancelled.
await asyncio.gather(*tasks, return_exceptions=True)

print('====')
print(f'3 workers slept in parallel for {total_slept_for} seconds')
print(f'total expected sleep time: {total_sleep_time} seconds')

asyncio.run(main())

```

# Exceptions

**Source code:** [Lib/asyncio/exceptions.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/exceptions.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/exceptions.py]

---

*exception* `asyncio.TimeoutError`

A deprecated alias of `TimeoutError`, raised when the operation has exceeded the given deadline.

*Changed in version 3.11:* This class was made an alias of `TimeoutError`.

*exception* `asyncio.CancelledError`

The operation has been cancelled.

This exception can be caught to perform custom operations when `asyncio` Tasks are cancelled. In almost all situations the exception must be re-raised.

*Changed in version 3.8:* `CancelledError` is now a subclass of `BaseException`.

*exception* `asyncio.InvalidStateError`

Invalid internal state of `Task` or `Future`.

Can be raised in situations like setting a result value for a `Future` object that already has a result value set.

*exception* `asyncio.SendfileNotAvailableError`

The “sendfile” syscall is not available for the given socket or file type.

A subclass of `RuntimeError`.

*exception* `asyncio.IncompleteReadError`

The requested read operation did not complete fully.

Raised by the [asyncio stream APIs](#).

This exception is a subclass of [EOFError](#).

expected

The total number ([int](#)) of expected bytes.

partial

A string of [bytes](#) read before the end of stream was reached.

*exception* `asyncio.LimitOverrunError`

Reached the buffer size limit while looking for a separator.

Raised by the [asyncio stream APIs](#).

consumed

The total number of to be consumed bytes.

# Event Loop

**Source code:** [Lib/asyncio/events.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/events.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/events.py], [Lib/asyncio/base\\_events.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/base_events.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/base\_events.py]

---

## Preface

The event loop is the core of every asyncio application. Event loops run asynchronous tasks and callbacks, perform network IO operations, and run subprocesses.

Application developers should typically use the high-level asyncio functions, such as `asyncio.run()`, and should rarely need to reference the loop object or call its methods. This section is intended mostly for authors of lower-level code, libraries, and frameworks, who need finer control over the event loop behavior.

## Obtaining the Event Loop

The following low-level functions can be used to get, set, or create an event loop:

`asyncio.get_running_loop()`

Return the running event loop in the current OS thread.

Raise a `RuntimeError` if there is no running event loop.

This function can only be called from a coroutine or a callback.

*New in version 3.7.*

`asyncio.get_event_loop()`

Get the current event loop.

When called from a coroutine or a callback (e.g. scheduled with `call_soon` or similar API), this function will always return the running event loop.

If there is no running event loop set, the function will return the result of the

`get_event_loop_policy().get_event_loop()` call.

Because this function has rather complex behavior (especially when custom event loop policies are in use), using the `get_running_loop()` function is preferred to `get_event_loop()` in coroutines and callbacks.

As noted above, consider using the higher-level `asyncio.run()` function, instead of using these lower level functions to manually create and close an event loop.

### Note

In Python versions 3.10.0–3.10.8 and 3.11.0 this function (and other functions which use it implicitly) emitted a `DeprecationWarning` if there was no running event loop, even if the current loop was set on the policy. In Python versions 3.10.9, 3.11.1 and 3.12 they emit a `DeprecationWarning` if there is no running event loop and no current loop is set. In some future Python release this will become an error.

`asyncio.set_event_loop(loop)`

Set *loop* as the current event loop for the current OS thread.

`asyncio.new_event_loop()`

Create and return a new event loop object.

Note that the behaviour of `get_event_loop()`,

`set_event_loop()`, and `new_event_loop()` functions can be altered by setting a custom event loop policy.

## Contents

This documentation page contains the following sections:

- The [Event Loop Methods](#) section is the reference documentation of the event loop APIs;
- The [Callback Handles](#) section documents the [Handle](#) and [TimerHandle](#) instances which are returned from scheduling methods such as `loop.call_soon()` and `loop.call_later()`;
- The [Server Objects](#) section documents types returned from event loop methods like `loop.create_server()`;
- The [Event Loop Implementations](#) section documents the [SelectorEventLoop](#) and [ProactorEventLoop](#) classes;
- The [Examples](#) section showcases how to work with some event loop APIs.

## Event Loop Methods

Event loops have **low-level** APIs for the following:

- [Running and stopping the loop](#)
- [Scheduling callbacks](#)
- [Scheduling delayed callbacks](#)
- [Creating Futures and Tasks](#)
- [Opening network connections](#)
- [Creating network servers](#)
- [Transferring files](#)
- [TLS Upgrade](#)
- [Watching file descriptors](#)
- [Working with socket objects directly](#)
- [DNS](#)
- [Working with pipes](#)
- [Unix signals](#)
- [Executing code in thread or process pools](#)

- [Error Handling API](#)
- [Enabling debug mode](#)
- [Running Subprocesses](#)

## Running and stopping the loop

`loop.run_until_complete(future)`

Run until the *future* (an instance of **Future**) has completed.

If the argument is a **coroutine object** it is implicitly scheduled to run as a **`asyncio.Task`**.

Return the Future's result or raise its exception.

`loop.run_forever()`

Run the event loop until **`stop()`** is called.

If **`stop()`** is called before **`run_forever()`** is called, the loop will poll the I/O selector once with a timeout of zero, run all callbacks scheduled in response to I/O events (and those that were already scheduled), and then exit.

If **`stop()`** is called while **`run_forever()`** is running, the loop will run the current batch of callbacks and then exit. Note that new callbacks scheduled by callbacks will not run in this case; instead, they will run the next time **`run_forever()`** or **`run_until_complete()`** is called.

`loop.stop()`

Stop the event loop.

`loop.is_running()`

Return `True` if the event loop is currently running.

`loop.is_closed()`

Return `True` if the event loop was closed.

`loop.close()`

Close the event loop.

The loop must not be running when this function is called. Any pending callbacks will be discarded.

This method clears all queues and shuts down the executor, but does not wait for the executor to finish.

This method is idempotent and irreversible. No other methods should be called after the event loop is closed.

*coroutine* `loop.shutdown_asyncgens()`

Schedule all currently open [asynchronous generator](#) objects to close with an `aclose()` call. After calling this method, the event loop will issue a warning if a new asynchronous generator is iterated. This should be used to reliably finalize all scheduled asynchronous generators.

Note that there is no need to call this function when `asyncio.run()` is used.

Example:

```
try:
    loop.run_forever()
finally:
    loop.run_until_complete(loop.shutdown_asyncgens())
    loop.close()
```

*New in version 3.6.*

*coroutine* `loop.shutdown_default_executor()`

Schedule the closure of the default executor and wait for it to join all of the threads in the [ThreadPoolExecutor](#). Once this method has been called, using the default executor with `loop.run_in_executor()` will raise a [RuntimeError](#).

**Note**

Do not call this method when using `asyncio.run()`, as the latter handles default executor shutdown automatically.

*New in version 3.9.*

## Scheduling callbacks

`loop.call_soon(callback, *args, context=None)`

Schedule the *callback* `callback` to be called with *args* arguments at the next iteration of the event loop.

Return an instance of `asyncio.Handle`, which can be used later to cancel the callback.

Callbacks are called in the order in which they are registered. Each callback will be called exactly once.

The optional keyword-only *context* argument specifies a custom `contextvars.Context` for the *callback* to run in. Callbacks use the current context when no *context* is provided.

Unlike `call_soon_threadsafe()`, this method is not thread-safe.

`loop.call_soon_threadsafe(callback, *args, context=None)`

A thread-safe variant of `call_soon()`. When scheduling callbacks from another thread, this function *must* be used, since `call_soon()` is not thread-safe.

Raises `RuntimeError` if called on a loop that's been closed. This can happen on a secondary thread when the main application is shutting down.

See the [concurrency and multithreading](#) section of the documentation.

*Changed in version 3.7:* The *context* keyword-only parameter was

added. See [PEP 567](https://peps.python.org/pep-0567/) [https://peps.python.org/pep-0567/] for more details.

## Note

Most `asyncio` scheduling functions don't allow passing keyword arguments. To do that, use `functools.partial()`:

```
# will schedule "print("Hello", flush=True)"
loop.call_soon(
    functools.partial(print, "Hello", flush=True))
```

Using partial objects is usually more convenient than using lambdas, as `asyncio` can render partial objects better in debug and error messages.

## Scheduling delayed callbacks

Event loop provides mechanisms to schedule callback functions to be called at some point in the future. Event loop uses monotonic clocks to track time.

```
loop.call_later(delay, callback, *args, context=None)
```

Schedule *callback* to be called after the given *delay* number of seconds (can be either an int or a float).

An instance of `asyncio.TimerHandle` is returned which can be used to cancel the callback.

*callback* will be called exactly once. If two callbacks are scheduled for exactly the same time, the order in which they are called is undefined.

The optional positional *args* will be passed to the callback when it is called. If you want the callback to be called with keyword arguments use `functools.partial()`.

An optional keyword-only *context* argument allows specifying a custom `contextvars.Context` for the *callback* to run in. The current context is used when no *context* is provided.

*Changed in version 3.7:* The *context* keyword-only parameter was added. See [PEP 567](https://peps.python.org/pep-0567/) [https://peps.python.org/pep-0567/] for more details.

*Changed in version 3.8:* In Python 3.7 and earlier with the default event loop implementation, the *delay* could not exceed one day. This has been fixed in Python 3.8.

`loop.call_at(when, callback, *args, context=None)`

Schedule *callback* to be called at the given absolute timestamp *when* (an int or a float), using the same time reference as `loop.time()`.

This method's behavior is the same as `call_later()`.

An instance of `asyncio.TimerHandle` is returned which can be used to cancel the callback.

*Changed in version 3.7:* The *context* keyword-only parameter was added. See [PEP 567](https://peps.python.org/pep-0567/) [https://peps.python.org/pep-0567/] for more details.

*Changed in version 3.8:* In Python 3.7 and earlier with the default event loop implementation, the difference between *when* and the current time could not exceed one day. This has been fixed in Python 3.8.

`loop.time()`

Return the current time, as a `float` value, according to the event loop's internal monotonic clock.

## Note

*Changed in version 3.8:* In Python 3.7 and earlier timeouts (relative *delay* or absolute *when*) should not exceed one day. This has been fixed in Python 3.8.

**See also**

The `asyncio.sleep()` function.

## Creating Futures and Tasks

`loop.create_future()`

Create an `asyncio.Future` object attached to the event loop.

This is the preferred way to create Futures in asyncio. This lets third-party event loops provide alternative implementations of the Future object (with better performance or instrumentation).

*New in version 3.5.2.*

`loop.create_task(coro, *, name=None, context=None)`

Schedule the execution of `coroutine coro`. Return a `Task` object.

Third-party event loops can use their own subclass of `Task` for interoperability. In this case, the result type is a subclass of `Task`.

If the `name` argument is provided and not `None`, it is set as the name of the task using `Task.set_name()`.

An optional keyword-only `context` argument allows specifying a custom `contextvars.Context` for the `coro` to run in. The current context copy is created when no `context` is provided.

*Changed in version 3.8:* Added the `name` parameter.

*Changed in version 3.11:* Added the `context` parameter.

`loop.set_task_factory(factory)`

Set a task factory that will be used by `loop.create_task()`.

If *factory* is `None` the default task factory will be set. Otherwise, *factory* must be a *callable* with the signature matching `(loop, coro, context=None)`, where *loop* is a reference to the active event loop, and *coro* is a coroutine object. The callable must return a `asyncio.Future`-compatible object.

`loop.get_task_factory()`

Return a task factory or `None` if the default one is in use.

## Opening network connections

*coroutine* `loop.create_connection(protocol_factory, host=None, port=None, *, ssl=None, family=0, proto=0, flags=0, sock=None, local_addr=None, server_hostname=None, ssl_handshake_timeout=None, ssl_shutdown_timeout=None, happy_eyeballs_delay=None, interleave=None)`

Open a streaming transport connection to a given address specified by *host* and *port*.

The socket family can be either `AF_INET` or `AF_INET6` depending on *host* (or the *family* argument, if provided).

The socket type will be `SOCK_STREAM`.

*protocol\_factory* must be a callable returning an `asyncio.protocol` implementation.

This method will try to establish the connection in the background. When successful, it returns a `(transport, protocol)` pair.

The chronological synopsis of the underlying operation is as follows:

1. The connection is established and a `transport` is created for it.
2. *protocol\_factory* is called without arguments and is expected to return a `protocol` instance.

3. The protocol instance is coupled with the transport by calling its `connection_made()` method.
4. A `(transport, protocol)` tuple is returned on success.

The created transport is an implementation-dependent bidirectional stream.

Other arguments:

- *ssl*: if given and not false, a SSL/TLS transport is created (by default a plain TCP transport is created). If *ssl* is a `ssl.SSLContext` object, this context is used to create the transport; if *ssl* is `True`, a default context returned from `ssl.create_default_context()` is used.

**See also**

[SSL/TLS security considerations](#)

- *server\_hostname* sets or overrides the hostname that the target server's certificate will be matched against. Should only be passed if *ssl* is not `None`. By default the value of the *host* argument is used. If *host* is empty, there is no default and you must pass a value for *server\_hostname*. If *server\_hostname* is an empty string, hostname matching is disabled (which is a serious security risk, allowing for potential man-in-the-middle attacks).
- *family*, *proto*, *flags* are the optional address family, protocol and flags to be passed through to `getaddrinfo()` for *host* resolution. If given, these should all be integers from the corresponding `socket` module constants.
- *happy\_eyeballs\_delay*, if given, enables Happy Eyeballs for this connection. It should be a floating-point number representing the amount of time in seconds to wait for a connection attempt to complete, before starting the next attempt in parallel. This is the "Connection Attempt Delay" as defined in [RFC 8305](#)

[<https://datatracker.ietf.org/doc/html/rfc8305.html>]. A sensible default value recommended by the RFC is `0.25` (250 milliseconds).

- *interleave* controls address reordering when a host name resolves to multiple IP addresses. If `0` or unspecified, no reordering is done, and addresses are tried in the order returned by `getaddrinfo()`. If a positive integer is specified, the addresses are interleaved by address family, and the given integer is interpreted as “First Address Family Count” as defined in [RFC 8305](https://datatracker.ietf.org/doc/html/rfc8305.html) [<https://datatracker.ietf.org/doc/html/rfc8305.html>]. The default is `0` if *happy\_eyeballs\_delay* is not specified, and `1` if it is.
- *sock*, if given, should be an existing, already connected `socket.socket` object to be used by the transport. If *sock* is given, none of *host*, *port*, *family*, *proto*, *flags*, *happy\_eyeballs\_delay*, *interleave* and *local\_addr* should be specified.

### Note

The *sock* argument transfers ownership of the socket to the transport created. To close the socket, call the transport’s `close()` method.

- *local\_addr*, if given, is a `(local_host, local_port)` tuple used to bind the socket locally. The *local\_host* and *local\_port* are looked up using `getaddrinfo()`, similarly to *host* and *port*.
- *ssl\_handshake\_timeout* is (for a TLS connection) the time in seconds to wait for the TLS handshake to complete before aborting the connection. `60.0` seconds if `None` (default).
- *ssl\_shutdown\_timeout* is the time in seconds to wait for the SSL shutdown to complete before aborting the connection. `30.0` seconds if `None` (default).

*Changed in version 3.5:* Added support for SSL/TLS in `ProactorEventLoop`.

*Changed in version 3.6:* The socket option `TCP_NODELAY` is set by default for all TCP connections.

*Changed in version 3.7:* Added the `ssl_handshake_timeout` parameter.

*Changed in version 3.8:* Added the `happy_eyeballs_delay` and `interleave` parameters.

Happy Eyeballs Algorithm: Success with Dual-Stack Hosts. When a server's IPv4 path and protocol are working, but the server's IPv6 path and protocol are not working, a dual-stack client application experiences significant connection delay compared to an IPv4-only client. This is undesirable because it causes the dual-stack client to have a worse user experience. This document specifies requirements for algorithms that reduce this user-visible delay and provides an algorithm.

For more information: <https://datatracker.ietf.org/doc/html/rfc6555>

*Changed in version 3.11:* Added the `ssl_shutdown_timeout` parameter.

## See also

The `open_connection()` function is a high-level alternative API. It returns a pair of (`StreamReader`, `StreamWriter`) that can be used directly in `async/await` code.

```
coroutine loop.create_datagram_endpoint(protocol_factory,  
local_addr=None, remote_addr=None, *, family=0, proto=0,  
flags=0, reuse_port=None, allow_broadcast=None, sock=None)
```

Create a datagram connection.

The socket family can be either `AF_INET`, `AF_INET6`, or `AF_UNIX`, depending on *host* (or the *family* argument, if provided).

The socket type will be `SOCK_DGRAM`.

*protocol\_factory* must be a callable returning a `protocol` implementation.

A tuple of `(transport, protocol)` is returned on success.

Other arguments:

- *local\_addr*, if given, is a `(local_host, local_port)` tuple used to bind the socket locally. The *local\_host* and *local\_port* are looked up using `getaddrinfo()`.
- *remote\_addr*, if given, is a `(remote_host, remote_port)` tuple used to connect the socket to a remote address. The *remote\_host* and *remote\_port* are looked up using `getaddrinfo()`.
- *family*, *proto*, *flags* are the optional address family, protocol and flags to be passed through to `getaddrinfo()` for *host* resolution. If given, these should all be integers from the corresponding `socket` module constants.
- *reuse\_port* tells the kernel to allow this endpoint to be bound to the same port as other existing endpoints are bound to, so long as they all set this flag when being created. This option is not supported on Windows and some Unixes. If the `SO_REUSEPORT` constant is not defined then this capability is unsupported.
- *allow\_broadcast* tells the kernel to allow this endpoint to send messages to the broadcast address.
- *sock* can optionally be specified in order to use a preexisting, already connected, `socket.socket`

object to be used by the transport. If specified, *local\_addr* and *remote\_addr* should be omitted (must be **None**).

### Note

The *sock* argument transfers ownership of the socket to the transport created. To close the socket, call the transport's **close()** method.

See [UDP echo client protocol](#) and [UDP echo server protocol](#) examples.

*Changed in version 3.4.4:* The *family*, *proto*, *flags*, *reuse\_address*, *reuse\_port*, *allow\_broadcast*, and *sock* parameters were added.

*Changed in version 3.8.1:* The *reuse\_address* parameter is no longer supported, as using **SO\_REUSEADDR** poses a significant security concern for UDP. Explicitly passing *reuse\_address=True* will raise an exception.

When multiple processes with differing UIDs assign sockets to an identical UDP socket address with **SO\_REUSEADDR**, incoming packets can become randomly distributed among the sockets.

For supported platforms, *reuse\_port* can be used as a replacement for similar functionality. With *reuse\_port*, **SO\_REUSEPORT** is used instead, which specifically prevents processes with differing UIDs from assigning sockets to the same socket address.

*Changed in version 3.8:* Added support for Windows.

*Changed in version 3.11:* The *reuse\_address* parameter, disabled since Python 3.9.0, 3.8.1, 3.7.6 and 3.6.10, has been entirely removed.

```
coroutine loop.create_unix_connection(protocol_factory, path=None,  
*, ssl=None, sock=None, server_hostname=None,
```

*ssl\_handshake\_timeout=None, ssl\_shutdown\_timeout=None)*

Create a Unix connection.

The socket family will be **AF\_UNIX**; socket type will be **SOCK\_STREAM**.

A tuple of (*transport*, *protocol*) is returned on success.

*path* is the name of a Unix domain socket and is required, unless a *sock* parameter is specified. Abstract Unix sockets, **str**, **bytes**, and **Path** paths are supported.

See the documentation of the **loop.create\_connection()** method for information about arguments to this method.

**Availability:** Unix.

*Changed in version 3.7:* Added the *ssl\_handshake\_timeout* parameter. The *path* parameter can now be a **path-like object**.

*Changed in version 3.11:* Added the *ssl\_shutdown\_timeout* parameter.

## Creating network servers

*coroutine loop.create\_server(protocol\_factory, host=None, port=None, \*, family=socket.AF\_UNSPEC, flags=socket.AI\_PASSIVE, sock=None, backlog=100, ssl=None, reuse\_address=None, reuse\_port=None, ssl\_handshake\_timeout=None, ssl\_shutdown\_timeout=None, start\_serving=True)*

Create a TCP server (socket type **SOCK\_STREAM**) listening on *port* of the *host* address.

Returns a **Server** object.

Arguments:

- *protocol\_factory* must be a callable returning a **protocol**

implementation.

- The *host* parameter can be set to several types which determine where the server would be listening:
  - If *host* is a string, the TCP server is bound to a single network interface specified by *host*.
  - If *host* is a sequence of strings, the TCP server is bound to all network interfaces specified by the sequence.
  - If *host* is an empty string or `None`, all interfaces are assumed and a list of multiple sockets will be returned (most likely one for IPv4 and another one for IPv6).
- The *port* parameter can be set to specify which port the server should listen on. If `0` or `None` (the default), a random unused port will be selected (note that if *host* resolves to multiple network interfaces, a different random port will be selected for each interface).
- *family* can be set to either `socket.AF_INET` or `AF_INET6` to force the socket to use IPv4 or IPv6. If not set, the *family* will be determined from host name (defaults to `AF_UNSPEC`).
- *flags* is a bitmask for `getaddrinfo()`.
- *sock* can optionally be specified in order to use a preexisting socket object. If specified, *host* and *port* must not be specified.

### Note

The *sock* argument transfers ownership of the socket to the server created. To close the socket, call the server's `close()` method.

- *backlog* is the maximum number of queued connections passed to `listen()` (defaults to 100).

- `ssl` can be set to an `SSLContext` instance to enable TLS over the accepted connections.
- `reuse_address` tells the kernel to reuse a local socket in `TIME_WAIT` state, without waiting for its natural timeout to expire. If not specified will automatically be set to `True` on Unix.
- `reuse_port` tells the kernel to allow this endpoint to be bound to the same port as other existing endpoints are bound to, so long as they all set this flag when being created. This option is not supported on Windows.
- `ssl_handshake_timeout` is (for a TLS server) the time in seconds to wait for the TLS handshake to complete before aborting the connection. `60.0` seconds if `None` (default).
- `ssl_shutdown_timeout` is the time in seconds to wait for the SSL shutdown to complete before aborting the connection. `30.0` seconds if `None` (default).
- `start_serving` set to `True` (the default) causes the created server to start accepting connections immediately. When set to `False`, the user should await on `Server.start_serving()` or `Server.serve_forever()` to make the server to start accepting connections.

*Changed in version 3.5:* Added support for SSL/TLS in `ProactorEventLoop`.

*Changed in version 3.5.1:* The `host` parameter can be a sequence of strings.

*Changed in version 3.6:* Added `ssl_handshake_timeout` and `start_serving` parameters. The socket option `TCP_NODELAY` is set by default for all TCP connections.

*Changed in version 3.11:* Added the `ssl_shutdown_timeout` parameter.

## See also

The `start_server()` function is a higher-level alternative API that returns a pair of `StreamReader` and `StreamWriter` that can be used in an `async/await` code.

```
coroutine loop.create_unix_server(protocol_factory, path=None, *,
sock=None, backlog=100, ssl=None, ssl_handshake_timeout=None,
ssl_shutdown_timeout=None, start_serving=True)
```

Similar to `loop.create_server()` but works with the `AF_UNIX` socket family.

`path` is the name of a Unix domain socket, and is required, unless a `sock` argument is provided. Abstract Unix sockets, `str`, `bytes`, and `Path` paths are supported.

See the documentation of the `loop.create_server()` method for information about arguments to this method.

**Availability:** Unix.

*Changed in version 3.7:* Added the `ssl_handshake_timeout` and `start_serving` parameters. The `path` parameter can now be a `Path` object.

*Changed in version 3.11:* Added the `ssl_shutdown_timeout` parameter.

```
coroutine loop.connect_accepted_socket(protocol_factory, sock, *,
ssl=None, ssl_handshake_timeout=None, ssl_shutdown_timeout=None)
```

Wrap an already accepted connection into a transport/protocol pair.

This method can be used by servers that accept connections outside of `asyncio` but that use `asyncio` to handle them.

Parameters:

- `protocol_factory` must be a callable returning a `protocol`

implementation.

- `sock` is a preexisting socket object returned from `socket.accept()`.

### Note

The `sock` argument transfers ownership of the socket to the transport created. To close the socket, call the transport's `close()` method.

- `ssl` can be set to an `SSLContext` to enable SSL over the accepted connections.
- `ssl_handshake_timeout` is (for an SSL connection) the time in seconds to wait for the SSL handshake to complete before aborting the connection. `60.0` seconds if `None` (default).
- `ssl_shutdown_timeout` is the time in seconds to wait for the SSL shutdown to complete before aborting the connection. `30.0` seconds if `None` (default).

Returns a `(transport, protocol)` pair.

*New in version 3.5.3.*

*Changed in version 3.7:* Added the `ssl_handshake_timeout` parameter.

*Changed in version 3.11:* Added the `ssl_shutdown_timeout` parameter.

## Transferring files

```
coroutine loop.sendfile(transport, file, offset=0, count=None, *,  
fallback=True)
```

Send a *file* over a *transport*. Return the total number of bytes sent.

The method uses high-performance `os.sendfile()` if available.

*file* must be a regular file object opened in binary mode.

*offset* tells from where to start reading the file. If specified, *count* is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is always updated, even when this method raises an error, and `file.tell()` can be used to obtain the actual number of bytes sent.

*fallback* set to `True` makes asyncio to manually read and send the file when the platform does not support the sendfile system call (e.g. Windows or SSL socket on Unix).

Raise `SendfileNotAvailableError` if the system does not support the *sendfile* syscall and *fallback* is `False`.

*New in version 3.7.*

## TLS Upgrade

```
coroutine loop.start_tls(transport, protocol, sslcontext, *,
server_side=False, server_hostname=None,
ssl_handshake_timeout=None, ssl_shutdown_timeout=None)
```

Upgrade an existing transport-based connection to TLS.

Create a TLS coder/decoder instance and insert it between the *transport* and the *protocol*. The coder/decoder implements both *transport*-facing protocol and *protocol*-facing transport.

Return the created two-interface instance. After *await*, the *protocol* must stop using the original *transport* and communicate with the returned object only because the coder caches *protocol*-side data and sporadically exchanges extra TLS session packets with *transport*.

In some situations (e.g. when the passed transport is already closing) this may return `None`.

Parameters:

- *transport* and *protocol* instances that methods like `create_server()` and `create_connection()` return.
- *sslcontext*: a configured instance of `SSLContext`.
- *server\_side* pass `True` when a server-side connection is being upgraded (like the one created by `create_server()`).
- *server\_hostname*: sets or overrides the host name that the target server's certificate will be matched against.
- *ssl\_handshake\_timeout* is (for a TLS connection) the time in seconds to wait for the TLS handshake to complete before aborting the connection. `60.0` seconds if `None` (default).
- *ssl\_shutdown\_timeout* is the time in seconds to wait for the SSL shutdown to complete before aborting the connection. `30.0` seconds if `None` (default).

*New in version 3.7.*

*Changed in version 3.11:* Added the *ssl\_shutdown\_timeout* parameter.

## Watching file descriptors

`loop.add_reader(fd, callback, *args)`

Start monitoring the *fd* file descriptor for read availability and invoke *callback* with the specified arguments once *fd* is available for reading.

`loop.remove_reader(fd)`

Stop monitoring the *fd* file descriptor for read availability. Returns `True` if *fd* was previously being monitored for reads.

`loop.add_writer(fd, callback, *args)`

Start monitoring the *fd* file descriptor for write availability and invoke *callback* with the specified arguments once *fd* is available for writing.

Use `functools.partial()` to pass keyword arguments to *callback*.

`loop.remove_writer(fd)`

Stop monitoring the *fd* file descriptor for write availability. Returns `True` if *fd* was previously being monitored for writes.

See also [Platform Support](#) section for some limitations of these methods.

## Working with socket objects directly

In general, protocol implementations that use transport-based APIs such as `loop.create_connection()` and `loop.create_server()` are faster than implementations that work with sockets directly. However, there are some use cases when performance is not critical, and working with `socket` objects directly is more convenient.

*coroutine* `loop.sock_recv(sock, nbytes)`

Receive up to *nbytes* from *sock*. Asynchronous version of `socket.recv()`.

Return the received data as a bytes object.

*sock* must be a non-blocking socket.

*Changed in version 3.7:* Even though this method was always documented as a coroutine method, releases before Python 3.7 returned a `Future`. Since Python 3.7 this is an `async def` method.

*coroutine* `loop.sock_recv_into(sock, buf)`

Receive data from *sock* into the *buf* buffer. Modeled after the blocking `socket.recv_into()` method.

Return the number of bytes written to the buffer.

*sock* must be a non-blocking socket.

*New in version 3.7.*

*coroutine* `loop.sock_recvfrom(sock, bufsize)`

Receive a datagram of up to *bufsize* from *sock*. Asynchronous version of `socket.recvfrom()`.

Return a tuple of (received data, remote address).

*sock* must be a non-blocking socket.

*New in version 3.11.*

*coroutine* `loop.sock_recvfrom_into(sock, buf, nbytes=0)`

Receive a datagram of up to *nbytes* from *sock* into *buf*. Asynchronous version of `socket.recvfrom_into()`.

Return a tuple of (number of bytes received, remote address).

*sock* must be a non-blocking socket.

*New in version 3.11.*

*coroutine* `loop.sock_sendall(sock, data)`

Send *data* to the *sock* socket. Asynchronous version of `socket.sendall()`.

This method continues to send to the socket until either all data in *data* has been sent or an error occurs. `None` is returned on success. On error, an exception is raised. Additionally, there is no way to determine how much data, if any, was successfully processed by the receiving end of the connection.

*sock* must be a non-blocking socket.

*Changed in version 3.7:* Even though the method was always documented as a coroutine method, before Python 3.7 it returned a `Future`. Since Python 3.7, this is an `async def`

method.

*coroutine* `loop.sock_sendto(sock, data, address)`

Send a datagram from *sock* to *address*. Asynchronous version of `socket.sendto()`.

Return the number of bytes sent.

*sock* must be a non-blocking socket.

*New in version 3.11.*

*coroutine* `loop.sock_connect(sock, address)`

Connect *sock* to a remote socket at *address*.

Asynchronous version of `socket.connect()`.

*sock* must be a non-blocking socket.

*Changed in version 3.5.2:* *address* no longer needs to be resolved. `sock_connect` will try to check if the *address* is already resolved by calling `socket.inet_pton()`. If not, `loop.getaddrinfo()` will be used to resolve the *address*.

**See also**

`loop.create_connection()` and  
`asyncio.open_connection()`.

*coroutine* `loop.sock_accept(sock)`

Accept a connection. Modeled after the blocking `socket.accept()` method.

The socket must be bound to an address and listening for connections. The return value is a pair (*conn*, *address*) where *conn* is a *new* socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection.

*sock* must be a non-blocking socket.

*Changed in version 3.7:* Even though the method was always documented as a coroutine method, before Python 3.7 it returned a **Future**. Since Python 3.7, this is an `async def` method.

**See also**

`loop.create_server()` and `start_server()`.

*coroutine* `loop.sock_sendfile(sock, file, offset=0, count=None, *, fallback=True)`

Send a file using high-performance `os.sendfile` if possible. Return the total number of bytes sent.

Asynchronous version of `socket.sendfile()`.

*sock* must be a non-blocking `socket.SOCK_STREAM` `socket`.

*file* must be a regular file object open in binary mode.

*offset* tells from where to start reading the file. If specified, *count* is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is always updated, even when this method raises an error, and `file.tell()` can be used to obtain the actual number of bytes sent.

*fallback*, when set to `True`, makes asyncio manually read and send the file when the platform does not support the `sendfile` syscall (e.g. Windows or SSL socket on Unix).

Raise **SendfileNotAvailableError** if the system does not support `sendfile` syscall and *fallback* is `False`.

*sock* must be a non-blocking socket.

*New in version 3.7.*

## DNS

*coroutine* loop.getaddrinfo(*host*, *port*, \*, *family*=0, *type*=0, *proto*=0, *flags*=0)

Asynchronous version of `socket.getaddrinfo()`.

*coroutine* loop.getnameinfo(*sockaddr*, *flags*=0)

Asynchronous version of `socket.getnameinfo()`.

*Changed in version 3.7:* Both `getaddrinfo` and `getnameinfo` methods were always documented to return a coroutine, but prior to Python 3.7 they were, in fact, returning `asyncio.Future` objects. Starting with Python 3.7 both methods are coroutines.

## Working with pipes

*coroutine* loop.connect\_read\_pipe(*protocol\_factory*, *pipe*)

Register the read end of *pipe* in the event loop.

*protocol\_factory* must be a callable returning an `asyncio.Protocol` implementation.

*pipe* is a `file-like object`.

Return pair (*transport*, *protocol*), where *transport* supports the `ReadTransport` interface and *protocol* is an object instantiated by the *protocol\_factory*.

With `SelectorEventLoop` event loop, the *pipe* is set to non-blocking mode.

*coroutine* loop.connect\_write\_pipe(*protocol\_factory*, *pipe*)

Register the write end of *pipe* in the event loop.

*protocol\_factory* must be a callable returning an `asyncio.Protocol` implementation.

*pipe* is `file-like object`.

Return pair `(transport, protocol)`, where *transport* supports `WriteTransport` interface and *protocol* is an object instantiated by the *protocol\_factory*.

With `SelectorEventLoop` event loop, the *pipe* is set to non-blocking mode.

## Note

`SelectorEventLoop` does not support the above methods on Windows. Use `ProactorEventLoop` instead for Windows.

## See also

The `loop.subprocess_exec()` and `loop.subprocess_shell()` methods.

## Unix signals

`loop.add_signal_handler(signum, callback, *args)`

Set *callback* as the handler for the *signum* signal.

The callback will be invoked by *loop*, along with other queued callbacks and runnable coroutines of that event loop. Unlike signal handlers registered using `signal.signal()`, a callback registered with this function is allowed to interact with the event loop.

Raise `ValueError` if the signal number is invalid or uncatchable. Raise `RuntimeError` if there is a problem setting up the handler.

Use `functools.partial()` to pass keyword arguments to *callback*.

Like `signal.signal()`, this function must be invoked in the main thread.

`loop.remove_signal_handler(sig)`

Remove the handler for the *sig* signal.

Return `True` if the signal handler was removed, or `False` if no handler was set for the given signal.

[Availability](#): Unix.

## See also

The [signal](#) module.

## Executing code in thread or process pools

*awaitable* `loop.run_in_executor(executor, func, *args)`

Arrange for *func* to be called in the specified executor.

The *executor* argument should be an [concurrent.futures.Executor](#) instance. The default executor is used if *executor* is `None`.

Example:

```
import asyncio
import concurrent.futures

def blocking_io():
    # File operations (such as logging) can block the
    # event loop: run them in a thread pool.
    with open('/dev/urandom', 'rb') as f:
        return f.read(100)

def cpu_bound():
    # CPU-bound operations will block the event loop
    # in general it is preferable to run them in a
    # process pool.
    return sum(i * i for i in range(10 ** 7))
```

```

async def main():
    loop = asyncio.get_running_loop()

    ## Options:

    # 1. Run in the default loop's executor:
    result = await loop.run_in_executor(
        None, blocking_io)
    print('default thread pool', result)

    # 2. Run in a custom thread pool:
    with concurrent.futures.ThreadPoolExecutor() as pool:
        result = await loop.run_in_executor(
            pool, blocking_io)
        print('custom thread pool', result)

    # 3. Run in a custom process pool:
    with concurrent.futures.ProcessPoolExecutor() as pool:
        result = await loop.run_in_executor(
            pool, cpu_bound)
        print('custom process pool', result)

if __name__ == '__main__':
    asyncio.run(main())

```

Note that the entry point guard (`if __name__ == '__main__':`) is required for option 3 due to the peculiarities of [multiprocessing](#), which is used by [ProcessPoolExecutor](#). See [Safe importing of main module](#).

This method returns a [asyncio.Future](#) object.

Use [functools.partial\(\)](#) to pass keyword arguments to *func*.

*Changed in version 3.5.3:* [loop.run\\_in\\_executor\(\)](#) no longer configures the `max_workers` of the thread pool executor it creates, instead leaving it up to the thread pool executor ([ThreadPoolExecutor](#)) to set the default.

`loop.set_default_executor(executor)`

Set *executor* as the default executor used by `run_in_executor()`. *executor* must be an instance of `ThreadPoolExecutor`.

*Changed in version 3.11:* *executor* must be an instance of `ThreadPoolExecutor`.

## Error Handling API

Allows customizing how exceptions are handled in the event loop.

`loop.set_exception_handler(handler)`

Set *handler* as the new event loop exception handler.

If *handler* is `None`, the default exception handler will be set. Otherwise, *handler* must be a callable with the signature matching `(loop, context)`, where `loop` is a reference to the active event loop, and `context` is a `dict` object containing the details of the exception (see `call_exception_handler()` documentation for details about context).

`loop.get_exception_handler()`

Return the current exception handler, or `None` if no custom exception handler was set.

*New in version 3.5.2.*

`loop.default_exception_handler(context)`

Default exception handler.

This is called when an exception occurs and no exception handler is set. This can be called by a custom exception handler that wants to defer to the default handler behavior.

*context* parameter has the same meaning as in `call_exception_handler()`.

`loop.call_exception_handler(context)`

Call the current event loop exception handler.

*context* is a `dict` object containing the following keys (new keys may be introduced in future Python versions):

- ‘message’: Error message;
- ‘exception’ (optional): Exception object;
- ‘future’ (optional): `asyncio.Future` instance;
- ‘task’ (optional): `asyncio.Task` instance;
- ‘handle’ (optional): `asyncio.Handle` instance;
- ‘protocol’ (optional): `Protocol` instance;
- ‘transport’ (optional): `Transport` instance;
- ‘socket’ (optional): `socket.socket` instance;
- ‘asyncgen’ (optional): Asynchronous generator that caused the exception.

### Note

This method should not be overloaded in subclassed event loops. For custom exception handling, use the `set_exception_handler()` method.

## Enabling debug mode

`loop.get_debug()`

Get the debug mode (`bool`) of the event loop.

The default value is `True` if the environment variable `PYTHONASYNCIODEBUG` is set to a non-empty string, `False` otherwise.

`loop.set_debug(enabled: bool)`

Set the debug mode of the event loop.

*Changed in version 3.7:* The new [Python Development Mode](#)

can now also be used to enable the debug mode.

## See also

The [debug mode of asyncio](#).

## Running Subprocesses

Methods described in this subsections are low-level. In regular `async/await` code consider using the high-level [`asyncio.create\_subprocess\_shell\(\)`](#) and [`asyncio.create\_subprocess\_exec\(\)`](#) convenience functions instead.

### Note

On Windows, the default event loop [`ProactorEventLoop`](#) supports subprocesses, whereas [`SelectorEventLoop`](#) does not. See [Subprocess Support on Windows](#) for details.

```
coroutine loop.subprocess_exec(protocol_factory, *args,  
stdin=subprocess.PIPE, stdout=subprocess.PIPE,  
stderr=subprocess.PIPE, **kwargs)
```

Create a subprocess from one or more string arguments specified by *args*.

*args* must be a list of strings represented by:

- [`str`](#);
- or [`bytes`](#), encoded to the [filesystem encoding](#).

The first string specifies the program executable, and the remaining strings specify the arguments. Together, string arguments form the `argv` of the program.

This is similar to the standard library [`subprocess.Popen`](#) class called with `shell=False` and the list of strings passed as the first argument; however, where [`Popen`](#) takes a single

argument which is list of strings, *subprocess\_exec* takes multiple string arguments.

The *protocol\_factory* must be a callable returning a subclass of the `asyncio.SubprocessProtocol` class.

Other parameters:

- *stdin* can be any of these:
  - a file-like object representing a pipe to be connected to the subprocess's standard input stream using `connect_write_pipe()`
  - the `subprocess.PIPE` constant (default) which will create a new pipe and connect it,
  - the value `None` which will make the subprocess inherit the file descriptor from this process
  - the `subprocess.DEVNULL` constant which indicates that the special `os.devnull` file will be used
- *stdout* can be any of these:
  - a file-like object representing a pipe to be connected to the subprocess's standard output stream using `connect_write_pipe()`
  - the `subprocess.PIPE` constant (default) which will create a new pipe and connect it,
  - the value `None` which will make the subprocess inherit the file descriptor from this process
  - the `subprocess.DEVNULL` constant which indicates that the special `os.devnull` file will be used
- *stderr* can be any of these:
  - a file-like object representing a pipe to be connected to the subprocess's standard error stream using `connect_write_pipe()`
  - the `subprocess.PIPE` constant (default) which will create a new pipe and connect it,

- the value `None` which will make the subprocess inherit the file descriptor from this process
  - the `subprocess.DEVNULL` constant which indicates that the special `os.devnull` file will be used
  - the `subprocess.STDOUT` constant which will connect the standard error stream to the process' standard output stream
- All other keyword arguments are passed to `subprocess.Popen` without interpretation, except for *bufsize*, *universal\_newlines*, *shell*, *text*, *encoding* and *errors*, which should not be specified at all.

The `asyncio` subprocess API does not support decoding the streams as text. `bytes.decode()` can be used to convert the bytes returned from the stream to text.

See the constructor of the `subprocess.Popen` class for documentation on other arguments.

Returns a pair of `(transport, protocol)`, where *transport* conforms to the `asyncio.SubprocessTransport` base class and *protocol* is an object instantiated by the *protocol\_factory*.

```
coroutine loop.subprocess_shell(protocol_factory, cmd, *,
stdin=subprocess.PIPE, stdout=subprocess.PIPE,
stderr=subprocess.PIPE, **kwargs)
```

Create a subprocess from *cmd*, which can be a `str` or a `bytes` string encoded to the `filesystem encoding`, using the platform's "shell" syntax.

This is similar to the standard library `subprocess.Popen` class called with `shell=True`.

The *protocol\_factory* must be a callable returning a subclass of the `SubprocessProtocol` class.

See `subprocess_exec()` for more details about the remaining arguments.

Returns a pair of `(transport, protocol)`, where *transport* conforms to the `SubprocessTransport` base class and *protocol* is an object instantiated by the *protocol\_factory*.

## Note

It is the application's responsibility to ensure that all whitespace and special characters are quoted appropriately to avoid [shell injection](https://en.wikipedia.org/wiki/Shell_injection#Shell_injection) [https://en.wikipedia.org/wiki/Shell\_injection#Shell\_injection] vulnerabilities. The `shlex.quote()` function can be used to properly escape whitespace and special characters in strings that are going to be used to construct shell commands.

# Callback Handles

`class asyncio.Handle`

A callback wrapper object returned by `loop.call_soon()`, `loop.call_soon_threadsafe()`.

`cancel()`

Cancel the callback. If the callback has already been canceled or executed, this method has no effect.

`cancelled()`

Return `True` if the callback was cancelled.

*New in version 3.7.*

`class asyncio.TimerHandle`

A callback wrapper object returned by `loop.call_later()`, and `loop.call_at()`.

This class is a subclass of `Handle`.

`when()`

Return a scheduled callback time as `float` seconds.

The time is an absolute timestamp, using the same time reference as `loop.time()`.

*New in version 3.7.*

## Server Objects

Server objects are created by `loop.create_server()`, `loop.create_unix_server()`, `start_server()`, and `start_unix_server()` functions.

Do not instantiate the `Server` class directly.

`class asyncio.Server`

*Server* objects are asynchronous context managers. When used in an `async with` statement, it's guaranteed that the *Server* object is closed and not accepting new connections when the `async with` statement is completed:

```
srv = await loop.create_server(...)
```

```
async with srv:
    # some code
```

```
# At this point, srv is closed and no longer accept
```

*Changed in version 3.7:* *Server* object is an asynchronous context manager since Python 3.7.

`close()`

Stop serving: close listening sockets and set the `sockets` attribute to `None`.

The sockets that represent existing incoming client connections are left open.

The server is closed asynchronously, use the `wait_closed()` coroutine to wait until the server is closed.

### `get_loop()`

Return the event loop associated with the server object.

*New in version 3.7.*

### *coroutine* `start_serving()`

Start accepting connections.

This method is idempotent, so it can be called when the server is already serving.

The `start_serving` keyword-only parameter to `loop.create_server()` and `asyncio.start_server()` allows creating a `Server` object that is not accepting connections initially. In this case `Server.start_serving()`, or `Server.serve_forever()` can be used to make the `Server` start accepting connections.

*New in version 3.7.*

### *coroutine* `serve_forever()`

Start accepting connections until the coroutine is cancelled. Cancellation of `serve_forever` task causes the server to be closed.

This method can be called if the server is already accepting connections. Only one `serve_forever` task can exist per one `Server` object.

Example:

```
async def client_connected(reader, writer):
    # Communicate with the client with
    # reader/writer streams. For example:
```

```
await reader.readline()

async def main(host, port):
    srv = await asyncio.start_server(
        client_connected, host, port)
    await srv.serve_forever()

asyncio.run(main('127.0.0.1', 0))
```

*New in version 3.7.*

`is_serving()`

Return `True` if the server is accepting new connections.

*New in version 3.7.*

`coroutine wait_closed()`

Wait until the `close()` method completes.

`sockets`

List of socket-like objects,  
`asyncio.trsock.TransportSocket`, which the  
server is listening on.

*Changed in version 3.7:* Prior to Python 3.7  
`Server.sockets` used to return an internal list of  
server sockets directly. In 3.7 a copy of that list is  
returned.

## Event Loop Implementations

asyncio ships with two different event loop implementations:  
`SelectorEventLoop` and `ProactorEventLoop`.

By default asyncio is configured to use `SelectorEventLoop` on  
Unix and `ProactorEventLoop` on Windows.

### *class* `asyncio.SelectorEventLoop`

An event loop based on the `selectors` module.

Uses the most efficient *selector* available for the given platform. It is also possible to manually configure the exact selector implementation to be used:

```
import asyncio
import selectors

class MyPolicy(asyncio.DefaultEventLoopPolicy):
    def new_event_loop(self):
        selector = selectors.SelectSelector()
        return asyncio.SelectorEventLoop(selector)

asyncio.set_event_loop_policy(MyPolicy())
```

**Availability:** Unix, Windows.

### *class* `asyncio.ProactorEventLoop`

An event loop for Windows that uses “I/O Completion Ports” (IOCP).

**Availability:** Windows.

#### **See also**

[MSDN documentation on I/O Completion Ports](https://docs.microsoft.com/en-ca/windows/desktop/FileIO/i-o-completion-ports) [https://docs.microsoft.com/en-ca/windows/desktop/FileIO/i-o-completion-ports].

### *class* `asyncio.AbstractEventLoop`

Abstract base class for asyncio-compliant event loops.

The [Event Loop Methods](#) section lists all methods that an alternative implementation of `AbstractEventLoop` should have defined.

# Examples

Note that all examples in this section **purposefully** show how to use the low-level event loop APIs, such as `loop.run_forever()` and `loop.call_soon()`. Modern asyncio applications rarely need to be written this way; consider using the high-level functions like `asyncio.run()`.

## Hello World with `call_soon()`

An example using the `loop.call_soon()` method to schedule a callback. The callback displays "Hello World" and then stops the event loop:

```
import asyncio

def hello_world(loop):
    """A callback to print 'Hello World' and stop the event loop"""
    print('Hello World')
    loop.stop()

loop = asyncio.new_event_loop()

# Schedule a call to hello_world()
loop.call_soon(hello_world, loop)

# Blocking call interrupted by loop.stop()
try:
    loop.run_forever()
finally:
    loop.close()
```

### See also

A similar [Hello World](#) example created with a coroutine and the `run()` function.

## Display the current date with `call_later()`

An example of a callback displaying the current date every second. The callback uses the `loop.call_later()` method to reschedule itself after 5 seconds, and then stops the event loop:

```
import asyncio
import datetime

def display_date(end_time, loop):
    print(datetime.datetime.now())
    if (loop.time() + 1.0) < end_time:
        loop.call_later(1, display_date, end_time, loop)
    else:
        loop.stop()

loop = asyncio.new_event_loop()

# Schedule the first call to display_date()
end_time = loop.time() + 5.0
loop.call_soon(display_date, end_time, loop)

# Blocking call interrupted by loop.stop()
try:
    loop.run_forever()
finally:
    loop.close()
```

## See also

A similar [current date](#) example created with a coroutine and the [run\(\)](#) function.

## Watch a file descriptor for read events

Wait until a file descriptor received some data using the `loop.add_reader()` method and then close the event loop:

```
import asyncio
from socket import socketpair
```

```
# Create a pair of connected file descriptors
rsock, wsock = socketpair()

loop = asyncio.new_event_loop()

def reader():
    data = rsock.recv(100)
    print("Received:", data.decode())

    # We are done: unregister the file descriptor
    loop.remove_reader(rsock)

    # Stop the event loop
    loop.stop()

# Register the file descriptor for read event
loop.add_reader(rsock, reader)

# Simulate the reception of data from the network
loop.call_soon(wsock.send, 'abc'.encode())

try:
    # Run the event loop
    loop.run_forever()
finally:
    # We are done. Close sockets and the event loop.
    rsock.close()
    wsock.close()
    loop.close()
```

## See also

- A similar [example](#) using transports, protocols, and the [loop.create\\_connection\(\)](#) method.
- Another similar [example](#) using the high-level [asyncio.open\\_connection\(\)](#) function and streams.

## Set signal handlers for SIGINT and SIGTERM

(This `signals` example only works on Unix.)

Register handlers for signals **SIGINT** and **SIGTERM** using the `loop.add_signal_handler()` method:

```
import asyncio
import functools
import os
import signal

def ask_exit(signame, loop):
    print("got signal %s: exit" % signame)
    loop.stop()

async def main():
    loop = asyncio.get_running_loop()

    for signame in {'SIGINT', 'SIGTERM'}:
        loop.add_signal_handler(
            getattr(signal, signame),
            functools.partial(ask_exit, signame, loop))

    await asyncio.sleep(3600)

print("Event loop running for 1 hour, press Ctrl+C to in")
print(f"pid {os.getpid()}: send SIGINT or SIGTERM to exit")

asyncio.run(main())
```

# Futures

**Source code:** [Lib/asyncio/futures.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/futures.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/futures.py], [Lib/asyncio/base\\_futures.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/base_futures.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/base\_futures.py]

---

*Future* objects are used to bridge **low-level callback-based code** with high-level `async/await` code.

## Future Functions

`asyncio.isfuture(obj)`

Return `True` if *obj* is either of:

- an instance of `asyncio.Future`,
- an instance of `asyncio.Task`,
- a Future-like object with a `_asyncio_future_blocking` attribute.

*New in version 3.5.*

`asyncio.ensure_future(obj, *, loop=None)`

Return:

- *obj* argument as is, if *obj* is a `Future`, a `Task`, or a Future-like object (`isfuture()` is used for the test.)
- a `Task` object wrapping *obj*, if *obj* is a coroutine (`iscoroutine()` is used for the test); in this case the coroutine will be scheduled by `ensure_future()`.
- a `Task` object that would await on *obj*, if *obj* is an awaitable (`inspect.isawaitable()` is used for the test.)

If *obj* is neither of the above a `TypeError` is raised.

## Important

See also the `create_task()` function which is the preferred way for creating new Tasks.

Save a reference to the result of this function, to avoid a task disappearing mid-execution.

*Changed in version 3.5.1:* The function accepts any [awaitable](#) object.

*Deprecated since version 3.10:* Deprecation warning is emitted if *obj* is not a Future-like object and *loop* is not specified and there is no running event loop.

```
asyncio.wrap_future(future, *, loop=None)
```

Wrap a `concurrent.futures.Future` object in a `asyncio.Future` object.

*Deprecated since version 3.10:* Deprecation warning is emitted if *future* is not a Future-like object and *loop* is not specified and there is no running event loop.

## Future Object

```
class asyncio.Future(*, loop=None)
```

A Future represents an eventual result of an asynchronous operation. Not thread-safe.

Future is an [awaitable](#) object. Coroutines can await on Future objects until they either have a result or an exception set, or until they are cancelled. A Future can be awaited multiple times and the result is same.

Typically Futures are used to enable low-level callback-based code (e.g. in protocols implemented using [asyncio transports](#)) to interoperate with high-level `async/await` code.

The rule of thumb is to never expose Future objects in user-facing APIs, and the recommended way to create a Future

object is to call `loop.create_future()`. This way alternative event loop implementations can inject their own optimized implementations of a Future object.

*Changed in version 3.7:* Added support for the `contextvars` module.

*Deprecated since version 3.10:* Deprecation warning is emitted if `loop` is not specified and there is no running event loop.

`result()`

Return the result of the Future.

If the Future is *done* and has a result set by the `set_result()` method, the result value is returned.

If the Future is *done* and has an exception set by the `set_exception()` method, this method raises the exception.

If the Future has been *cancelled*, this method raises a `CancelledError` exception.

If the Future's result isn't yet available, this method raises a `InvalidStateError` exception.

`set_result(result)`

Mark the Future as *done* and set its result.

Raises a `InvalidStateError` error if the Future is already *done*.

`set_exception(exception)`

Mark the Future as *done* and set an exception.

Raises a `InvalidStateError` error if the Future is already *done*.

`done()`

Return `True` if the Future is *done*.

A Future is *done* if it was *cancelled* or if it has a result or an exception set with `set_result()` or `set_exception()` calls.

`cancelled()`

Return `True` if the Future was *cancelled*.

The method is usually used to check if a Future is not *cancelled* before setting a result or an exception for it:

```
if not fut.cancelled():
    fut.set_result(42)
```

`add_done_callback(callback, *, context=None)`

Add a callback to be run when the Future is *done*.

The *callback* is called with the Future object as its only argument.

If the Future is already *done* when this method is called, the callback is scheduled with `loop.call_soon()`.

An optional keyword-only *context* argument allows specifying a custom `contextvars.Context` for the *callback* to run in. The current context is used when no *context* is provided.

`functools.partial()` can be used to pass parameters to the callback, e.g.:

```
# Call 'print("Future:", fut)' when "fut" is done
fut.add_done_callback(
    functools.partial(print, "Future:"))
```

*Changed in version 3.7:* The *context* keyword-only parameter was added. See [PEP 567](https://peps.python.org/pep-0567/) [https://peps.python.org/pep-0567/] for more details.

`remove_done_callback(callback)`

Remove *callback* from the callbacks list.

Returns the number of callbacks removed, which is typically 1, unless a callback was added more than once.

`cancel(msg=None)`

Cancel the Future and schedule callbacks.

If the Future is already *done* or *cancelled*, return `False`. Otherwise, change the Future's state to *cancelled*, schedule the callbacks, and return `True`.

*Changed in version 3.9:* Added the *msg* parameter.

`exception()`

Return the exception that was set on this Future.

The exception (or `None` if no exception was set) is returned only if the Future is *done*.

If the Future has been *cancelled*, this method raises a **CancelledError** exception.

If the Future isn't *done* yet, this method raises an **InvalidStateError** exception.

`get_loop()`

Return the event loop the Future object is bound to.

*New in version 3.7.*

This example creates a Future object, creates and schedules an asynchronous Task to set result for the Future, and waits until the Future has a result:

```
async def set_after(fut, delay, value):  
    # Sleep for *delay* seconds.
```

```

await asyncio.sleep(delay)

# Set *value* as a result of *fut* Future.
fut.set_result(value)

async def main():
    # Get the current event loop.
    loop = asyncio.get_running_loop()

    # Create a new Future object.
    fut = loop.create_future()

    # Run "set_after()" coroutine in a parallel Task.
    # We are using the low-level "loop.create_task()" AF
    # we already have a reference to the event loop at h
    # Otherwise we could have just used "asyncio.create_
    loop.create_task(
        set_after(fut, 1, '... world'))

    print('hello ...')

    # Wait until *fut* has a result (1 second) and print
    print(await fut)

asyncio.run(main())

```

## Important

The Future object was designed to mimic **`concurrent.futures.Future`**. Key differences include:

- unlike asyncio Futures, **`concurrent.futures.Future`** instances cannot be awaited.
- **`asyncio.Future.result()`** and **`asyncio.Future.exception()`** do not accept the *timeout* argument.
- **`asyncio.Future.result()`** and **`asyncio.Future.exception()`** raise an **`InvalidStateError`** exception when the Future is not

*done.*

- Callbacks registered with `asyncio.Future.add_done_callback()` are not called immediately. They are scheduled with `loop.call_soon()` instead.
- `asyncio.Future` is not compatible with the `concurrent.futures.wait()` and `concurrent.futures.as_completed()` functions.
- `asyncio.Future.cancel()` accepts an optional `msg` argument, but `concurrent.futures.cancel()` does not.

# Transports and Protocols

## Preface

Transports and Protocols are used by the **low-level** event loop APIs such as `loop.create_connection()`. They use callback-based programming style and enable high-performance implementations of network or IPC protocols (e.g. HTTP).

Essentially, transports and protocols should only be used in libraries and frameworks and never in high-level asyncio applications.

This documentation page covers both [Transports](#) and [Protocols](#).

## Introduction

At the highest level, the transport is concerned with *how* bytes are transmitted, while the protocol determines *which* bytes to transmit (and to some extent when).

A different way of saying the same thing: a transport is an abstraction for a socket (or similar I/O endpoint) while a protocol is an abstraction for an application, from the transport's point of view.

Yet another view is the transport and protocol interfaces together define an abstract interface for using network I/O and interprocess I/O.

There is always a 1:1 relationship between transport and protocol objects: the protocol calls transport methods to send data, while the transport calls protocol methods to pass it data that has been received.

Most of connection oriented event loop methods (such as `loop.create_connection()`) usually accept a *protocol factory*

argument used to create a *Protocol* object for an accepted connection, represented by a *Transport* object. Such methods usually return a tuple of `(transport, protocol)`.

## Contents

This documentation page contains the following sections:

- The [Transports](#) section documents asyncio [BaseTransport](#), [ReadTransport](#), [WriteTransport](#), [Transport](#), [DatagramTransport](#), and [SubprocessTransport](#) classes.
- The [Protocols](#) section documents asyncio [BaseProtocol](#), [Protocol](#), [BufferedProtocol](#), [DatagramProtocol](#), and [SubprocessProtocol](#) classes.
- The [Examples](#) section showcases how to work with transports, protocols, and low-level event loop APIs.

## Transports

**Source code:** [Lib/asyncio/transports.py](#) [<https://github.com/python/cpython/tree/3.11/Lib/asyncio/transports.py>]

---

Transports are classes provided by [asyncio](#) in order to abstract various kinds of communication channels.

Transport objects are always instantiated by an [asyncio event loop](#).

asyncio implements transports for TCP, UDP, SSL, and subprocess pipes. The methods available on a transport depend on the transport's kind.

The transport classes are [not thread safe](#).

### Transports Hierarchy

`class asyncio.BaseTransport`

Base class for all transports. Contains methods that all asyncio

transports share.

*class* `asyncio.WriteTransport(BaseTransport)`

A base transport for write-only connections.

Instances of the *WriteTransport* class are returned from the `loop.connect_write_pipe()` event loop method and are also used by subprocess-related methods like `loop.subprocess_exec()`.

*class* `asyncio.ReadTransport(BaseTransport)`

A base transport for read-only connections.

Instances of the *ReadTransport* class are returned from the `loop.connect_read_pipe()` event loop method and are also used by subprocess-related methods like `loop.subprocess_exec()`.

*class* `asyncio.Transport(WriteTransport, ReadTransport)`

Interface representing a bidirectional transport, such as a TCP connection.

The user does not instantiate a transport directly; they call a utility function, passing it a protocol factory and other information necessary to create the transport and protocol.

Instances of the *Transport* class are returned from or used by event loop methods like `loop.create_connection()`, `loop.create_unix_connection()`, `loop.create_server()`, `loop.sendfile()`, etc.

*class* `asyncio.DatagramTransport(BaseTransport)`

A transport for datagram (UDP) connections.

Instances of the *DatagramTransport* class are returned from the `loop.create_datagram_endpoint()` event loop method.

*class* `asyncio.SubprocessTransport(BaseTransport)`

An abstraction to represent a connection between a parent and its child OS process.

Instances of the *SubprocessTransport* class are returned from event loop methods `loop.subprocess_shell()` and `loop.subprocess_exec()`.

## Base Transport

`BaseTransport.close()`

Close the transport.

If the transport has a buffer for outgoing data, buffered data will be flushed asynchronously. No more data will be received. After all buffered data is flushed, the protocol's `protocol.connection_lost()` method will be called with `None` as its argument. The transport should not be used once it is closed.

`BaseTransport.is_closing()`

Return `True` if the transport is closing or is closed.

`BaseTransport.get_extra_info(name, default=None)`

Return information about the transport or underlying resources it uses.

*name* is a string representing the piece of transport-specific information to get.

*default* is the value to return if the information is not available, or if the transport does not support querying it with the given third-party event loop implementation or on the current platform.

For example, the following code attempts to get the underlying socket object of the transport:

```
sock = transport.get_extra_info('socket')
if sock is not None:
```

```
print(sock.getsockopt(...))
```

Categories of information that can be queried on some transports:

- socket:
  - 'peername': the remote address to which the socket is connected, result of `socket.socket.getpeername()` (None on error)
  - 'socket': `socket.socket` instance
  - 'sockname': the socket's own address, result of `socket.socket.getsockname()`
- SSL socket:
  - 'compression': the compression algorithm being used as a string, or None if the connection isn't compressed; result of `ssl.SSLSocket.compression()`
  - 'cipher': a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used; result of `ssl.SSLSocket.cipher()`
  - 'peercert': peer certificate; result of `ssl.SSLSocket.getpeercert()`
  - 'sslcontext': `ssl.SSLContext` instance
  - 'ssl\_object': `ssl.SSLObject` or `ssl.SSLSocket` instance
- pipe:
  - 'pipe': pipe object
- subprocess:
  - 'subprocess': `subprocess.Popen` instance

`BaseTransport.set_protocol(protocol)`

Set a new protocol.

Switching protocol should only be done when both protocols are documented to support the switch.

`BaseTransport.get_protocol()`

Return the current protocol.

## Read-only Transports

`ReadTransport.is_reading()`

Return `True` if the transport is receiving new data.

*New in version 3.7.*

`ReadTransport.pause_reading()`

Pause the receiving end of the transport. No data will be passed to the protocol's `protocol.data_received()` method until `resume_reading()` is called.

*Changed in version 3.7:* The method is idempotent, i.e. it can be called when the transport is already paused or closed.

`ReadTransport.resume_reading()`

Resume the receiving end. The protocol's `protocol.data_received()` method will be called once again if some data is available for reading.

*Changed in version 3.7:* The method is idempotent, i.e. it can be called when the transport is already reading.

## Write-only Transports

`WriteTransport.abort()`

Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's `protocol.connection_lost()` method will eventually be called with `None` as its argument.

`WriteTransport.can_write_eof()`

Return `True` if the transport supports `write_eof()`, `False` if not.

`WriteTransport.get_write_buffer_size()`

Return the current size of the output buffer used by the transport.

`WriteTransport.get_write_buffer_limits()`

Get the *high* and *low* watermarks for write flow control. Return a tuple `(low, high)` where *low* and *high* are positive number of bytes.

Use `set_write_buffer_limits()` to set the limits.

*New in version 3.4.2.*

`WriteTransport.set_write_buffer_limits(high=None, low=None)`

Set the *high* and *low* watermarks for write flow control.

These two values (measured in number of bytes) control when the protocol's `protocol.pause_writing()` and `protocol.resume_writing()` methods are called. If specified, the low watermark must be less than or equal to the high watermark. Neither *high* nor *low* can be negative.

`pause_writing()` is called when the buffer size becomes greater than or equal to the *high* value. If writing has been paused, `resume_writing()` is called when the buffer size becomes less than or equal to the *low* value.

The defaults are implementation-specific. If only the high watermark is given, the low watermark defaults to an implementation-specific value less than or equal to the high watermark. Setting *high* to zero forces *low* to zero as well, and causes `pause_writing()` to be called whenever the buffer becomes non-empty. Setting *low* to zero causes `resume_writing()` to be called only once the buffer is empty. Use of zero for either limit is generally sub-optimal as it reduces opportunities for doing I/O and computation concurrently.

Use `get_write_buffer_limits()` to get the limits.

`WriteTransport.write(data)`

Write some *data* bytes to the transport.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

`WriteTransport.writelines(list_of_data)`

Write a list (or any iterable) of data bytes to the transport. This is functionally equivalent to calling `write()` on each element yielded by the iterable, but may be implemented more efficiently.

`WriteTransport.write_eof()`

Close the write end of the transport after flushing all buffered data. Data may still be received.

This method can raise `NotImplementedError` if the transport (e.g. SSL) doesn't support half-closed connections.

## Datagram Transports

`DatagramTransport.sendto(data, addr=None)`

Send the *data* bytes to the remote peer given by *addr* (a transport-dependent target address). If *addr* is `None`, the data is sent to the target address given on transport creation.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

`DatagramTransport.abort()`

Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's `protocol.connection_lost()` method will eventually be called with `None` as its argument.

## Subprocess Transports

## `SubprocessTransport.get_pid()`

Return the subprocess process id as an integer.

## `SubprocessTransport.get_pipe_transport(fd)`

Return the transport for the communication pipe corresponding to the integer file descriptor *fd*:

- 0: readable streaming transport of the standard input (*stdin*), or **None** if the subprocess was not created with `stdin=PIPE`
- 1: writable streaming transport of the standard output (*stdout*), or **None** if the subprocess was not created with `stdout=PIPE`
- 2: writable streaming transport of the standard error (*stderr*), or **None** if the subprocess was not created with `stderr=PIPE`
- other *fd*: **None**

## `SubprocessTransport.get_returncode()`

Return the subprocess return code as an integer or **None** if it hasn't returned, which is similar to the `subprocess.Popen.returncode` attribute.

## `SubprocessTransport.kill()`

Kill the subprocess.

On POSIX systems, the function sends SIGKILL to the subprocess. On Windows, this method is an alias for `terminate()`.

See also `subprocess.Popen.kill()`.

## `SubprocessTransport.send_signal(signal)`

Send the *signal* number to the subprocess, as in `subprocess.Popen.send_signal()`.

## `SubprocessTransport.terminate()`

Stop the subprocess.

On POSIX systems, this method sends SIGTERM to the subprocess. On Windows, the Windows API function `TerminateProcess()` is called to stop the subprocess.

See also `subprocess.Popen.terminate()`.

`SubprocessTransport.close()`

Kill the subprocess by calling the `kill()` method.

If the subprocess hasn't returned yet, and close transports of *stdin*, *stdout*, and *stderr* pipes.

## Protocols

**Source code:** [Lib/asyncio/protocols.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/protocols.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/protocols.py]

---

asyncio provides a set of abstract base classes that should be used to implement network protocols. Those classes are meant to be used together with [transports](#).

Subclasses of abstract base protocol classes may implement some or all methods. All these methods are callbacks: they are called by transports on certain events, for example when some data is received. A base protocol method should be called by the corresponding transport.

### Base Protocols

```
class asyncio.BaseProtocol
```

Base protocol with methods that all protocols share.

```
class asyncio.Protocol(BaseProtocol)
```

The base class for implementing streaming protocols (TCP, Unix sockets, etc).

`class asyncio.BufferedProtocol(BaseProtocol)`

A base class for implementing streaming protocols with manual control of the receive buffer.

`class asyncio.DatagramProtocol(BaseProtocol)`

The base class for implementing datagram (UDP) protocols.

`class asyncio.SubprocessProtocol(BaseProtocol)`

The base class for implementing protocols communicating with child processes (unidirectional pipes).

## Base Protocol

All asyncio protocols can implement Base Protocol callbacks.

### Connection Callbacks

Connection callbacks are called on all protocols, exactly once per a successful connection. All other protocol callbacks can only be called between those two methods.

`BaseProtocol.connection_made(transport)`

Called when a connection is made.

The *transport* argument is the transport representing the connection. The protocol is responsible for storing the reference to its transport.

`BaseProtocol.connection_lost(exc)`

Called when the connection is lost or closed.

The argument is either an exception object or **None**. The latter means a regular EOF is received, or the connection was aborted or closed by this side of the connection.

## Flow Control Callbacks

Flow control callbacks can be called by transports to pause or resume writing performed by the protocol.

See the documentation of the `set_write_buffer_limits()` method for more details.

`BaseProtocol.pause_writing()`

Called when the transport's buffer goes over the high watermark.

`BaseProtocol.resume_writing()`

Called when the transport's buffer drains below the low watermark.

If the buffer size equals the high watermark, `pause_writing()` is not called: the buffer size must go strictly over.

Conversely, `resume_writing()` is called when the buffer size is equal or lower than the low watermark. These end conditions are important to ensure that things go as expected when either mark is zero.

## Streaming Protocols

Event methods, such as `loop.create_server()`, `loop.create_unix_server()`, `loop.create_connection()`, `loop.create_unix_connection()`, `loop.connect_accepted_socket()`, `loop.connect_read_pipe()`, and `loop.connect_write_pipe()` accept factories that return streaming protocols.

`Protocol.data_received(data)`

Called when some data is received. *data* is a non-empty bytes object containing the incoming data.

Whether the data is buffered, chunked or reassembled depends on the transport. In general, you shouldn't rely on specific semantics and instead make your parsing generic and flexible. However, data is always received in the correct order.

The method can be called an arbitrary number of times while a connection is open.

However, `protocol.eof_received()` is called at most once. Once `eof_received()` is called, `data_received()` is not called anymore.

### `Protocol.eof_received()`

Called when the other end signals it won't send any more data (for example by calling `transport.write_eof()`, if the other end also uses asyncio).

This method may return a false value (including `None`), in which case the transport will close itself. Conversely, if this method returns a true value, the protocol used determines whether to close the transport. Since the default implementation returns `None`, it implicitly closes the connection.

Some transports, including SSL, don't support half-closed connections, in which case returning true from this method will result in the connection being closed.

State machine:

```
start -> connection_made
      [-> data_received]*
      [-> eof_received]?
-> connection_lost -> end
```

## Buffered Streaming Protocols

*New in version 3.7.*

Buffered Protocols can be used with any event loop method that supports [Streaming Protocols](#).

`BufferedProtocol` implementations allow explicit manual allocation and control of the receive buffer. Event loops can then use the buffer provided by the protocol to avoid unnecessary data copies. This can result in noticeable performance improvement for protocols that receive big amounts of data. Sophisticated protocol implementations can significantly reduce the number of buffer allocations.

The following callbacks are called on [BufferedProtocol](#) instances:

`BufferedProtocol.get_buffer(sizehint)`

Called to allocate a new receive buffer.

*sizehint* is the recommended minimum size for the returned buffer. It is acceptable to return smaller or larger buffers than what *sizehint* suggests. When set to -1, the buffer size can be arbitrary. It is an error to return a buffer with a zero size.

`get_buffer()` must return an object implementing the [buffer protocol](#).

`BufferedProtocol.buffer_updated(nbytes)`

Called when the buffer was updated with the received data.

*nbytes* is the total number of bytes that were written to the buffer.

`BufferedProtocol.eof_received()`

See the documentation of the [protocol.eof\\_received\(\)](#) method.

[get\\_buffer\(\)](#) can be called an arbitrary number of times during a connection. However, [protocol.eof\\_received\(\)](#) is called at most once and, if called, [get\\_buffer\(\)](#) and [buffer\\_updated\(\)](#) won't be called after it.

State machine:

```
start -> connection_made
    [-> get_buffer
        [-> buffer_updated]?
    ]*
    [-> eof_received]?
-> connection_lost -> end
```

## Datagram Protocols

Datagram Protocol instances should be constructed by protocol factories passed to the `loop.create_datagram_endpoint()` method.

`DatagramProtocol.datagram_received(data, addr)`

Called when a datagram is received. *data* is a bytes object containing the incoming data. *addr* is the address of the peer sending the data; the exact format depends on the transport.

`DatagramProtocol.error_received(exc)`

Called when a previous send or receive operation raises an `OSError`. *exc* is the `OSError` instance.

This method is called in rare conditions, when the transport (e.g. UDP) detects that a datagram could not be delivered to its recipient. In many conditions though, undeliverable datagrams will be silently dropped.

### Note

On BSD systems (macOS, FreeBSD, etc.) flow control is not supported for datagram protocols, because there is no reliable way to detect send failures caused by writing too many packets.

The socket always appears ‘ready’ and excess packets are dropped. An `OSError` with `errno` set to `errno.ENOBUFS` may or may not be raised; if it is raised, it will be reported to `DatagramProtocol.error_received()` but otherwise

ignored.

## Subprocess Protocols

Subprocess Protocol instances should be constructed by protocol factories passed to the `loop.subprocess_exec()` and `loop.subprocess_shell()` methods.

`SubprocessProtocol.pipe_data_received(fd, data)`

Called when the child process writes data into its stdout or stderr pipe.

*fd* is the integer file descriptor of the pipe.

*data* is a non-empty bytes object containing the received data.

`SubprocessProtocol.pipe_connection_lost(fd, exc)`

Called when one of the pipes communicating with the child process is closed.

*fd* is the integer file descriptor that was closed.

`SubprocessProtocol.process_exited()`

Called when the child process has exited.

## Examples

### TCP Echo Server

Create a TCP echo server using the `loop.create_server()` method, send back received data, and close the connection:

```
import asyncio
```

```
class EchoServerProtocol(asyncio.Protocol):
    def connection_made(self, transport):
        peername = transport.get_extra_info('peername')
```

```

        print('Connection from {}'.format(peername))
        self.transport = transport

    def data_received(self, data):
        message = data.decode()
        print('Data received: {!r}'.format(message))

        print('Send: {!r}'.format(message))
        self.transport.write(data)

        print('Close the client socket')
        self.transport.close()

async def main():
    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()

    server = await loop.create_server(
        lambda: EchoServerProtocol(),
        '127.0.0.1', 8888)

    async with server:
        await server.serve_forever()

asyncio.run(main())

```

## See also

The [TCP echo server using streams](#) example uses the high-level [`asyncio.start\_server\(\)`](#) function.

## TCP Echo Client

A TCP echo client using the [`loop.create\_connection\(\)`](#) method, sends data, and waits until the connection is closed:

```
import asyncio
```

```
class EchoClientProtocol(asyncio.Protocol):
    def __init__(self, message, on_con_lost):
        self.message = message
        self.on_con_lost = on_con_lost

    def connection_made(self, transport):
        transport.write(self.message.encode())
        print('Data sent: {!r}'.format(self.message))

    def data_received(self, data):
        print('Data received: {!r}'.format(data.decode()))

    def connection_lost(self, exc):
        print('The server closed the connection')
        self.on_con_lost.set_result(True)
```

```
async def main():
    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()

    on_con_lost = loop.create_future()
    message = 'Hello World!'

    transport, protocol = await loop.create_connection(
        lambda: EchoClientProtocol(message, on_con_lost),
        '127.0.0.1', 8888)

    # Wait until the protocol signals that the connection
    # is lost and close the transport.
    try:
        await on_con_lost
    finally:
        transport.close()
```

```
asyncio.run(main())
```

## See also

The [TCP echo client using streams](#) example uses the high-level [`asyncio.open\_connection\(\)`](#) function.

## UDP Echo Server

A UDP echo server, using the [`loop.create\_datagram\_endpoint\(\)`](#) method, sends back received data:

```
import asyncio

class EchoServerProtocol:
    def connection_made(self, transport):
        self.transport = transport

    def datagram_received(self, data, addr):
        message = data.decode()
        print('Received %r from %s' % (message, addr))
        print('Send %r to %s' % (message, addr))
        self.transport.sendto(data, addr)

async def main():
    print("Starting UDP server")

    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()

    # One protocol instance will be created to serve all
    # client requests.
```

```

transport, protocol = await loop.create_datagram_endpoint(
    lambda: EchoServerProtocol(),
    local_addr=('127.0.0.1', 9999))

try:
    await asyncio.sleep(3600) # Serve for 1 hour.
finally:
    transport.close()

```

```

asyncio.run(main())

```

## UDP Echo Client

A UDP echo client, using the [loop.create\\_datagram\\_endpoint\(\)](#) method, sends data and closes the transport when it receives the answer:

```

import asyncio

class EchoClientProtocol:
    def __init__(self, message, on_con_lost):
        self.message = message
        self.on_con_lost = on_con_lost
        self.transport = None

    def connection_made(self, transport):
        self.transport = transport
        print('Send:', self.message)
        self.transport.sendto(self.message.encode())

    def datagram_received(self, data, addr):
        print("Received:", data.decode())

        print("Close the socket")
        self.transport.close()

    def error_received(self, exc):

```

```

        print('Error received:', exc)

    def connection_lost(self, exc):
        print("Connection closed")
        self.on_con_lost.set_result(True)

async def main():
    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()

    on_con_lost = loop.create_future()
    message = "Hello World!"

    transport, protocol = await loop.create_datagram_endpoint(
        lambda: EchoClientProtocol(message, on_con_lost),
        remote_addr=('127.0.0.1', 9999))

    try:
        await on_con_lost
    finally:
        transport.close()

asyncio.run(main())

```

## Connecting Existing Sockets

Wait until a socket receives data using the [loop.create\\_connection\(\)](#) method with a protocol:

```

import asyncio
import socket

class MyProtocol(asyncio.Protocol):

    def __init__(self, on_con_lost):

```

```

        self.transport = None
        self.on_con_lost = on_con_lost

    def connection_made(self, transport):
        self.transport = transport

    def data_received(self, data):
        print("Received:", data.decode())

        # We are done: close the transport;
        # connection_lost() will be called automatically
        self.transport.close()

    def connection_lost(self, exc):
        # The socket has been closed
        self.on_con_lost.set_result(True)

async def main():
    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()
    on_con_lost = loop.create_future()

    # Create a pair of connected sockets
    rsock, wsock = socket.socketpair()

    # Register the socket to wait for data.
    transport, protocol = await loop.create_connection(
        lambda: MyProtocol(on_con_lost), sock=rsock)

    # Simulate the reception of data from the network.
    loop.call_soon(wsock.send, 'abc'.encode())

    try:
        await protocol.on_con_lost
    finally:
        transport.close()

```

```
wsock.close()

asyncio.run(main())
```

## See also

The [watch a file descriptor for read events](#) example uses the low-level `loop.add_reader()` method to register an FD.

The [register an open socket to wait for data using streams](#) example uses high-level streams created by the `open_connection()` function in a coroutine.

## loop.subprocess\_exec() and SubprocessProtocol

An example of a subprocess protocol used to get the output of a subprocess and to wait for the subprocess exit.

The subprocess is created by the `loop.subprocess_exec()` method:

```
import asyncio
import sys

class DateProtocol(asyncio.SubprocessProtocol):
    def __init__(self, exit_future):
        self.exit_future = exit_future
        self.output = bytearray()

    def pipe_data_received(self, fd, data):
        self.output.extend(data)

    def process_exited(self):
        self.exit_future.set_result(True)

async def get_date():
    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()
```

```
code = 'import datetime; print(datetime.datetime.now())'
exit_future = asyncio.Future(loop=loop)

# Create the subprocess controlled by DateProtocol;
# redirect the standard output into a pipe.
transport, protocol = await loop.subprocess_exec(
    lambda: DateProtocol(exit_future),
    sys.executable, '-c', code,
    stdin=None, stderr=None)

# Wait for the subprocess exit using the process_exit
# method of the protocol.
await exit_future

# Close the stdout pipe.
transport.close()

# Read the output which was collected by the
# pipe_data_received() method of the protocol.
data = bytes(protocol.output)
return data.decode('ascii').rstrip()

date = asyncio.run(get_date())
print(f"Current date: {date}")
```

See also the [same example](#) written using high-level APIs.

# Policies

An event loop policy is a global object used to get and set the current [event loop](#), as well as create new event loops. The default policy can be [replaced](#) with [built-in alternatives](#) to use different event loop implementations, or substituted by a [custom policy](#) that can override these behaviors.

The [policy object](#) gets and sets a separate event loop per *context*. This is per-thread by default, though custom policies could define *context* differently.

Custom event loop policies can control the behavior of [get\\_event\\_loop\(\)](#), [set\\_event\\_loop\(\)](#), and [new\\_event\\_loop\(\)](#).

Policy objects should implement the APIs defined in the [AbstractEventLoopPolicy](#) abstract base class.

## Getting and Setting the Policy

The following functions can be used to get and set the policy for the current process:

```
asyncio.get_event_loop_policy()
```

Return the current process-wide policy.

```
asyncio.set_event_loop_policy(policy)
```

Set the current process-wide policy to *policy*.

If *policy* is set to `None`, the default policy is restored.

## Policy Objects

The abstract event loop policy base class is defined as follows:

```
class asyncio.AbstractEventLoopPolicy
```

An abstract base class for asyncio policies.

```
get_event_loop()
```

Get the event loop for the current context.

Return an event loop object implementing the **AbstractEventLoop** interface.

This method should never return `None`.

*Changed in version 3.6.*

```
set_event_loop(loop)
```

Set the event loop for the current context to *loop*.

```
new_event_loop()
```

Create and return a new event loop object.

This method should never return `None`.

```
get_child_watcher()
```

Get a child process watcher object.

Return a watcher object implementing the **AbstractChildWatcher** interface.

This function is Unix specific.

```
set_child_watcher(watcher)
```

Set the current child process watcher to *watcher*.

This function is Unix specific.

asyncio ships with the following built-in policies:

```
class asyncio.DefaultEventLoopPolicy
```

The default `asyncio` policy. Uses `SelectorEventLoop` on Unix and `ProactorEventLoop` on Windows.

There is no need to install the default policy manually. `asyncio` is configured to use the default policy automatically.

*Changed in version 3.8:* On Windows, `ProactorEventLoop` is now used by default.

### Note

In Python versions 3.10.9, 3.11.1 and 3.12 the `get_event_loop()` method of the default `asyncio` policy emits a `DeprecationWarning` if there is no running event loop and no current loop is set. In some future Python release this will become an error.

`class asyncio.WindowsSelectorEventLoopPolicy`

An alternative event loop policy that uses the `SelectorEventLoop` event loop implementation.

*Availability:* Windows.

`class asyncio.WindowsProactorEventLoopPolicy`

An alternative event loop policy that uses the `ProactorEventLoop` event loop implementation.

*Availability:* Windows.

## Process Watchers

A process watcher allows customization of how an event loop monitors child processes on Unix. Specifically, the event loop needs to know when a child process has exited.

In `asyncio`, child processes are created with `create_subprocess_exec()` and `loop.subprocess_exec()` functions.

asyncio defines the `AbstractChildWatcher` abstract base class, which child watchers should implement, and has four different implementations: `ThreadedChildWatcher` (configured to be used by default), `MultiLoopChildWatcher`, `SafeChildWatcher`, and `FastChildWatcher`.

See also the [Subprocess and Threads](#) section.

The following two functions can be used to customize the child process watcher implementation used by the asyncio event loop:

`asyncio.get_child_watcher()`

Return the current child watcher for the current policy.

`asyncio.set_child_watcher(watcher)`

Set the current child watcher to *watcher* for the current policy. *watcher* must implement methods defined in the `AbstractChildWatcher` base class.

### Note

Third-party event loops implementations might not support custom child watchers. For such event loops, using `set_child_watcher()` might be prohibited or have no effect.

`class asyncio.AbstractChildWatcher`

`add_child_handler(pid, callback, *args)`

Register a new child handler.

Arrange for `callback(pid, returncode, *args)` to be called when a process with PID equal to *pid* terminates. Specifying another callback for the same process replaces the previous handler.

The *callback* callable must be thread-safe.

`remove_child_handler(pid)`

Removes the handler for process with PID equal to *pid*.

The function returns `True` if the handler was successfully removed, `False` if there was nothing to remove.

`attach_loop(loop)`

Attach the watcher to an event loop.

If the watcher was previously attached to an event loop, then it is first detached before attaching to the new loop.

Note: loop may be `None`.

`is_active()`

Return `True` if the watcher is ready to use.

Spawning a subprocess with *inactive* current child watcher raises `RuntimeError`.

*New in version 3.8.*

`close()`

Close the watcher.

This method has to be called to ensure that underlying resources are cleaned-up.

*class* `asyncio.ThreadedChildWatcher`

This implementation starts a new waiting thread for every subprocess spawn.

It works reliably even when the `asyncio` event loop is run in a non-main OS thread.

There is no noticeable overhead when handling a big number of children ( $O(1)$  each time a child terminates), but starting a thread per process requires extra memory.

This watcher is used by default.

*New in version 3.8.*

`class asyncio.MultiLoopChildWatcher`

This implementation registers a **SIGCHLD** signal handler on instantiation. That can break third-party code that installs a custom handler for **SIGCHLD** signal.

The watcher avoids disrupting other code spawning processes by polling every process explicitly on a **SIGCHLD** signal.

There is no limitation for running subprocesses from different threads once the watcher is installed.

The solution is safe but it has a significant overhead when handling a big number of processes ( $O(n)$  each time a **SIGCHLD** is received).

*New in version 3.8.*

`class asyncio.SafeChildWatcher`

This implementation uses active event loop from the main thread to handle **SIGCHLD** signal. If the main thread has no running event loop another thread cannot spawn a subprocess (**RuntimeError** is raised).

The watcher avoids disrupting other code spawning processes by polling every process explicitly on a **SIGCHLD** signal.

This solution is as safe as **MultiLoopChildWatcher** and has the same  $O(N)$  complexity but requires a running event loop in the main thread to work.

`class asyncio.FastChildWatcher`

This implementation reaps every terminated processes by calling `os.waitpid(-1)` directly, possibly breaking other code spawning processes and waiting for their termination.

There is no noticeable overhead when handling a big number

of children ( $O(1)$  each time a child terminates).

This solution requires a running event loop in the main thread to work, as [SafeChildWatcher](#).

*class* `asyncio.PidfdChildWatcher`

This implementation polls process file descriptors (pidfds) to await child process termination. In some respects, [PidfdChildWatcher](#) is a “Goldilocks” child watcher implementation. It doesn’t require signals or threads, doesn’t interfere with any processes launched outside the event loop, and scales linearly with the number of subprocesses launched by the event loop. The main disadvantage is that pidfds are specific to Linux, and only work on recent (5.3+) kernels.

*New in version 3.9.*

## Custom Policies

To implement a new event loop policy, it is recommended to subclass [DefaultEventLoopPolicy](#) and override the methods for which custom behavior is wanted, e.g.:

```
class MyEventLoopPolicy(asyncio.DefaultEventLoopPolicy):

    def get_event_loop(self):
        """Get the event loop.

        This may be None or an instance of EventLoop.
        """
        loop = super().get_event_loop()
        # Do something with loop ...
        return loop

asyncio.set_event_loop_policy(MyEventLoopPolicy())
```

# Platform Support

The `asyncio` module is designed to be portable, but some platforms have subtle differences and limitations due to the platforms' underlying architecture and capabilities.

## All Platforms

- `loop.add_reader()` and `loop.add_writer()` cannot be used to monitor file I/O.

## Windows

**Source code:** [Lib/asyncio/proactor\\_events.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/proactor_events.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/proactor\_events.py], [Lib/asyncio/windows\\_events.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/windows_events.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/windows\_events.py], [Lib/asyncio/windows\\_utils.py](https://github.com/python/cpython/tree/3.11/Lib/asyncio/windows_utils.py) [https://github.com/python/cpython/tree/3.11/Lib/asyncio/windows\_utils.py]

---

*Changed in version 3.8:* On Windows, `ProactorEventLoop` is now the default event loop.

All event loops on Windows do not support the following methods:

- `loop.create_unix_connection()` and `loop.create_unix_server()` are not supported. The `socket.AF_UNIX` socket family is specific to Unix.
- `loop.add_signal_handler()` and `loop.remove_signal_handler()` are not supported.

`SelectorEventLoop` has the following limitations:

- `SelectSelector` is used to wait on socket events: it supports sockets and is limited to 512 sockets.
- `loop.add_reader()` and `loop.add_writer()` only

accept socket handles (e.g. pipe file descriptors are not supported).

- Pipes are not supported, so the `loop.connect_read_pipe()` and `loop.connect_write_pipe()` methods are not implemented.
- `Subprocesses` are not supported, i.e. `loop.subprocess_exec()` and `loop.subprocess_shell()` methods are not implemented.

`ProactorEventLoop` has the following limitations:

- The `loop.add_reader()` and `loop.add_writer()` methods are not supported.

The resolution of the monotonic clock on Windows is usually around 15.6 milliseconds. The best resolution is 0.5 milliseconds. The resolution depends on the hardware (availability of `HPET` [[https://en.wikipedia.org/wiki/High\\_Precision\\_Event\\_Timer](https://en.wikipedia.org/wiki/High_Precision_Event_Timer)]) and on the Windows configuration.

## Subprocess Support on Windows

On Windows, the default event loop `ProactorEventLoop` supports subprocesses, whereas `SelectorEventLoop` does not.

The `policy.set_child_watcher()` function is also not supported, as `ProactorEventLoop` has a different mechanism to watch child processes.

## macOS

Modern macOS versions are fully supported.

**macOS <= 10.8**

On macOS 10.6, 10.7 and 10.8, the default event loop uses `selectors.KqueueSelector`, which does not support character

devices on these versions. The `SelectorEventLoop` can be manually configured to use `SelectSelector` or `PollSelector` to support character devices on these older versions of macOS.  
Example:

```
import asyncio
import selectors

selector = selectors.SelectSelector()
loop = asyncio.SelectorEventLoop(selector)
asyncio.set_event_loop(loop)
```

# Extending

The main direction for `asyncio` extending is writing custom *event loop* classes. Asyncio has helpers that could be used to simplify this task.

## Note

Third-parties should reuse existing asyncio code with caution, a new Python version is free to break backward compatibility in *internal* part of API.

## Writing a Custom Event Loop

`asyncio.AbstractEventLoop` declares very many methods. Implementing all them from scratch is a tedious job.

A loop can get many common methods implementation for free by inheriting from `asyncio.BaseEventLoop`.

In turn, the successor should implement a bunch of *private* methods declared but not implemented in `asyncio.BaseEventLoop`.

For example, `loop.create_connection()` checks arguments, resolves DNS addresses, and calls `loop._make_socket_transport()` that should be implemented by inherited class. The `_make_socket_transport()` method is not documented and is considered as an *internal* API.

## Future and Task private constructors

`asyncio.Future` and `asyncio.Task` should be never created directly, please use corresponding `loop.create_future()` and `loop.create_task()`, or `asyncio.create_task()` factories instead.

However, third-party *event loops* may *reuse* built-in future and task implementations for the sake of getting a complex and highly optimized code for free.

For this purpose the following, *private* constructors are listed:

`Future._init_(*, loop=None)`

Create a built-in future instance.

*loop* is an optional event loop instance.

`Task._init_(coro, *, loop=None, name=None, context=None)`

Create a built-in task instance.

*loop* is an optional event loop instance. The rest of arguments are described in `loop.create_task()` description.

*Changed in version 3.11: context argument is added.*

## Task lifetime support

A third party task implementation should call the following functions to keep a task visible by `asyncio.get_tasks()` and `asyncio.current_task()`:

`asyncio.register_task(task)`

Register a new *task* as managed by *asyncio*.

Call the function from a task constructor.

`asyncio.unregister_task(task)`

Unregister a *task* from *asyncio* internal structures.

The function should be called when a task is about to finish.

`asyncio.enter_task(loop, task)`

Switch the current task to the *task* argument.

Call the function just before executing a portion of embedded *coroutine* (`coroutine.send()` or `coroutine.throw()`).

`asyncio._leave_task(loop, task)`

Switch the current task back from *task* to `None`.

Call the function just after `coroutine.send()` or `coroutine.throw()` execution.

# High-level API Index

This page lists all high-level `async/await` enabled `asyncio` APIs.

## Tasks

Utilities to run `asyncio` programs, create `Tasks`, and await on multiple things with timeouts.

`Create` event loop, run a coroutine, close the loop.

`Acontext` manager that simplifies multiple `async` function calls.

`Task` object.

`Acontextup` manager that holds a group of tasks. Provides a convenient and reliable way to wait for all tasks in the group to finish.

`Start an asyncio() Task`, then returns it.

`Return the current` Task.

`Return all tasks` that are not yet finished for an event loop.

`Sleep for a number` of seconds.

`Schedule and wait` for things concurrently.

`Run with a timeout()`

`Shield from cancellation`.

`Monitor for completion`.

`Run with a` timeout. Useful in cases when `wait_for` is not suitable.

`Asynchronously` run a function in a separate OS thread.

`Schedule a coroutine from another` OS thread.

`Monitor for completion with` a `for` loop.

## Examples

- Using `asyncio.gather()` to run things in parallel.
- Using `asyncio.wait_for()` to enforce a timeout.
- Cancellation.

- [Using `asyncio.sleep\(\)`](#).
- See also the main [Tasks documentation page](#).

## Queues

Queues should be used to distribute work amongst multiple `asyncio` Tasks, implement connection pools, and pub/sub patterns.

[A FIFO queue](#).

[A priority queue](#).

[A LIFO queue](#).

### Examples

- [Using `asyncio.Queue` to distribute workload between several Tasks](#).
- See also the [Queues documentation page](#).

## Subprocesses

Utilities to spawn subprocesses and run shell commands.

[Create a subprocess](#) `subprocess_exec()`

[Run a shell command](#) `subprocess_shell()`

### Examples

- [Executing a shell command](#).
- See also the [subprocess APIs](#) documentation.

## Streams

High-level APIs to work with network IO.

[Establish a TCP connection](#) `open_connection()`

[Establish a Unix socket connection](#) `open_unix_socket()`

[Start a TCP server](#) `start_server()`

Start a Unix socket server. [UnixSocketServer\(\)](#)

---

High-level [async](#)/await object to receive network data.

---

High-level [async](#)/await object to send network data.

---

## Examples

- [Example TCP client](#).
- See also the [streams APIs](#) documentation.

# Synchronization

Threading-like synchronization primitives that can be used in Tasks.

[A](#) mutex lock.

---

[A](#) event object.

---

[A](#) condition object.

---

[A](#) semaphore.

---

[A](#) bounded semaphore.

---

[A](#) barrier object.

---

## Examples

- [Using `asyncio.Event`](#).
- [Using `asyncio.Barrier`](#).
- See also the documentation of `asyncio` [synchronization primitives](#).

# Exceptions

[Raised when a Task is cancelled](#). See also [Task.cancel\(\)](#).

---

[Raised when a Barrier is broken](#). See also [Barrier.wait\(\)](#).

---

## Examples

- [Handling `CancelledError` to run code on cancellation request](#).
- See also the full list of [asyncio-specific exceptions](#).

# Low-level API Index

This page lists all low-level asyncio APIs.

## Obtaining the Event Loop

The preferred function to get the running event loop.

Get an event loop instance (running or current via the current policy).

Set the event loop as current via the current policy.

Create a new event loop.

### Examples

- Using `asyncio.get_running_loop()`.

## Event Loop Methods

See also the main documentation section about the [Event Loop Methods](#).

### Lifecycle

Run a `Future/Task/awaitable` until complete.

Run the event loop forever.

Stop the event loop.

Close the event loop.

Return `True` if the event loop is running.

Return `True` if the event loop is closed.

Close asynchronous generators.

## Debugging

Enable or disable the debug mode.

Get the current debug mode.

---

## Scheduling Callbacks

Invoke a callback soon.

A thread-safe variant of `relatimefn()`.

Invoke a callback after the given time.

Invoke a callback at the given time.

---

## Thread/Process Pool

Run a CPU-bound or other blocking function in a `concurrent.futures` executor.

Set the default executor for `concurrent.futures.run_in_executor()`.

---

## Tasks and Futures

Create a `Future` object.

Schedule a coroutine as a `Task`.

Set a factory used by `create_task()` to create `Tasks`.

Get the factory `task_factory` used to create `Tasks`.

---

## DNS

Asynchronous version of `socket.getaddrinfo()`.

Asynchronous version of `socket.getnameinfo()`.

---

## Networking and IPC

Open a TCP connection.

Create a TCP server.

Open a Unix socket connection.

---

Create a Unix socket server: `unix_server()`  
Wrap a socket into a `accepted_socket()` pair.  
Open a datagram (UDP) connection: `connection_endpoint()`  
Send a file over a transport.  
Upgrade an existing connection to TLS.  
Wrap a read end of a pipe into a `pipe()` transport, (protocol)  
pair.  
Wrap a write end of a pipe into a `pipe()` transport, (protocol)  
pair.

## Sockets

Receive data from the socket.  
Receive data from the socket into a buffer.  
Receive a datagram from the socket.  
Receive a datagram from the socket into a buffer.  
Send data to the socket: `sendall()`  
Send a datagram via the socket to the given address.  
Connect the socket: `connect()`  
Accept a socket connection: `accept()`  
Send a file over the socket: `sendfile()`  
Start watching a file descriptor for read availability.  
Stop watching a file descriptor for read availability.  
Start watching a file descriptor for write availability.  
Stop watching a file descriptor for write availability.

## Unix Signals

Add a handler for a signal: `signal()`  
Remove a handler for a signal: `unset_signal_handler()`

## Subprocesses

Spawn a subprocess: `exec()`  
Spawn a subprocess from a shell command.

## Error Handling

---

Call the exception handler. `handler()`

---

Set a new exception handler. `handler()`

---

Get the current exception handler. `handler()`

---

The default exception handler implementation.

---

## Examples

- Using `asyncio.new_event_loop()` and `loop.run_forever()`.
- Using `loop.call_later()`.
- Using `loop.create_connection()` to implement an [echo-client](#).
- Using `loop.create_connection()` to [connect a socket](#).
- Using `add_reader()` to watch an FD for read events.
- Using `loop.add_signal_handler()`.
- Using `loop.subprocess_exec()`.

## Transports

All transports implement the following methods:

---

Close the transport. `close()`

---

Return `True` if the transport is closing or is closed.

---

Request for information about the transport.

---

Set a new protocol. `protocol()`

---

Return the current protocol. `protocol()`

---

Transports that can receive data (TCP and Unix connections, pipes, etc). Returned from methods like `loop.create_connection()`, `loop.create_unix_connection()`, `loop.connect_read_pipe()`, etc:

## Read Transports

---

Return `True` if the transport is receiving.

---

Pause receiving. `pause_reading()`

---

Resume receiving. `resume_reading()`

---

Transports that can Send data (TCP and Unix connections, pipes, etc). Returned from methods like `loop.create_connection()`, `loop.create_unix_connection()`, `loop.connect_write_pipe()`, etc:

## Write Transports

Writes data to the transport.

---

Writes buffers to the transport.

---

Return `True` if the transport supports sending EOF.

---

Close and send EOF after flushing buffered data.

---

Close the transport immediately.

---

Return the current size of the output buffer.

---

Return high and low water marks for write flow control.

---

Set new high and low water marks for write flow control.

---

Transports returned by `loop.create_datagram_endpoint()`:

## Datagram Transports

Send data to the remote peer.

---

Close the transport immediately.

---

Low-level transport abstraction over subprocesses. Returned by `loop.subprocess_exec()` and `loop.subprocess_shell()`:

## Subprocess Transports

Return the subprocess process id.

---

Return the transport for the requested communication pipe (`stdin`, `stdout`, or `stderr`).

---

Return the subprocess return code.

---

Kill the subprocess.

---

Send a signal to the subprocess.

---

Stop the subprocess.

---

Kill the subprocess and close all pipes.

---

# Protocols

Protocol classes can implement the following **callback methods**:

Called when a connection is made.  
`cb.connect()`

---

Called when the connection is lost or closed.  
`cb.disconnect()`

---

Called when the transport's buffer goes over the high water mark.  
`cb.pushBytes()`

---

Called when the transport's buffer drains below the low water mark.  
`cb.popBytes()`

---

## Streaming Protocols (TCP, Unix Sockets, Pipes)

Called when some data is received.  
`cb.receive()`

---

Called when an EOF is received.  
`cb.receive_eof()`

---

## Buffered Streaming Protocols

Called to allocate a new receive buffer.  
`cb.getReceiveBuffer()`

---

Called when the buffer was updated with the received data.  
`cb.updateBuffer()`

---

Called when an EOF is received.  
`cb.receive_eof()`

---

## Datagram Protocols

Called when a datagram is received.  
`cb.receiveDatagram()`

---

Called when a previous send or receive operation raises an `OSError`.  
`cb.resume()`

---

## Subprocess Protocols

Called when the child process writes data into its `stdout` or `stderr` pipe.  
`cb.writeData()`

---

Called when one of the pipes communicating with the child process is closed.  
`cb.closePipe()`

---

Called when the child process has exited.  
`cb.closeProcess()`

---

# Event Loop Policies

Policies is a low-level mechanism to alter the behavior of functions like `asyncio.get_event_loop()`. See also the main [policies section](#) for more details.

## Accessing Policies

[Return the current process-wide policy.](#) `get_event_loop_policy()`

---

[Set a new process-wide policy.](#) `policy()`

---

[Base class for policy objects.](#) `Policy`

---

# Developing with asyncio

Asynchronous programming is different from classic “sequential” programming.

This page lists common mistakes and traps and explains how to avoid them.

## Debug Mode

By default asyncio runs in production mode. In order to ease the development asyncio has a *debug mode*.

There are several ways to enable asyncio debug mode:

- Setting the `PYTHONASYNCIODEBUG` environment variable to 1.
- Using the [Python Development Mode](#).
- Passing `debug=True` to `asyncio.run()`.
- Calling `loop.set_debug()`.

In addition to enabling the debug mode, consider also:

- setting the log level of the [asyncio logger](#) to `logging.DEBUG`, for example the following snippet of code can be run at startup of the application:

```
logging.basicConfig(level=logging.DEBUG)
```

- configuring the `warnings` module to display [ResourceWarning](#) warnings. One way of doing that is by using the `-W` default command line option.

When the debug mode is enabled:

- asyncio checks for [coroutines that were not awaited](#) and logs them; this mitigates the “forgotten await” pitfall.

- Many non-threadsafe asyncio APIs (such as `loop.call_soon()` and `loop.call_at()` methods) raise an exception if they are called from a wrong thread.
- The execution time of the I/O selector is logged if it takes too long to perform an I/O operation.
- Callbacks taking longer than 100 milliseconds are logged. The `loop.slow_callback_duration` attribute can be used to set the minimum execution duration in seconds that is considered “slow”.

## Concurrency and Multithreading

An event loop runs in a thread (typically the main thread) and executes all callbacks and Tasks in its thread. While a Task is running in the event loop, no other Tasks can run in the same thread. When a Task executes an `await` expression, the running Task gets suspended, and the event loop executes the next Task.

To schedule a `callback` from another OS thread, the `loop.call_soon_threadsafe()` method should be used. Example:

```
loop.call_soon_threadsafe(callback, *args)
```

Almost all asyncio objects are not thread safe, which is typically not a problem unless there is code that works with them from outside of a Task or a callback. If there’s a need for such code to call a low-level asyncio API, the `loop.call_soon_threadsafe()` method should be used, e.g.:

```
loop.call_soon_threadsafe(fut.cancel)
```

To schedule a coroutine object from a different OS thread, the `run_coroutine_threadsafe()` function should be used. It returns a `concurrent.futures.Future` to access the result:

```
async def coro_func():
    return await asyncio.sleep(1, 42)

# Later in another OS thread:
```

```
future = asyncio.run_coroutine_threadsafe(coro_func(), loop)
# Wait for the result:
result = future.result()
```

To handle signals and to execute subprocesses, the event loop must be run in the main thread.

The `loop.run_in_executor()` method can be used with a `concurrent.futures.ThreadPoolExecutor` to execute blocking code in a different OS thread without blocking the OS thread that the event loop runs in.

There is currently no way to schedule coroutines or callbacks directly from a different process (such as one started with `multiprocessing`). The [Event Loop Methods](#) section lists APIs that can read from pipes and watch file descriptors without blocking the event loop. In addition, `asyncio`'s [Subprocess](#) APIs provide a way to start a process and communicate with it from the event loop. Lastly, the aforementioned `loop.run_in_executor()` method can also be used with a `concurrent.futures.ProcessPoolExecutor` to execute code in a different process.

## Running Blocking Code

Blocking (CPU-bound) code should not be called directly. For example, if a function performs a CPU-intensive calculation for 1 second, all concurrent `asyncio` Tasks and IO operations would be delayed by 1 second.

An executor can be used to run a task in a different thread or even in a different process to avoid blocking the OS thread with the event loop. See the `loop.run_in_executor()` method for more details.

## Logging

`asyncio` uses the `logging` module and all logging is performed via

the "asyncio" logger.

The default log level is `logging.INFO`, which can be easily adjusted:

```
logging.getLogger("asyncio").setLevel(logging.WARNING)
```

Network logging can block the event loop. It is recommended to use a separate thread for handling logs or use non-blocking IO. For example, see [Dealing with handlers that block](#).

## Detect never-awaited coroutines

When a coroutine function is called, but not awaited (e.g. `coro()` instead of `await coro()`) or the coroutine is not scheduled with `asyncio.create_task()`, asyncio will emit a `RuntimeWarning`:

```
import asyncio

async def test():
    print("never scheduled")

async def main():
    test()

asyncio.run(main())
```

Output:

```
test.py:7: RuntimeWarning: coroutine 'test' was never awaited
    test()
```

Output in debug mode:

```
test.py:7: RuntimeWarning: coroutine 'test' was never awaited
Coroutine created at (most recent call last)
  File "../t.py", line 9, in <module>
    asyncio.run(main(), debug=True)
```

```
< .. >
```

```
File "../t.py", line 7, in main
    test()
test()
```

The usual fix is to either await the coroutine or call the `asyncio.create_task()` function:

```
async def main():
    await test()
```

## Detect never-retrieved exceptions

If a `Future.set_exception()` is called but the Future object is never awaited on, the exception would never be propagated to the user code. In this case, asyncio would emit a log message when the Future object is garbage collected.

Example of an unhandled exception:

```
import asyncio

async def bug():
    raise Exception("not consumed")

async def main():
    asyncio.create_task(bug())

asyncio.run(main())
```

Output:

```
Task exception was never retrieved
future: <Task finished coro=<bug() done, defined at test.py:4>
      exception=Exception('not consumed')>
```

```
Traceback (most recent call last):
  File "test.py", line 4, in bug
```

```
        raise Exception("not consumed")
Exception: not consumed
```

[Enable the debug mode](#) to get the traceback where the task was created:

```
asyncio.run(main(), debug=True)
```

Output in debug mode:

```
Task exception was never retrieved
future: <Task finished coro=<bug() done, defined at test
      exception=Exception('not consumed') created at asynco

source_traceback: Object created at (most recent call last)
  File "../t.py", line 9, in <module>
    asyncio.run(main(), debug=True)

< .. >
```

```
Traceback (most recent call last):
  File "../t.py", line 4, in bug
    raise Exception("not consumed")
Exception: not consumed
```

# socket — Low-level networking interface

**Source code:** [Lib/socket.py](https://github.com/python/cpython/tree/3.11/Lib/socket.py) [https://github.com/python/cpython/tree/3.11/Lib/socket.py]

---

This module provides access to the BSD *socket* interface. It is available on all modern Unix systems, Windows, MacOS, and probably additional platforms.

## Note

Some behavior may be platform dependent, since calls are made to the operating system socket APIs.

**Availability:** not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See [WebAssembly platforms](#) for more information.

The Python interface is a straightforward transliteration of the Unix system call and library interface for sockets to Python's object-oriented style: the **socket()** function returns a *socket object* whose methods implement the various socket system calls. Parameter types are somewhat higher-level than in the C interface: as with **read()** and **write()** operations on Python files, buffer allocation on receive operations is automatic, and buffer length is implicit on send operations.

## See also

### Module [socketserver](#)

Classes that simplify writing network servers.

## Module `ssl`

A TLS/SSL wrapper for socket objects.

# Socket families

Depending on the system and the build options, various socket families are supported by this module.

The address format required by a particular socket object is automatically selected based on the address family specified when the socket object was created. Socket addresses are represented as follows:

- The address of an `AF_UNIX` socket bound to a file system node is represented as a string, using the file system encoding and the `'surrogateescape'` error handler (see [PEP 383](https://peps.python.org/pep-0383/) [https://peps.python.org/pep-0383/]). An address in Linux's abstract namespace is returned as a `bytes-like object` with an initial null byte; note that sockets in this namespace can communicate with normal file system sockets, so programs intended to run on Linux may need to deal with both types of address. A string or bytes-like object can be used for either type of address when passing it as an argument.

*Changed in version 3.3:* Previously, `AF_UNIX` socket paths were assumed to use UTF-8 encoding.

*Changed in version 3.5:* Writable `bytes-like object` is now accepted.

- A pair `(host, port)` is used for the `AF_INET` address family, where `host` is a string representing either a hostname in internet domain notation like `'daring.cwi.nl'` or an IPv4 address like `'100.50.200.5'`, and `port` is an integer.
  - For IPv4 addresses, two special forms are accepted instead of a host address: `''` represents `INADDR_ANY`, which is used to bind to all interfaces, and the string `'<broadcast>'` represents `INADDR_BROADCAST`. This behavior is not compatible with IPv6, therefore,

you may want to avoid these if you intend to support IPv6 with your Python programs.

- For **AF\_INET6** address family, a four-tuple (*host*, *port*, *flowinfo*, *scope\_id*) is used, where *flowinfo* and *scope\_id* represent the *sin6\_flowinfo* and *sin6\_scope\_id* members in **struct sockaddr\_in6** in C. For **socket** module methods, *flowinfo* and *scope\_id* can be omitted just for backward compatibility. Note, however, omission of *scope\_id* can cause problems in manipulating scoped IPv6 addresses.

*Changed in version 3.7:* For multicast addresses (with *scope\_id* meaningful) *address* may not contain *%scope\_id* (or *zone id*) part. This information is superfluous and may be safely omitted (recommended).

- **AF\_NETLINK** sockets are represented as pairs (*pid*, *groups*).
- Linux-only support for TIPC is available using the **AF\_TIPC** address family. TIPC is an open, non-IP based networked protocol designed for use in clustered computer environments. Addresses are represented by a tuple, and the fields depend on the address type. The general tuple form is (*addr\_type*, *v1*, *v2*, *v3* [, *scope*]), where:
  - *addr\_type* is one of **TIPC\_ADDR\_NAMESEQ**, **TIPC\_ADDR\_NAME**, or **TIPC\_ADDR\_ID**.
  - *scope* is one of **TIPC\_ZONE\_SCOPE**, **TIPC\_CLUSTER\_SCOPE**, and **TIPC\_NODE\_SCOPE**.
  - If *addr\_type* is **TIPC\_ADDR\_NAME**, then *v1* is the server type, *v2* is the port identifier, and *v3* should be 0.

If *addr\_type* is **TIPC\_ADDR\_NAMESEQ**, then *v1* is the server type, *v2* is the lower port number, and *v3* is the upper port number.

If *addr\_type* is **TIPC\_ADDR\_ID**, then *v1* is the node, *v2* is the reference, and *v3* should be set to 0.

- A tuple `(interface, )` is used for the **AF\_CAN** address family, where *interface* is a string representing a network interface name like `'can0'`. The network interface name `' '` can be used to receive packets from all network interfaces of this family.
  - **CAN\_ISOTP** protocol require a tuple `(interface, rx_addr, tx_addr)` where both additional parameters are unsigned long integer that represent a CAN identifier (standard or extended).
  - **CAN\_J1939** protocol require a tuple `(interface, name, pgn, addr)` where additional parameters are 64-bit unsigned integer representing the ECU name, a 32-bit unsigned integer representing the Parameter Group Number (PGN), and an 8-bit integer representing the address.
- A string or a tuple `(id, unit)` is used for the **SYSPROTO\_CONTROL** protocol of the **PF\_SYSTEM** family. The string is the name of a kernel control using a dynamically assigned ID. The tuple can be used if ID and unit number of the kernel control are known or if a registered ID is used.

*New in version 3.3.*

- **AF\_BLUETOOTH** supports the following protocols and address formats:
  - **BTPROTO\_L2CAP** accepts `(bdaddr, psm)` where `bdaddr` is the Bluetooth address as a string and `psm` is an integer.
  - **BTPROTO\_RFCOMM** accepts `(bdaddr, channel)` where `bdaddr` is the Bluetooth address as a string and `channel` is an integer.
  - **BTPROTO\_HCI** accepts `(device_id,)` where `device_id` is either an integer or a string with the Bluetooth address of the interface. (This depends on your OS; NetBSD and DragonFlyBSD expect a Bluetooth address while everything else expects an integer.)

*Changed in version 3.2:* NetBSD and DragonFlyBSD support added.

- **BTPROTO\_SCO** accepts `bdaddr` where `bdaddr` is a **bytes** object containing the Bluetooth address in a string format. (ex. `b'12:23:34:45:56:67'`) This protocol is not supported under FreeBSD.
- **AF\_ALG** is a Linux-only socket based interface to Kernel cryptography. An algorithm socket is configured with a tuple of two to four elements `(type, name [, feat [, mask]])`, where:
  - *type* is the algorithm type as string, e.g. `aead`, `hash`, `skcipher` or `rng`.
  - *name* is the algorithm name and operation mode as string, e.g. `sha256`, `hmac(sha256)`, `cbc(aes)` or `drbg_nopr_ctr_aes256`.
  - *feat* and *mask* are unsigned 32bit integers.

**Availability:** Linux  $\geq 2.6.38$ .

Some algorithm types require more recent Kernels.

*New in version 3.6.*

- **AF\_VSOCK** allows communication between virtual machines and their hosts. The sockets are represented as a `(CID, port)` tuple where the context ID or CID and port are integers.

**Availability:** Linux  $\geq 3.9$

See [`vsock\(7\)`](#)

*New in version 3.7.*

- **AF\_PACKET** is a low-level interface directly to network devices. The packets are represented by the tuple `(ifname, proto[, pkttype[, hatype[, addr]])` where:
  - *ifname* - String specifying the device name.

- *proto* - An in network-byte-order integer specifying the Ethernet protocol number.
- *pkttype* - Optional integer specifying the packet type:
  - `PACKET_HOST` (the default) - Packet addressed to the local host.
  - `PACKET_BROADCAST` - Physical-layer broadcast packet.
  - `PACKET_MULTICAST` - Packet sent to a physical-layer multicast address.
  - `PACKET_OTHERHOST` - Packet to some other host that has been caught by a device driver in promiscuous mode.
  - `PACKET_OUTGOING` - Packet originating from the local host that is looped back to a packet socket.
- *hatype* - Optional integer specifying the ARP hardware address type.
- *addr* - Optional bytes-like object specifying the hardware physical address, whose interpretation depends on the device.

**Availability:** Linux  $\geq$  2.2.

- **AF\_QIPCRTR** is a Linux-only socket based interface for communicating with services running on co-processors in Qualcomm platforms. The address family is represented as a *(node, port)* tuple where the *node* and *port* are non-negative integers.

**Availability:** Linux  $\geq$  4.7.

*New in version 3.8.*

- **IPPROTO\_UDPLITE** is a variant of UDP which allows you to specify what portion of a packet is covered with the checksum. It adds two socket options that you can change. `self.setsockopt(IPPROTO_UDPLITE, UDPLITE_SEND_CSCOV, length)` will change what portion of outgoing packets are covered by the checksum and `self.setsockopt(IPPROTO_UDPLITE, UDPLITE_RECV_CSCOV, length)` will filter out packets which cover too little of their data. In both cases `length`

should be in `range(8, 2**16, 8)`.

Such a socket should be constructed with

```
socket(AF_INET, SOCK_DGRAM, IPPROTO_UDP)
for IPv4 or socket(AF_INET6, SOCK_DGRAM,
IPPROTO_UDP) for IPv6.
```

**Availability:** Linux  $\geq$  2.6.20, FreeBSD  $\geq$  10.1

*New in version 3.9.*

If you use a hostname in the *host* portion of IPv4/v6 socket address, the program may show a nondeterministic behavior, as Python uses the first address returned from the DNS resolution. The socket address will be resolved differently into an actual IPv4/v6 address, depending on the results from DNS resolution and/or the host configuration. For deterministic behavior use a numeric address in *host* portion.

All errors raise exceptions. The normal exceptions for invalid argument types and out-of-memory conditions can be raised. Errors related to socket or address semantics raise **OSError** or one of its subclasses.

Non-blocking mode is supported through **setblocking()**. A generalization of this based on timeouts is supported through **settimeout()**.

## Module contents

The module **socket** exports the following elements.

### Exceptions

*exception* `socket.error`

A deprecated alias of **OSError**.

*Changed in version 3.3:* Following **PEP 3151** [<https://peps.python.org/pep-3151/>], this class was made an alias of **OSError**.

*exception* `socket.herror`

A subclass of `OSError`, this exception is raised for address-related errors, i.e. for functions that use `h_errno` in the POSIX C API, including `gethostbyname_ex()` and `gethostbyaddr()`. The accompanying value is a pair (`h_errno`, `string`) representing an error returned by a library call. `h_errno` is a numeric value, while `string` represents the description of `h_errno`, as returned by the `hstrerror()` C function.

*Changed in version 3.3:* This class was made a subclass of `OSError`.

*exception* `socket.gaierror`

A subclass of `OSError`, this exception is raised for address-related errors by `getaddrinfo()` and `getnameinfo()`. The accompanying value is a pair (`error`, `string`) representing an error returned by a library call. `string` represents the description of `error`, as returned by the `gai_strerror()` C function. The numeric `error` value will match one of the `EAI_*` constants defined in this module.

*Changed in version 3.3:* This class was made a subclass of `OSError`.

*exception* `socket.timeout`

A deprecated alias of `TimeoutError`.

A subclass of `OSError`, this exception is raised when a timeout occurs on a socket which has had timeouts enabled via a prior call to `settimeout()` (or implicitly through `setdefaulttimeout()`). The accompanying value is a string whose value is currently always “timed out”.

*Changed in version 3.3:* This class was made a subclass of `OSError`.

*Changed in version 3.10:* This class was made an alias of `TimeoutError`.

## Constants

The `AF_*` and `SOCK_*` constants are now **AddressFamily** and **SocketKind** [IntEnum](#) collections.

*New in version 3.4.*

`socket.AF_UNIX`  
`socket.AF_INET`  
`socket.AF_INET6`

These constants represent the address (and protocol) families, used for the first argument to `socket()`. If the [AF\\_UNIX](#) constant is not defined then this protocol is unsupported. More constants may be available depending on the system.

`socket.SOCK_STREAM`  
`socket.SOCK_DGRAM`  
`socket.SOCK_RAW`  
`socket.SOCK_RDM`  
`socket.SOCK_SEQPACKET`

These constants represent the socket types, used for the second argument to `socket()`. More constants may be available depending on the system. (Only [SOCK\\_STREAM](#) and [SOCK\\_DGRAM](#) appear to be generally useful.)

`socket.SOCK_CLOEXEC`  
`socket.SOCK_NONBLOCK`

These two constants, if defined, can be combined with the socket types and allow you to set some flags atomically (thus avoiding possible race conditions and the need for separate calls).

### See also

[Secure File Descriptor Handling](https://udrepper.livejournal.com/20407.html) [https://udrepper.livejournal.com/20407.html] for a more thorough explanation.

**Availability:** Linux  $\geq$  2.6.27.

*New in version 3.2.*

SO\_\*  
socket.SOMAXCONN  
MSG\_\*  
SOL\_\*  
SCM\_\*  
IPPROTO\_\*  
IPPORT\_\*  
INADDR\_\*  
IP\_\*  
IPV6\_\*  
EAI\_\*  
AI\_\*  
NI\_\*  
TCP\_\*

Many constants of these forms, documented in the Unix documentation on sockets and/or the IP protocol, are also defined in the socket module. They are generally used in arguments to the **setsockopt ()** and **getsockopt ()** methods of socket objects. In most cases, only those symbols that are defined in the Unix header files are defined; for a few symbols, default values are provided.

*Changed in version 3.6:* SO\_DOMAIN, SO\_PROTOCOL, SO\_PEERSEC, SO\_PASSSEC, TCP\_USER\_TIMEOUT, TCP\_CONGESTION were added.

*Changed in version 3.6.5:* On Windows, TCP\_FASTOPEN, TCP\_KEEPCNT appear if run-time Windows supports.

*Changed in version 3.7:* TCP\_NOTSENT\_LOWAT was added.

On Windows, TCP\_KEEPIRL, TCP\_KEEPIRLVL appear if run-time Windows supports.

*Changed in version 3.10:* IP\_RECVTOS was added. Added TCP\_KEEPAIVE. On MacOS this constant can be used in the same way that TCP\_KEEPIRL is used on Linux.

*Changed in version 3.11:* Added `TCP_CONNECTION_INFO`. On MacOS this constant can be used in the same way that `TCP_INFO` is used on Linux and BSD.

`socket.AF_CAN`  
`socket.PF_CAN`  
`SOL_CAN_*`  
`CAN_*`

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

**Availability:** Linux  $\geq$  2.6.25, NetBSD  $\geq$  8.

*New in version 3.3.*

*Changed in version 3.11:* NetBSD support was added.

`socket.CAN_BCM`  
`CAN_BCM_*`

`CAN_BCM`, in the CAN protocol family, is the broadcast manager (BCM) protocol. Broadcast manager constants, documented in the Linux documentation, are also defined in the socket module.

**Availability:** Linux  $\geq$  2.6.25.

### Note

The `CAN_BCM_CAN_FD_FRAME` flag is only available on Linux  $\geq$  4.8.

*New in version 3.4.*

`socket.CAN_RAW_FD_FRAMES`

Enables CAN FD support in a `CAN_RAW` socket. This is disabled by default. This allows your application to send both CAN and CAN FD frames; however, you must accept both CAN and CAN FD frames when reading from the socket.

This constant is documented in the Linux documentation.

**Availability:** Linux  $\geq$  3.6.

*New in version 3.5.*

socket.CAN\_RAW\_JOIN\_FILTERS

Joins the applied CAN filters such that only CAN frames that match all given CAN filters are passed to user space.

This constant is documented in the Linux documentation.

**Availability:** Linux  $\geq$  4.1.

*New in version 3.9.*

socket.CAN\_ISOTP

CAN\_ISOTP, in the CAN protocol family, is the ISO-TP (ISO 15765-2) protocol. ISO-TP constants, documented in the Linux documentation.

**Availability:** Linux  $\geq$  2.6.25.

*New in version 3.7.*

socket.CAN\_J1939

CAN\_J1939, in the CAN protocol family, is the SAE J1939 protocol. J1939 constants, documented in the Linux documentation.

**Availability:** Linux  $\geq$  5.4.

*New in version 3.9.*

socket.AF\_PACKET

socket.PF\_PACKET

PACKET\_\*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

**Availability:** Linux  $\geq$  2.2.

socket.AF\_RDS  
socket.PF\_RDS  
socket.SOL\_RDS  
RDS\_\*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

**Availability:** Linux  $\geq$  2.6.30.

*New in version 3.3.*

socket.SIO\_RCVALL  
socket.SIO\_KEEPALIVE\_VALS  
socket.SIO\_LOOPBACK\_FAST\_PATH  
RCVALL\_\*

Constants for Windows' WSAIoctl(). The constants are used as arguments to the `ioctl()` method of socket objects.

*Changed in version 3.6:* SIO\_LOOPBACK\_FAST\_PATH was added.

TIPC\_\*

TIPC related constants, matching the ones exported by the C socket API. See the TIPC documentation for more information.

socket.AF\_ALG  
socket.SOL\_ALG  
ALG\_\*

Constants for Linux Kernel cryptography.

**Availability:** Linux  $\geq$  2.6.38.

*New in version 3.6.*

socket.AF\_VSOCK  
socket.IOCTL\_VM\_SOCKETS\_GET\_LOCAL\_CID  
VMADDR\*  
SO\_VM\*

Constants for Linux host/guest communication.

**Availability:** Linux  $\geq$  4.8.

*New in version 3.7.*

socket.AF\_LINK

**Availability:** BSD, macOS.

*New in version 3.4.*

socket.has\_ipv6

This constant contains a boolean value which indicates if IPv6 is supported on this platform.

socket.BDADDR\_ANY

socket.BDADDR\_LOCAL

These are string constants containing Bluetooth addresses with special meanings. For example, **BDADDR\_ANY** can be used to indicate any address when specifying the binding socket with **BTPROTO\_RFCOMM**.

socket.HCI\_FILTER

socket.HCI\_TIME\_STAMP

socket.HCI\_DATA\_DIR

For use with **BTPROTO\_HCI**. **HCI\_FILTER** is not available for NetBSD or DragonFlyBSD. **HCI\_TIME\_STAMP** and **HCI\_DATA\_DIR** are not available for FreeBSD, NetBSD, or DragonFlyBSD.

socket.AF\_QIPCRTR

Constant for Qualcomm's IPC router protocol, used to communicate with service providing remote processors.

**Availability:** Linux  $\geq$  4.7.

socket.SCM\_CREDS2

socket.LOCAL\_CREDS

socket.LOCAL\_CREDS\_PERSISTENT

LOCAL\_CREDS and LOCAL\_CREDS\_PERSISTENT can be used with SOCK\_DGRAM, SOCK\_STREAM sockets, equivalent to Linux/DragonFlyBSD SO\_PASSCRED, while LOCAL\_CREDS sends the credentials at first read, LOCAL\_CREDS\_PERSISTENT sends for each read, SCM\_CREDS2 must be then used for the latter for the message type.

*New in version 3.11.*

**Availability:** FreeBSD.

socket.SO\_INCOMING\_CPU

Constant to optimize CPU locality, to be used in conjunction with **SO\_REUSEPORT**.

*New in version 3.11.*

**Availability:** Linux >= 3.9

## Functions

### Creating sockets

The following functions all create [socket objects](#).

```
class socket.socket(family=AF_INET, type=SOCK_STREAM,  
proto=0, fileno=None)
```

Create a new socket using the given address family, socket type and protocol number. The address family should be [AF\\_INET](#) (the default), [AF\\_INET6](#), [AF\\_UNIX](#), [AF\\_CAN](#), [AF\\_PACKET](#), or [AF\\_RDS](#). The socket type should be [SOCK\\_STREAM](#) (the default), [SOCK\\_DGRAM](#), [SOCK\\_RAW](#) or perhaps one of the other `SOCK_` constants. The protocol number is usually zero and may be omitted or in the case where the address family is [AF\\_CAN](#) the protocol should be one of [CAN\\_RAW](#), [CAN\\_BCM](#), [CAN\\_ISOTP](#) or [CAN\\_J1939](#).

If *fileno* is specified, the values for *family*, *type*, and *proto* are

auto-detected from the specified file descriptor. Auto-detection can be overruled by calling the function with explicit *family*, *type*, or *proto* arguments. This only affects how Python represents e.g. the return value of `socket.getpeername()` but not the actual OS resource. Unlike `socket.fromfd()`, *fileno* will return the same socket and not a duplicate. This may help close a detached socket using `socket.close()`.

The newly created socket is [non-inheritable](#).

Raises an [auditing event](#) `socket.__new__` with arguments `self`, `family`, `type`, `protocol`.

*Changed in version 3.3:* The AF\_CAN family was added. The AF\_RDS family was added.

*Changed in version 3.4:* The CAN\_BCM protocol was added.

*Changed in version 3.4:* The returned socket is now non-inheritable.

*Changed in version 3.7:* The CAN\_ISOTP protocol was added.

*Changed in version 3.7:* When [SOCK\\_NONBLOCK](#) or [SOCK\\_CLOEXEC](#) bit flags are applied to *type* they are cleared, and `socket.type` will not reflect them. They are still passed to the underlying system `socket()` call. Therefore,

```
sock = socket.socket(  
    socket.AF_INET,  
    socket.SOCK_STREAM | socket.SOCK_NONBLOCK)
```

will still create a non-blocking socket on OSes that support SOCK\_NONBLOCK, but `sock.type` will be set to `socket.SOCK_STREAM`.

*Changed in version 3.9:* The CAN\_J1939 protocol was added.

*Changed in version 3.10:* The IPPROTO\_MPTCP protocol was added.

`socket.socketpair([family[, type[, proto]]])`

Build a pair of connected socket objects using the given address family, socket type, and protocol number. Address family, socket type, and protocol number are as for the **socket ()** function above. The default family is **AF\_UNIX** if defined on the platform; otherwise, the default is **AF\_INET**.

The newly created sockets are **non-inheritable**.

*Changed in version 3.2:* The returned socket objects now support the whole socket API, rather than a subset.

*Changed in version 3.4:* The returned sockets are now non-inheritable.

*Changed in version 3.5:* Windows support added.

`socket.create_connection(address, timeout=GLOBAL_DEFAULT,  
source_address=None, *, all_errors=False)`

Connect to a TCP service listening on the internet *address* (a 2-tuple (host, port)), and return the socket object. This is a higher-level function than **socket.connect ()**: if *host* is a non-numeric hostname, it will try to resolve it for both **AF\_INET** and **AF\_INET6**, and then try to connect to all possible addresses in turn until a connection succeeds. This makes it easy to write clients that are compatible to both IPv4 and IPv6.

Passing the optional *timeout* parameter will set the timeout on the socket instance before attempting to connect. If no *timeout* is supplied, the global default timeout setting returned by **getdefaulttimeout ()** is used.

If supplied, *source\_address* must be a 2-tuple (host, port) for the socket to bind to as its source address before connecting. If host or port are '' or 0 respectively the OS default behavior will be used.

When a connection cannot be created, an exception is raised. By default, it is the exception from the last address in the list.

If `all_errors` is `True`, it is an `ExceptionGroup` containing the errors of all attempts.

*Changed in version 3.2:* `source_address` was added.

*Changed in version 3.11:* `all_errors` was added.

```
socket.create_server(address, *, family=AF_INET, backlog=None,
reuse_port=False, dualstack_ipv6=False)
```

Convenience function which creates a TCP socket bound to `address` (a 2-tuple (host, port)) and return the socket object.

`family` should be either `AF_INET` or `AF_INET6`. `backlog` is the queue size passed to `socket.listen()`; if not specified, a default reasonable value is chosen. `reuse_port` dictates whether to set the `SO_REUSEPORT` socket option.

If `dualstack_ipv6` is true and the platform supports it the socket will be able to accept both IPv4 and IPv6 connections, else it will raise `ValueError`. Most POSIX platforms and Windows are supposed to support this functionality. When this functionality is enabled the address returned by `socket.getpeername()` when an IPv4 connection occurs will be an IPv6 address represented as an IPv4-mapped IPv6 address. If `dualstack_ipv6` is false it will explicitly disable this functionality on platforms that enable it by default (e.g. Linux). This parameter can be used in conjunction with `has_dualstack_ipv6()`:

```
import socket
```

```
addr = ("", 8080) # all interfaces, port 8080
if socket.has_dualstack_ipv6():
    s = socket.create_server(addr, family=socket.AF_INET6)
else:
    s = socket.create_server(addr)
```

## Note

On POSIX platforms the `SO_REUSEADDR` socket option is set in order to immediately reuse previous sockets which were bound on the same *address* and remained in `TIME_WAIT` state.

*New in version 3.8.*

`socket.has_dualstack_ipv6()`

Return `True` if the platform supports creating a TCP socket which can handle both IPv4 and IPv6 connections.

*New in version 3.8.*

`socket.fromfd(fd, family, type, proto=0)`

Duplicate the file descriptor *fd* (an integer as returned by a file object's `fileno()` method) and build a socket object from the result. Address family, socket type and protocol number are as for the `socket()` function above. The file descriptor should refer to a socket, but this is not checked — subsequent operations on the object may fail if the file descriptor is invalid. This function is rarely needed, but can be used to get or set socket options on a socket passed to a program as standard input or output (such as a server started by the Unix `inet` daemon). The socket is assumed to be in blocking mode.

The newly created socket is [non-inheritable](#).

*Changed in version 3.4:* The returned socket is now non-inheritable.

`socket.fromshare(data)`

Instantiate a socket from data obtained from the [socket.share\(\)](#) method. The socket is assumed to be in blocking mode.

[Availability](#): Windows.

*New in version 3.3.*

## socket.SocketType

This is a Python type object that represents the socket object type. It is the same as `type(socket(...))`.

## Other functions

The `socket` module also offers various network-related services:

### `socket.close(fd)`

Close a socket file descriptor. This is like `os.close()`, but for sockets. On some platforms (most noticeable Windows) `os.close()` does not work for socket file descriptors.

*New in version 3.7.*

### `socket.getaddrinfo(host, port, family=0, type=0, proto=0, flags=0)`

Translate the *host/port* argument into a sequence of 5-tuples that contain all the necessary arguments for creating a socket connected to that service. *host* is a domain name, a string representation of an IPv4/v6 address or `None`. *port* is a string service name such as `'http'`, a numeric port number or `None`. By passing `None` as the value of *host* and *port*, you can pass `NULL` to the underlying C API.

The *family*, *type* and *proto* arguments can be optionally specified in order to narrow the list of addresses returned. Passing zero as a value for each of these arguments selects the full range of results. The *flags* argument can be one or several of the `AI_*` constants, and will influence how results are computed and returned. For example, `AI_NUMERICHOST` will disable domain name resolution and will raise an error if *host* is a domain name.

The function returns a list of 5-tuples with the following structure:

```
(family, type, proto, canonname, sockaddr)
```

In these tuples, *family*, *type*, *proto* are all integers and are

meant to be passed to the `socket()` function. *canonicalname* will be a string representing the canonical name of the *host* if **AI\_CANONNAME** is part of the *flags* argument; else *canonicalname* will be empty. *sockaddr* is a tuple describing a socket address, whose format depends on the returned *family* (a (address, port) 2-tuple for **AF\_INET**, a (address, port, flowinfo, scope\_id) 4-tuple for **AF\_INET6**), and is meant to be passed to the `socket.connect()` method.

Raises an **auditing event** `socket.getaddrinfo` with arguments *host*, *port*, *family*, *type*, *protocol*.

The following example fetches address information for a hypothetical TCP connection to `example.org` on port 80 (results may differ on your system if IPv6 isn't enabled):

```
>>> socket.getaddrinfo("example.org", 80, proto=soc
[(socket.AF_INET6, socket.SOCK_STREAM,
 6, '', ('2606:2800:220:1:248:1893:25c8:1946', 80,
(socket.AF_INET, socket.SOCK_STREAM,
 6, '', ('93.184.216.34', 80)))]
```

*Changed in version 3.2:* parameters can now be passed using keyword arguments.

*Changed in version 3.7:* for IPv6 multicast addresses, string representing an address will not contain `%scope_id` part.

`socket.getfqdn([name])`

Return a fully qualified domain name for *name*. If *name* is omitted or empty, it is interpreted as the local host. To find the fully qualified name, the hostname returned by **gethostbyaddr()** is checked, followed by aliases for the host, if available. The first name which includes a period is selected. In case no fully qualified domain name is available and *name* was provided, it is returned unchanged. If *name* was empty or equal to `'0.0.0.0'`, the hostname from **gethostname()** is returned.

`socket.gethostbyname(hostname)`

Translate a host name to IPv4 address format. The IPv4 address is returned as a string, such as `'100.50.200.5'`. If the host name is an IPv4 address itself it is returned unchanged. See `gethostbyname_ex()` for a more complete interface. `gethostbyname()` does not support IPv6 name resolution, and `getaddrinfo()` should be used instead for IPv4/v6 dual stack support.

Raises an [auditing event](#) `socket.gethostbyname` with argument `hostname`.

[Availability](#): not WASI.

`socket.gethostbyname_ex(hostname)`

Translate a host name to IPv4 address format, extended interface. Return a triple `(hostname, aliaslist, ipaddrlist)` where *hostname* is the host's primary host name, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4 addresses for the same interface on the same host (often but not always a single address). `gethostbyname_ex()` does not support IPv6 name resolution, and `getaddrinfo()` should be used instead for IPv4/v6 dual stack support.

Raises an [auditing event](#) `socket.gethostbyname` with argument `hostname`.

[Availability](#): not WASI.

`socket.gethostname()`

Return a string containing the hostname of the machine where the Python interpreter is currently executing.

Raises an [auditing event](#) `socket.gethostname` with no arguments.

Note: `gethostname()` doesn't always return the fully qualified domain name; use `getfqdn()` for that.

[Availability](#): not WASI.

`socket.gethostbyaddr(ip_address)`

Return a triple (*hostname*, *aliaslist*, *ipaddrlist*) where *hostname* is the primary host name responding to the given *ip\_address*, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4/v6 addresses for the same interface on the same host (most likely containing only a single address). To find the fully qualified domain name, use the function [getfqdn\(\)](#). [gethostbyaddr\(\)](#) supports both IPv4 and IPv6.

Raises an [auditing event](#) `socket.gethostbyaddr` with argument `ip_address`.

[Availability](#): not WASI.

`socket.getnameinfo(sockaddr, flags)`

Translate a socket address *sockaddr* into a 2-tuple (*host*, *port*). Depending on the settings of *flags*, the result can contain a fully qualified domain name or numeric address representation in *host*. Similarly, *port* can contain a string port name or a numeric port number.

For IPv6 addresses, `%scope_id` is appended to the host part if *sockaddr* contains meaningful *scope\_id*. Usually this happens for multicast addresses.

For more information about *flags* you can consult [getnameinfo\(3\)](#).

Raises an [auditing event](#) `socket.getnameinfo` with argument `sockaddr`.

[Availability](#): not WASI.

`socket.getprotobyname(protocolname)`

Translate an internet protocol name (for example, `'icmp'`) to a constant suitable for passing as the (optional) third argument to the `socket()` function. This is usually only

needed for sockets opened in “raw” mode ([SOCK\\_RAW](#)); for the normal socket modes, the correct protocol is chosen automatically if the protocol is omitted or zero.

[Availability](#): not WASI.

`socket.getservbyname(servicename[, protocolname])`

Translate an internet service name and protocol name to a port number for that service. The optional protocol name, if given, should be 'tcp' or 'udp', otherwise any protocol will match.

Raises an [auditing event](#) `socket.getservbyname` with arguments `servicename`, `protocolname`.

[Availability](#): not WASI.

`socket.getservbyport(port[, protocolname])`

Translate an internet port number and protocol name to a service name for that service. The optional protocol name, if given, should be 'tcp' or 'udp', otherwise any protocol will match.

Raises an [auditing event](#) `socket.getservbyport` with arguments `port`, `protocolname`.

[Availability](#): not WASI.

`socket.ntohl(x)`

Convert 32-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

`socket.ntohs(x)`

Convert 16-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a

2-byte swap operation.

*Changed in version 3.10:* Raises `OverflowError` if `x` does not fit in a 16-bit unsigned integer.

`socket.htonl(x)`

Convert 32-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

`socket.htons(x)`

Convert 16-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

*Changed in version 3.10:* Raises `OverflowError` if `x` does not fit in a 16-bit unsigned integer.

`socket.inet_aton(ip_string)`

Convert an IPv4 address from dotted-quad string format (for example, '123.45.67.89') to 32-bit packed binary format, as a bytes object four characters in length. This is useful when conversing with a program that uses the standard C library and needs objects of type `in_addr`, which is the C type for the 32-bit packed binary this function returns.

`inet_aton()` also accepts strings with less than three dots; see the Unix manual page [`inet\(3\)`](#) for details.

If the IPv4 address string passed to this function is invalid, `OSError` will be raised. Note that exactly what is valid depends on the underlying C implementation of `inet_aton()`.

`inet_aton()` does not support IPv6, and `inet_pton()` should be used instead for IPv4/v6 dual stack support.

`socket.inet_ntoa(packed_ip)`

Convert a 32-bit packed IPv4 address (a [bytes-like object](#) four bytes in length) to its standard dotted-quad string representation (for example, '123.45.67.89'). This is useful when conversing with a program that uses the standard C library and needs objects of type `in_addr`, which is the C type for the 32-bit packed binary data this function takes as an argument.

If the byte sequence passed to this function is not exactly 4 bytes in length, `OSError` will be raised. `inet_ntoa()` does not support IPv6, and `inet_ntop()` should be used instead for IPv4/v6 dual stack support.

*Changed in version 3.5:* Writable [bytes-like object](#) is now accepted.

`socket.inet_pton(address_family, ip_string)`

Convert an IP address from its family-specific string format to a packed, binary format. `inet_pton()` is useful when a library or network protocol calls for an object of type `in_addr` (similar to `inet_aton()`) or `in6_addr`.

Supported values for *address\_family* are currently `AF_INET` and `AF_INET6`. If the IP address string *ip\_string* is invalid, `OSError` will be raised. Note that exactly what is valid depends on both the value of *address\_family* and the underlying implementation of `inet_pton()`.

[Availability:](#) Unix, Windows.

*Changed in version 3.4:* Windows support added

`socket.inet_ntop(address_family, packed_ip)`

Convert a packed IP address (a [bytes-like object](#) of some number of bytes) to its standard, family-specific string representation (for example, '7.10.0.5' or '5aef:2b::8'). `inet_ntop()` is useful when a library or network protocol returns an object of type `in_addr` (similar

to `inet_ntoa()` or `in6_addr`.

Supported values for *address\_family* are currently `AF_INET` and `AF_INET6`. If the bytes object *packed\_ip* is not the correct length for the specified address family, `ValueError` will be raised. `OSError` is raised for errors from the call to `inet_ntop()`.

**Availability:** Unix, Windows.

*Changed in version 3.4:* Windows support added

*Changed in version 3.5:* Writable **bytes-like object** is now accepted.

`socket.CMSG_LEN(length)`

Return the total length, without trailing padding, of an ancillary data item with associated data of the given *length*. This value can often be used as the buffer size for `recvmsg()` to receive a single item of ancillary data, but **RFC 3542** [<https://datatracker.ietf.org/doc/html/rfc3542.html>] requires portable applications to use `CMSG_SPACE()` and thus include space for padding, even when the item will be the last in the buffer. Raises `OverflowError` if *length* is outside the permissible range of values.

**Availability:** Unix, not Emscripten, not WASI.

Most Unix platforms.

*New in version 3.3.*

`socket.CMSG_SPACE(length)`

Return the buffer size needed for `recvmsg()` to receive an ancillary data item with associated data of the given *length*, along with any trailing padding. The buffer space needed to receive multiple items is the sum of the `CMSG_SPACE()` values for their associated data lengths. Raises `OverflowError` if *length* is outside the permissible range of values.

Note that some systems might support ancillary data without providing this function. Also note that setting the buffer size using the results of this function may not precisely limit the amount of ancillary data that can be received, since additional data may be able to fit into the padding area.

**Availability:** Unix, not Emscripten, not WASI.

most Unix platforms.

*New in version 3.3.*

`socket.getdefaulttimeout()`

Return the default timeout in seconds (float) for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

`socket.setdefaulttimeout(timeout)`

Set the default timeout in seconds (float) for new socket objects. When the socket module is first imported, the default is `None`. See [`settimeout\(\)`](#) for possible values and their respective meanings.

`socket.sethostname(name)`

Set the machine's hostname to *name*. This will raise an [`OSError`](#) if you don't have enough rights.

Raises an [auditing event](#) `socket.sethostname` with argument `name`.

**Availability:** Unix.

*New in version 3.3.*

`socket.if_nameindex()`

Return a list of network interface information (index int, name string) tuples. [`OSError`](#) if the system call fails.

**Availability:** Unix, Windows, not Emscripten, not WASI.

*New in version 3.3.*

*Changed in version 3.8:* Windows support was added.

### Note

On Windows network interfaces have different names in different contexts (all names are examples):

- **UUID:** {FB605B73-AAC2-49A6-9A2F-25416AEA0573}
- **name:** ethernet\_32770
- **friendly name:** vEthernet (nat)
- **description:** Hyper-V Virtual Ethernet Adapter

This function returns names of the second form from the list, `ethernet_32770` in this example case.

`socket.if_nametoindex(if_name)`

Return a network interface index number corresponding to an interface name. **OSError** if no interface with the given name exists.

**Availability:** Unix, Windows, not Emscripten, not WASI.

*New in version 3.3.*

*Changed in version 3.8:* Windows support was added.

### See also

“Interface name” is a name as documented in [`if\_nameindex\(\)`](#).

`socket.if_indextoname(if_index)`

Return a network interface name corresponding to an interface index number. **OSError** if no interface with the given index exists.

**Availability:** Unix, Windows, not Emscripten, not WASI.

*New in version 3.3.*

*Changed in version 3.8:* Windows support was added.

### See also

“Interface name” is a name as documented in **if\_nameindex()**.

`socket.send_fds(sock, buffers, fds[, flags[, address]])`

Send the list of file descriptors *fds* over an **AF\_UNIX** socket *sock*. The *fds* parameter is a sequence of file descriptors. Consult **sendmsg()** for the documentation of these parameters.

**Availability:** Unix, Windows, not Emscripten, not WASI.

Unix platforms supporting **sendmsg()** and **SCM\_RIGHTS** mechanism.

*New in version 3.9.*

`socket.recv_fds(sock, bufsize, maxfds[, flags])`

Receive up to *maxfds* file descriptors from an **AF\_UNIX** socket *sock*. Return `(msg, list(fds), flags, addr)`. Consult **recvmsg()** for the documentation of these parameters.

**Availability:** Unix, Windows, not Emscripten, not WASI.

Unix platforms supporting **sendmsg()** and **SCM\_RIGHTS** mechanism.

*New in version 3.9.*

### Note

Any truncated integers at the end of the list of file descriptors.

## Socket Objects

Socket objects have the following methods. Except for `makefile()`, these correspond to Unix system calls applicable to sockets.

*Changed in version 3.2:* Support for the `context manager` protocol was added. Exiting the context manager is equivalent to calling `close()`.

`socket.accept()`

Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where *conn* is a *new* socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection.

The newly created socket is `non-inheritable`.

*Changed in version 3.4:* The socket is now non-inheritable.

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](https://peps.python.org/pep-0475/) [https://peps.python.org/pep-0475/] for the rationale).

`socket.bind(address)`

Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family

— see above.)

Raises an [auditing event](#) `socket.bind` with arguments `self`, `address`.

[Availability](#): not WASI.

## `socket.close()`

Mark the socket closed. The underlying system resource (e.g. a file descriptor) is also closed when all file objects from [makefile\(\)](#) are closed. Once that happens, all future operations on the socket object will fail. The remote end will receive no more data (after queued data is flushed).

Sockets are automatically closed when they are garbage-collected, but it is recommended to [close\(\)](#) them explicitly, or to use a [with](#) statement around them.

*Changed in version 3.6:* [OSError](#) is now raised if an error occurs when the underlying [close\(\)](#) call is made.

### Note

[close\(\)](#) releases the resource associated with a connection but does not necessarily close the connection immediately. If you want to close the connection in a timely fashion, call [shutdown\(\)](#) before [close\(\)](#).

## `socket.connect(address)`

Connect to a remote socket at *address*. (The format of *address* depends on the address family — see above.)

If the connection is interrupted by a signal, the method waits until the connection completes, or raise a [TimeoutError](#) on timeout, if the signal handler doesn't raise an exception and the socket is blocking or has a timeout. For non-blocking sockets, the method raises an [InterruptedError](#) exception if the connection is interrupted by a signal (or the exception raised by the signal handler).

Raises an [auditing event](#) `socket.connect` with arguments `self`, `address`.

*Changed in version 3.5:* The method now waits until the connection completes instead of raising an [InterruptedError](#) exception if the connection is interrupted by a signal, the signal handler doesn't raise an exception and the socket is blocking or has a timeout (see the [PEP 475](#) [<https://peps.python.org/pep-0475/>] for the rationale).

[Availability](#): not WASI.

`socket.connect_ex(address)`

Like `connect(address)`, but return an error indicator instead of raising an exception for errors returned by the C-level `connect()` call (other problems, such as “host not found,” can still raise exceptions). The error indicator is `0` if the operation succeeded, otherwise the value of the `errno` variable. This is useful to support, for example, asynchronous connects.

Raises an [auditing event](#) `socket.connect` with arguments `self`, `address`.

[Availability](#): not WASI.

`socket.detach()`

Put the socket object into closed state without actually closing the underlying file descriptor. The file descriptor is returned, and can be reused for other purposes.

*New in version 3.2.*

`socket.dup()`

Duplicate the socket.

The newly created socket is [non-inheritable](#).

*Changed in version 3.4:* The socket is now non-inheritable.

**Availability:** not WASI.

`socket.fileno()`

Return the socket's file descriptor (a small integer), or -1 on failure. This is useful with `select.select()`.

Under Windows the small integer returned by this method cannot be used where a file descriptor can be used (such as `os.fdopen()`). Unix does not have this limitation.

`socket.get_inheritable()`

Get the **inheritable flag** of the socket's file descriptor or socket's handle: `True` if the socket can be inherited in child processes, `False` if it cannot.

*New in version 3.4.*

`socket.getpeername()`

Return the remote address to which the socket is connected. This is useful to find out the port number of a remote IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.) On some systems this function is not supported.

`socket.getsockname()`

Return the socket's own address. This is useful to find out the port number of an IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.)

`socket.getsockopt(level, optname[, buflen])`

Return the value of the given socket option (see the Unix man page `getsockopt(2)`). The needed symbolic constants (`SO_*` etc.) are defined in this module. If `buflen` is absent, an integer option is assumed and its integer value is returned by the function. If `buflen` is present, it specifies the maximum length of the buffer used to receive the option in, and this buffer is

returned as a bytes object. It is up to the caller to decode the contents of the buffer (see the optional built-in module `struct` for a way to decode C structures encoded as byte strings).

**Availability:** not WASI.

`socket.getblocking()`

Return `True` if socket is in blocking mode, `False` if in non-blocking.

This is equivalent to checking `socket.gettimeout() != 0`.

*New in version 3.7.*

`socket.gettimeout()`

Return the timeout in seconds (float) associated with socket operations, or `None` if no timeout is set. This reflects the last call to `setblocking()` or `settimeout()`.

`socket.ioctl(control, option)`

## Platform

### Windows

The `ioctl()` method is a limited interface to the `WSAIoctl` system interface. Please refer to the [Win32 documentation](https://msdn.microsoft.com/en-us/library/ms741621%28VS.85%29.aspx) [https://msdn.microsoft.com/en-us/library/ms741621%28VS.85%29.aspx] for more information.

On other platforms, the generic `fcntl.fcntl()` and `fcntl.ioctl()` functions may be used; they accept a socket object as their first argument.

Currently only the following control codes are supported:

`SIO_RCVALL`, `SIO_KEEPAIVE_VALS`, and `SIO_LOOPBACK_FAST_PATH`.

*Changed in version 3.6:* `SIO_LOOPBACK_FAST_PATH` was

added.

`socket.listen([backlog])`

Enable a server to accept connections. If *backlog* is specified, it must be at least 0 (if it is lower, it is set to 0); it specifies the number of unaccepted connections that the system will allow before refusing new connections. If not specified, a default reasonable value is chosen.

**Availability:** not WASI.

*Changed in version 3.5:* The *backlog* parameter is now optional.

`socket.makefile(mode='r', buffering=None, *, encoding=None, errors=None, newline=None)`

Return a [file object](#) associated with the socket. The exact returned type depends on the arguments given to `makefile()`. These arguments are interpreted the same way as by the built-in `open()` function, except the only supported *mode* values are 'r' (default), 'w' and 'b'.

The socket must be in blocking mode; it can have a timeout, but the file object's internal buffer may end up in an inconsistent state if a timeout occurs.

Closing the file object returned by `makefile()` won't close the original socket unless all other file objects have been closed and `socket.close()` has been called on the socket object.

### Note

On Windows, the file-like object created by `makefile()` cannot be used where a file object with a file descriptor is expected, such as the stream arguments of `subprocess.Popen()`.

`socket.recv(bufsize[, flags])`

Receive data from the socket. The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by *bufsize*. See the Unix manual page [recv\(2\)](#) for the meaning of the optional argument *flags*; it defaults to zero.

### Note

For best match with hardware and network realities, the value of *bufsize* should be a relatively small power of 2, for example, 4096.

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an **InterruptedError** exception (see [PEP 475](#) [<https://peps.python.org/pep-0475/>] for the rationale).

`socket.recvfrom(bufsize[, flags])`

Receive data from the socket. The return value is a pair (bytes, address) where *bytes* is a bytes object representing the data received and *address* is the address of the socket sending the data. See the Unix manual page [recv\(2\)](#) for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.)

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an **InterruptedError** exception (see [PEP 475](#) [<https://peps.python.org/pep-0475/>] for the rationale).

*Changed in version 3.7:* For multicast IPv6 address, first item of *address* does not contain `%scope_id` part anymore. In order to get full IPv6 address use [getnameinfo\(\)](#).

`socket.recvmsg(bufsize[, ancbufsize[, flags]])`

Receive normal data (up to *bufsize* bytes) and ancillary data

from the socket. The *ancbufsize* argument sets the size in bytes of the internal buffer used to receive the ancillary data; it defaults to 0, meaning that no ancillary data will be received. Appropriate buffer sizes for ancillary data can be calculated using `CMSG_SPACE()` or `CMSG_LEN()`, and items which do not fit into the buffer might be truncated or discarded. The *flags* argument defaults to 0 and has the same meaning as for `recv()`.

The return value is a 4-tuple: (*data*, *ancdata*, *msg\_flags*, *address*). The *data* item is a `bytes` object holding the non-ancillary data received. The *ancdata* item is a list of zero or more tuples (*cmsg\_level*, *cmsg\_type*, *cmsg\_data*) representing the ancillary data (control messages) received: *cmsg\_level* and *cmsg\_type* are integers specifying the protocol level and protocol-specific type respectively, and *cmsg\_data* is a `bytes` object holding the associated data. The *msg\_flags* item is the bitwise OR of various flags indicating conditions on the received message; see your system documentation for details. If the receiving socket is unconnected, *address* is the address of the sending socket, if available; otherwise, its value is unspecified.

On some systems, `sendmsg()` and `recvmsg()` can be used to pass file descriptors between processes over an `AF_UNIX` socket. When this facility is used (it is often restricted to `SOCK_STREAM` sockets), `recvmsg()` will return, in its ancillary data, items of the form (`socket.SOL_SOCKET`, `socket.SCM_RIGHTS`, *fds*), where *fds* is a `bytes` object representing the new file descriptors as a binary array of the native C int type. If `recvmsg()` raises an exception after the system call returns, it will first attempt to close any file descriptors received via this mechanism.

Some systems do not indicate the truncated length of ancillary data items which have been only partially received. If an item appears to extend beyond the end of the buffer, `recvmsg()` will issue a `RuntimeWarning`, and will return the part of it which is inside the buffer provided it has not been truncated before the start of its associated data.

On systems which support the **SCM\_RIGHTS** mechanism, the following function will receive up to *maxfds* file descriptors, returning the message data and a list containing the descriptors (while ignoring unexpected conditions such as unrelated control messages being received). See also [sendmsg\(\)](#).

```
import socket, array

def recv_fds(sock, msglen, maxfds):
    fds = array.array("i")    # Array of ints
    msg, ancdata, flags, addr = sock.recvmsg(msglen,
    for cmsg_level, cmsg_type, cmsg_data in ancdata:
        if cmsg_level == socket.SOL_SOCKET and cmsg_type == socket.SCM_RIGHTS:
            # Append data, ignoring any truncated data
            fds.frombytes(cmsg_data[:len(cmsg_data) - 4])
    return msg, list(fds)
```

**Availability:** Unix.

Most Unix platforms.

*New in version 3.3.*

**Changed in version 3.5:** If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an **InterruptedError** exception (see [PEP 475](#) [<https://peps.python.org/pep-0475/>] for the rationale).

`socket.recvmsg_into(buffers[, ancbufsize[, flags]])`

Receive normal data and ancillary data from the socket, behaving as [recvmsg\(\)](#) would, but scatter the non-ancillary data into a series of buffers instead of returning a new bytes object. The *buffers* argument must be an iterable of objects that export writable buffers (e.g. [bytearray](#) objects); these will be filled with successive chunks of the non-ancillary data until it has all been written or there are no more buffers. The operating system may set a limit ([sysconf\(\)](#) value `SC_IOV_MAX`) on the number of buffers that can be used. The

*ancbufsize* and *flags* arguments have the same meaning as for `recvmsg()`.

The return value is a 4-tuple: (*nbytes*, *ancdata*, *msg\_flags*, *address*), where *nbytes* is the total number of bytes of non-ancillary data written into the buffers, and *ancdata*, *msg\_flags* and *address* are the same as for `recvmsg()`.

Example:

```
>>> import socket
>>> s1, s2 = socket.socketpair()
>>> b1 = bytearray(b'----')
>>> b2 = bytearray(b'0123456789')
>>> b3 = bytearray(b'-----')
>>> s1.send(b'Mary had a little lamb')
22
>>> s2.recvmsg_into([b1, memoryview(b2)[2:9], b3])
(22, [], 0, None)
>>> [b1, b2, b3]
[bytearray(b'Mary'), bytearray(b'01 had a 9'), byte
```

**Availability:** Unix.

Most Unix platforms.

*New in version 3.3.*

`socket.recvfrom_into(buffer[, nbytes[, flags]])`

Receive data from the socket, writing it into *buffer* instead of creating a new bytestring. The return value is a pair (*nbytes*, *address*) where *nbytes* is the number of bytes received and *address* is the address of the socket sending the data. See the Unix manual page [recv\(2\)](#) for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.)

`socket.recv_into(buffer[, nbytes[, flags]])`

Receive up to *nbytes* bytes from the socket, storing the data into a buffer rather than creating a new bytestring. If *nbytes* is not specified (or 0), receive up to the size available in the given buffer. Returns the number of bytes received. See the Unix manual page [recv\(2\)](#) for the meaning of the optional argument *flags*; it defaults to zero.

`socket.send(bytes[, flags])`

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for [recv\(\)](#) above. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data. For further information on this topic, consult the [Socket Programming HOWTO](#).

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an [InterruptedError](#) exception (see [PEP 475](#) [<https://peps.python.org/pep-0475/>] for the rationale).

`socket.sendall(bytes[, flags])`

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for [recv\(\)](#) above. Unlike [send\(\)](#), this method continues to send data from *bytes* until either all data has been sent or an error occurs. `None` is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

*Changed in version 3.5:* The socket timeout is no longer reset each time data is sent successfully. The socket timeout is now the maximum total duration to send all data.

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an

**InterruptedError** exception (see [PEP 475](https://peps.python.org/pep-0475/) [https://peps.python.org/pep-0475/] for the rationale).

`socket.sendto(bytes, address)`

`socket.sendto(bytes, flags, address)`

Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by *address*. The optional *flags* argument has the same meaning as for `recv()` above. Return the number of bytes sent. (The format of *address* depends on the address family — see above.)

Raises an [auditing event](#) `socket.sendto` with arguments `self, address`.

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an **InterruptedError** exception (see [PEP 475](https://peps.python.org/pep-0475/) [https://peps.python.org/pep-0475/] for the rationale).

`socket.sendmsg(buffers[, ancdata[, flags[, address]]])`

Send normal and ancillary data to the socket, gathering the non-ancillary data from a series of buffers and concatenating it into a single message. The *buffers* argument specifies the non-ancillary data as an iterable of [bytes-like objects](#) (e.g. **bytes** objects); the operating system may set a limit (`sysconf()` value `SC_IOV_MAX`) on the number of buffers that can be used. The *ancdata* argument specifies the ancillary data (control messages) as an iterable of zero or more tuples (`cmsg_level, cmsg_type, cmsg_data`), where *cmsg\_level* and *cmsg\_type* are integers specifying the protocol level and protocol-specific type respectively, and *cmsg\_data* is a bytes-like object holding the associated data. Note that some systems (in particular, systems without **MSG\_SPACE()**) might support sending only one control message per call. The *flags* argument defaults to 0 and has the same meaning as for `send()`. If *address* is supplied and not `None`, it sets a destination address for the message. The

return value is the number of bytes of non-ancillary data sent.

The following function sends the list of file descriptors *fds* over an **AF\_UNIX** socket, on systems which support the **SCM\_RIGHTS** mechanism. See also **recvmsg()**.

```
import socket, array

def send_fds(sock, msg, fds):
    return sock.sendmsg([msg], [(socket.SOL_SOCKET,
```

**Availability:** Unix, not WASI.

Most Unix platforms.

Raises an **auditing event** `socket.sendmsg` with arguments `self`, `address`.

*New in version 3.3.*

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an

**InterruptedError** exception (see **PEP 475** [<https://peps.python.org/pep-0475/>] for the rationale).

```
socket.sendmsg_afalg([msg, ]*, op[, iv[, assoclen[, flags]]])
```

Specialized version of **sendmsg()** for **AF\_ALG** socket. Set mode, IV, AEAD associated data length and flags for **AF\_ALG** socket.

**Availability:** Linux >= 2.6.38.

*New in version 3.6.*

```
socket.sendfile(file, offset=0, count=None)
```

Send a file until EOF is reached by using high-performance **os.sendfile** and return the total number of bytes which were sent. *file* must be a regular file object opened in binary mode. If **os.sendfile** is not available (e.g. Windows) or

*file* is not a regular file `send()` will be used instead. *offset* tells from where to start reading the file. If specified, *count* is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is updated on return or also in case of error in which case `file.tell()` can be used to figure out the number of bytes which were sent. The socket must be of `SOCK_STREAM` type. Non-blocking sockets are not supported.

*New in version 3.5.*

`socket.set_inheritable(inheritable)`

Set the `inheritable` flag of the socket's file descriptor or socket's handle.

*New in version 3.4.*

`socket.setblocking(flag)`

Set blocking or non-blocking mode of the socket: if *flag* is false, the socket is set to non-blocking, else to blocking mode.

This method is a shorthand for certain `settimeout()` calls:

- `sock.setblocking(True)` is equivalent to `sock.settimeout(None)`
- `sock.setblocking(False)` is equivalent to `sock.settimeout(0.0)`

*Changed in version 3.7:* The method no longer applies `SOCK_NONBLOCK` flag on `socket.type`.

`socket.settimeout(value)`

Set a timeout on blocking socket operations. The *value* argument can be a nonnegative floating point number expressing seconds, or `None`. If a non-zero value is given, subsequent socket operations will raise a `timeout` exception if the timeout period *value* has elapsed before the operation has completed. If zero is given, the socket is put in non-blocking mode. If `None` is given, the socket is put in blocking

mode.

For further information, please consult the [notes on socket timeouts](#).

*Changed in version 3.7:* The method no longer toggles `SOCK_NONBLOCK` flag on `socket.type`.

`socket.setsockopt(level, optname, value: int)`

`socket.setsockopt(level, optname, value: buffer)`

`socket.setsockopt(level, optname, None, optlen: int)`

Set the value of the given socket option (see the Unix manual page [setsockopt\(2\)](#)). The needed symbolic constants are defined in the `socket` module (`SO_*` etc.). The value can be an integer, `None` or a [bytes-like object](#) representing a buffer. In the later case it is up to the caller to ensure that the bytestring contains the proper bits (see the optional built-in module `struct` for a way to encode C structures as bytestrings). When `value` is set to `None`, `optlen` argument is required. It's equivalent to call `setsockopt()` C function with `optval=NULL` and `optlen=optlen`.

*Changed in version 3.5:* Writable [bytes-like object](#) is now accepted.

*Changed in version 3.6:* `setsockopt(level, optname, None, optlen: int)` form added.

[Availability](#): not WASI.

`socket.shutdown(how)`

Shut down one or both halves of the connection. If `how` is `SHUT_RD`, further receives are disallowed. If `how` is `SHUT_WR`, further sends are disallowed. If `how` is `SHUT_RDWR`, further sends and receives are disallowed.

[Availability](#): not WASI.

`socket.share(process_id)`

Duplicate a socket and prepare it for sharing with a target process. The target process must be provided with *process\_id*. The resulting bytes object can then be passed to the target process using some form of interprocess communication and the socket can be recreated there using `fromshare()`. Once this method has been called, it is safe to close the socket since the operating system has already duplicated it for the target process.

**Availability:** Windows.

*New in version 3.3.*

Note that there are no methods `read()` or `write()`; use `recv()` and `send()` without *flags* argument instead.

Socket objects also have these (read-only) attributes that correspond to the values given to the `socket` constructor.

`socket.family`

The socket family.

`socket.type`

The socket type.

`socket.proto`

The socket protocol.

## Notes on socket timeouts

A socket object can be in one of three modes: blocking, non-blocking, or timeout. Sockets are by default always created in blocking mode, but this can be changed by calling `setdefaulttimeout()`.

- In *blocking mode*, operations block until complete or the system returns an error (such as connection timed out).
- In *non-blocking mode*, operations fail (with an error that is

unfortunately system-dependent) if they cannot be completed immediately: functions from the `select` module can be used to know when and whether a socket is available for reading or writing.

- In *timeout mode*, operations fail if they cannot be completed within the timeout specified for the socket (they raise a `timeout` exception) or if the system returns an error.

## Note

At the operating system level, sockets in *timeout mode* are internally set in non-blocking mode. Also, the blocking and timeout modes are shared between file descriptors and socket objects that refer to the same network endpoint. This implementation detail can have visible consequences if e.g. you decide to use the `fileno()` of a socket.

## Timeouts and the `connect` method

The `connect()` operation is also subject to the timeout setting, and in general it is recommended to call `settimeout()` before calling `connect()` or pass a timeout parameter to `create_connection()`. However, the system network stack may also return a connection timeout error of its own regardless of any Python socket timeout setting.

## Timeouts and the `accept` method
